3 non-neonates became confused, and 1 of them had a parkinsonian tremor This was attributed to overdosage of chlorpromazine 2 of these patients, who died, were receiving more than 1 g of chlorpromazine daily The 3rd, with confusion plus tremor, was receiving 600 mg daily and recovered A neonate died on the eleventh day after receiving chlorpromazine 360 mg daily for several days His tetanus was controlled At necropsy only pulmonary œdema was found, and death was thought to be due to chlorpromazine poisoning In 1 patient (not included in this trial) intravenous amylobarbitone 500 mg, followed by the same dose half an hour later, did not control the spasms for more than fifteen minutes after each injection An intravenous injection of 100 mg of chlorpromazine thirty minutes after the second dose of amylobarbitone was followed by rapid relaxation The patient became comatose in ten minutes It was more than twelve hours before the spasms recurred, and they remained mild for several more hours This was considered to be due to the well-known potentiating effect of chlorpromazine on barbiturates

Clinically chlorpromazine relaxes tetanus spasm more effectively than do barbiturates, unless the latter are given in large enough dose to cause loss of consciousness Retention of consciousness and absence of clinical respiratory depression seem to be an advantage

Barbiturates

The amylobarbitone-phenobarbitone combination was easily manipulated in the non-neonates, but we felt that equally good results could have been obtained with amylobarbitone alone In the neonates phenobarbitone proved to be cumulative, and after the first two or three days as little as 30 mg daily sometimes sufficed to keep the child well sedated There is no doubt that a few neonates were oversedated, and that this contributed to death, but it would give a false impression of accuracy to give a figure for the incidence of this To find the smallest dose adequate to control the convulsions without causing respiratory depression is not easy, and sometimes the latter must be accepted as the price of freedom from convulsions Prolonged use of phenobarbitone in neonates may be undesirable because of its slow metabolism and excretion Amylobarbitone may well be the preferable drug

Prophylactic Antitoxin

A male African, aged 45, had 1500 I U of antitoxin given after multiple stab wounds He had an incubation period of fourteen days and no premonitory symptoms He was treated with barbiturates and died after two days

Comparison of Treatment Groups

The more important features of the two treatment groups are compared in tables I and II There are no statistically significant differences

Mortality-rates (*Table III*)

The trial was stopped at a total of 75 cases because no statistically significant differences had emerged and because each treatment had its disadvantages The high death-rate in the neonate chlorpromazine group may well be due to chlorpromazine poisoning A second trial of chlorpromazine against a mixture of barbiturates and chlorpromazine was begun and will be reported later

Since some patients survived only a few hours after admission to hospital and can hardly be said to have had any treatment, the death-rate of those surviving more than twenty-four hours in hospital is given separately

Complications and Feeding (*Table IV*)

Necropsies were made on all those who died, except 1, by the department of pathology of the University of Natal and by the pathologists of the Government mortuary The figures for complications are therefore more accurate for the patients who died than for those who recovered Pneumonia was suspected before death in a few patients, usually neonates, whose lungs were found at necropsy to be uninfected Chest radiographs were not taken during the stage of severe tetanus

Although not reaching the conventional level of statistical significance, the absence of pulmonary complications in the chlorpromazine group of non-neonates is striking and may be of importance Furthermore stomach-tubes were passed with greater ease in the chlorpromazine than in the barbiturate group The chlorpromazine group of non-neonates needed a tube less often, and patients were able to swallow throughout the illness more often than the barbiturate group

The "other important complications" included drug overdosage, laryngospasm, malnutrition, fractured vertebræ, bilharziasis, pulmonary tuberculosis, accidental overhydration, dagga (*Cannabis indica*) addiction, acute pyelitis, abortion, fractured skull with epilepsy, gonococcal ophthalmia, prematurity, changing from breast to artificial milk during the illness, cerebral thrombosis, jaundice, and severe nasal sepsis It is impossible to assess the part some of these played in the patients who died Convulsions are not the immediate cause of death in tetanus as often as is commonly assumed Necropsy is not so helpful as could be hoped It is possible that direct action of the toxin on the vasomotor and respiratory centres is the most important factor

Tracheotomy

It is generally agreed that pulmonary complications are an important cause of death in tetanus, and in this trial, in which no tracheotomies were done, the development of pneumonia, after treatment had begun, was common in all except the chlorpromazine-treated non-neonates, among whom, despite oral feeding in half the cases and the use of a stomach-tube in most of the remainder, there were only two cases of pneumonia after admission to hospital

There were three reasons why it was decided only to do tracheotomy on patients if and when conclusive indications appeared

(1) There is no proof that tracheotomy improves the prognosis, whereas it certainly complicates management

(2) It carries its own complications Forbes and Auld (1955) did tracheotomy on 10 patients, in 7 of whom mediastinal emphysema, atelectasis, or pneumonia developed 5 of their patients required bronchoscopy, 3 of them more than once

(3) The prospect of doing tracheotomy on seriously ill children, often aged less than 1 week, was sufficiently alarming to be avoided in the absence of conclusive evidence of its value

Looking back over the series we feel that tracheotomy would have been desirable at least in cases where laryngospasm developed, but these were few (3) and unpredictable The suggestion that tracheotomy is obligatory in patients fed orally or by stomach-tube is certainly reasonable, and it is hoped to obtain evidence on this matter in a later trial The tendency of neonates to regurgitate probably renders tracheotomy (and intravenous feeding) especially necessary in that group We are disinclined to accept this indication absolutely because tetanus is common in areas where technical facilities are comparatively few, and overloading the essential schedule of treatment with conceivably unnecessary tracheotomy is to be, avoided if possible Routine intravenous feeding is even more impracticable The practice of routine tracheotomy in centres specially experienced in treating respiratory disease and poliomyelitis, and where tetanus is only occasionally met with, is as justified as routine tracheotomy in this series would have been unjustified

Laryngospasm

Severe laryngospasm provoked by stimulation (passage of a nasal tube or an injection) developed in 3 cases, all in the barbiturate non-neonate group 2 of the patients died, apparently as a result In both of these sedation was manifestly inadequate, but the surviving patient appeared to have been well sedated

Sudden Arrest of Respiration

This happened thrice in 1 non-neonate (an Indian male aged 7 years), and manual artificial respiration was followed by return of spontaneous respiration in a few minutes on the first two occasions The third occasion was fatal

Similar repeated respiratory failure developed in 3 neonates who died and in 1 who survived Since neither respirators suitable for neonates nor the staff to manage them were available, the question of whether to use continuous artificial respiration with or without neuromuscular block did not arise It is impossible to say how often patients who died would have started breathing again, at least temporarily, if someone had been at hand to give artificial respiration Of the 5 patients who had more than one attack of respiratory failure, 4 were treated with barbiturates and 1 with chlorpromazine Respiratory stimulants (nikethamide, bemegride) were given as well as artificial respiration, without apparently making any difference Periods of gasping respiration were common before death in the neonates

Prognostic Criteria (*Table V*)

The period of onset is the most important criterion of prognosis The incubation period is unreliable because the time of wounding (or birth) from which it is calculated may not be the time of infection, and because there are patients in whom no attributable wound is found It is usually considered that a period of onset of less than forty-eight hours carries a serious prognosis In all our groups the average period of onset was forty-eight hours or less, indicating that the tetanus was usually very severe Some patients denied any symptoms before the onset of reflex spasms However, death and survival were by no means closely related to the duration of the period of onset 9 non-neonates with periods of onset of less than twenty-four hours survived It is not rare to read reports of a few, or even single, cases of tetanus in which it is stated that the patient would have died because of a short incubation period or period of onset, and that survival must be attributed to the treatment given Such claims are unacceptable because these prognostic criteria are only general guides and give no certain information on the outcome of an individual case Tetanus does not differ from other infections in that properly designed clinical trials are necessary if the value of a treatment is to be determined with the greatest economy of lives

Comparisons of mortality figures between one published series of tetanus and another are also liable to be misleading because, for example, the quality of the nursing may well be more important than the drugs used Reports of single cases are only of value in describing new techniques, they give no conclusive proof of the efficacy of a treatment There have been reports of administration of chlorpromazine to tetanus patients dating from its introduction into anæsthetic practice in combination with pethidine and promethazine The specific tetanus anticonvulsant action does not seem to have been suspected at first, with the result that small doses were given and chlorpromazine was never used alone, which is the only way of evaluating it In fact phenothiazine compounds are the most potent available substances which may arrest tetanus spasms without significantly depressing respiration or consciousness (D R Laurence and R A Webster, unpublished) It remains to be seen what part these drugs will play in the treatment of tetanus, because it is by no means certain that mere control of convulsions together with prevention of pneumonia will ensure survival in all cases

Summary

A clinical trial was made on 75 tetanus patients allotted at random to two treatments practised concurrently

Chlorpromazine and barbiturates, when used as described, cause no statistically significant difference in the outcome of tetanus

Chlorpromazine is easier to manage than barbiturates because it controls tetanus convulsions without causing loss of consciousness or clinically noticeable respiratory depression.

We thank Dr D D Reid for advice on the design of the clinical trial as well as for preparing the envelopes with which the patients were randomised, Dr S Disler, medical superintendent, King Edward VIII Hospital, Durban, for facilities for the clinical trial, and Maybaker Pty for a gift of chlorpromazine Dr D R Laurence visited the department of medicine of the University of Natal in 1956 with a grant from the Wellcome Trust

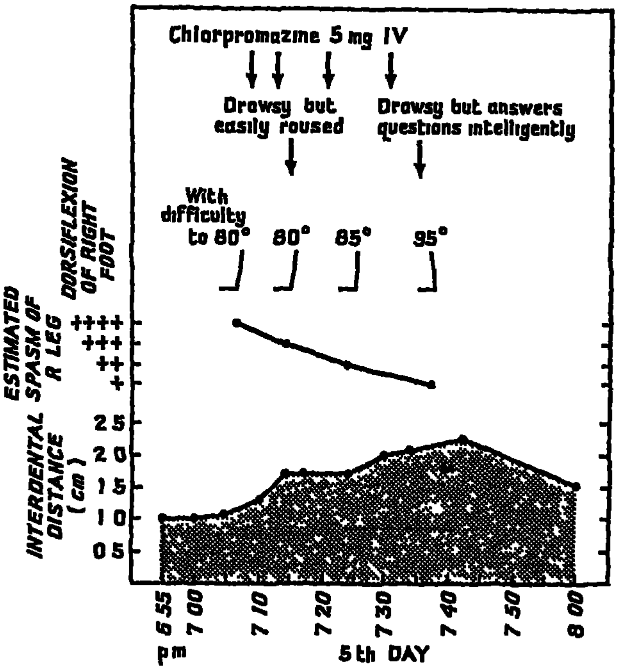
EFFECT OF CHLORPROMAZINE ON MUSCLE SPASM IN HUMAN TETANUS

MARGARET N BARR
M B, B Sc Edin, D Obst, F F A R.C S
RESEARCH ASSISTANT IN ANÆSTHESIA, UNIVERSITY OF ST ANDREWS, AT QUEEN'S COLLEGE, DUNDEE

TETANUS may be general, local, or a combination of both In man local tetanus is relatively uncommon, but it is readily produced experimentally Hougs and Andersen (1954) and Kelly and Laurence (1956) studied the effect of drugs of possible therapeutic value on the muscle spasm of local tetanus in the rabbit Since chlorpromazine showed promise it was given to patients with general tetanus Kelly and Laurence, in their successful treatment of a child, used it alone to combat the spasms, they discuss its probable mode of action Other workers have combined chlorpromazine with depressants of the central nervous system and with neuromuscular blocking agents, but opinion differs about the value of chlorpromazine



Effect of intravenous chlorpromazine on trismus and muscle spasm of right leg (See text for explanation of terms and symbols used in diagram)

I report here a case of tetanus with mainly local manifestations because chlorpromazine immediately and unequivocally reduced the muscle spasm

Case-report

A girl, aged 11 years, injured her foot on some old wood on Feb 2, 1957 The wound suppurated, and on Feb 17 trismus developed Late on Feb 18 she was admitted to hospital, complaining only of trismus and hunger She denied stiffness of either leg or any other symptom Her previous health had been excellent, and she had not been actively or passively immunised against tetanus

On examination she looked well and was apyrexial, but could not separate her teeth more than 1 cm —attempts to do so decreased this distance There was a suppurating puncture wound on the medial side of her right sole Muscle spasm held her right foot in inversion and plantar flexion, and her right knee was flexed Both knee- and ankle-jerks were exaggerated, with poorly sustained clonus, more especially on the right Her left leg was otherwise normal Her arm, abdominal, and plantar reflexes were normal, and the rest of the clinical examination was negative

Treatment and Progress

Treatment began with antitetanus serum, wound toilet under general anæsthesia, penicillin, and intravenous infusion Sodium phenobarbitone gr, 2 at 2 A M and gr 3 at 7 A M was given intramuscularly, and phenobarbitone gr 1 was given orally thrice during that day The patient became deeply sedated though rousable for fluid feeds, but by evening the trismus and spasm of her right leg had worsened Phenobarbitone was stopped and a trial of chlorpromazine started, the interdental distance—i e , the distance in centimetres between the edges of the incisors when the patient opened her mouth as widely as possible—being used as a measure of its efficacy

The first dose (at 6 P M on third day of illness) had a dramatic effect Before treatment with chlorpromazine the interdental distance had been 1 cm and the knee-jerks exaggerated (examination was limited because it made the spasm worse) Immediately after the slow intravenous injection of chlorpromazine 20 mg the interdental distance was 2 5 cm , *increasing after six minutes to 3 cm Tendon-reflexes and limb* spasm disappeared, and the patient became sleepier but still easily rousable Her respirations, pulse-rate, and blood pressure were unchanged At midnight she was rousable, but her jaw and right leg were still relaxed and knee-jerks absent, but by 9 A M trismus, spasm of her right leg, and exaggeration of her knee-jerks had returned Liquids only had been taken that morning Chlorpromazine 10 mg increased the interdental distance to 1 9 cm and made the patient drowsy At 2 P M the interdental distance was 1 5 cm , the reflexes were normal, and she had just eaten a three-course lunch By 4 P M trismus, &c , had returned, but chlorpromazine 5 mg reduced it as before It had been noted that day that, if one tried to dorsiflex her right foot, spasm worsened and opposed the movement (response to stretch), but by 10 P M light touch on her right foot elicited a violent painless convulsive "withdrawal" movement characterised not only by contraction of the inverter and plantar flexor muscles of the foot and of the hamstring muscles but also by palpable contraction of the quadriceps muscle The patient had not noticed this convulsive movement occurring spontaneously but she felt the limb "stiff" for the first time that day The severity of limb spasm could now be recorded in two ways (1) the estimated angle from the horizontal to which the right foot could be dorsiflexed (the left foot could be dorsiflexed to 95°), and (2) the degree of reflex spasm, which was arbitrarily graded as follows (in the diagram the symbols are shown vertically)

++++	*Violent "withdrawal" spasm (as described above) on lightly touching the toes of the right foot*
+++	*Similar spasm elicited if foot touched more firmly*
++	Plantar flexion present and increased on dorsiflexing foot
+	Increased tone compared with left limb

In the accompanying figure the effect of intravenous chlorpromazine on trismus and limb spasm is shown diagrammatically *This pattern of response* is typical of that regularly obtained during the fifth and sixth days of the disease Chlorpromazine 20 mg *reduced* trismus *for five* or six hours and limb spasm for a variable but shorter period

On the sixth day thiopentone 50 mg , given two hours after chlorpromazine 20 mg , reduced considerably further, *for a few minutes, trismus and limb spasm, though* consciousness was unimpaired—the child was eating lunch five minutes later This effect was confirmed twice

On the seventh day substitution of chlorpromazine 50 mg six-hourly *for intravenous chlorpromazine* was begun, and treatment with phenobarbitone (gr 1 six-hourly) was started *again When phenobarbitone* was withheld on the tenth day, the patient's improvement continued for twenty-four hours, then the spasm increased, requiring twice as much chlorpromazine to control it Until the thirteenth day any disturbance, such as the entry of students or visitors, had increased the trismus and limb spasm Since on that day it did not, and since the interdental distance was 3 cm , with no appreciable limb spasm, chlorpromazine was withheld, and the child was moved to the main ward The spasm immediately returned, especially that of the limb, therefore treatment with chlorpromazine 100 mg six-hourly was resumed for forty-eight hours, when the spasm again became minimal On the seventeenth day the patient got up, but the increased tone in the calf caused her to walk in equinus for two days When she was discharged on the nineteenth day, her interdental distance was 2 8 cm Six weeks later it was 4 3 cm and she was clinically normal

During treatment there was no complication, and frequent examinations of the blood and urine showed no evidence of jaundice or of depression of the bone-marrow

Discussion

In this child the limitation of muscle spasm to the jaw and one leg facilitated study of the effect on it of drugs and disturbance I do not suggest that the methods described will be useful for assessing ordinary clinical response, because usually it is undesirable to stimulate the patient in this way This child had an excellent prognosis, and recovery was probable even without any sedative or antispasmodic therapy Nevertheless there is no doubt that chlorpromazine modified the spasm and, by relieving her trismus, enabled her to eat a normal diet, and she remained conscious Full phenobarbitone sedation had provided neither advantage A further, though hypothetical, benefit might have been the minimising of contracture—a recognised sequel to local tetanus (Millard 1954) In experimental local tetanus the early reflex or "hypertonic" contraction, which can be abolished by section of the nerve, deep anæsthesia, curarisation, &c, is succeeded in four or five days by "myostatic contracture" This is unaffected by any of the measures mentioned above, but may recover spontaneously in from four to eight weeks (Ranson and Ranson 1929) Its cause is unknown, but, since it is always preceded by reflex spasm, perhaps the spasm in some way damages the muscle, leading to "myostatic contracture" If this were so, the reduction of early spasm by suitable drugs, as was done intermittently in the present case, might minimise subsequent contracture and so shorten disability In this child the time taken for clinical recovery of the muscles compares favourably with the much longer periods—up to several months—reported by some workers (see Millard 1954)

The effect of the initial dose of chlorpromazine, given during deep phenobarbitone sedation, was never matched by subsequent and larger doses, and thiopentone, given during the period of action of chlorpromazine, temporarily but considerably increased the interdental distance These facts suggest that a combination of phenobarbitone and chlorpromazine, as used by Cole and Robertson (1955), might be superior to chlorpromazine alone This theory was not tested by parenteral dosage, but the response to the combination given orally seemed to favour it No conclusion however, was reached

Summary

An unusual case of tetanus is reported in which it was possible to measure roughly the effect of drugs and disturbance on spasm

Full sedative doses of phenobarbitone did not relieve the spasm, but chlorpromazine did

I am grateful to Prof D M Douglas for allowing me to assist in the treatment of his patient and to publish this case I was in receipt of a grant from the Scottish Hospital Endowment Research Trust

"A young lady keeps her bed for two or three years for an affection of the hip, and is seen by all the leading men in London One day the clergyman walks in, prays over her, and she gets up and walks The case is reported in all the religious journals as a miracle, whereupon the doctors all join in declaring that the case was one of hysteria, and that there was nothing the matter with her Then, I would ask, why was that girl subjected to local treatment and to the infliction of physic every day for years? Why did not the doctors do what the parson did?"—SIR SAMUEL WILKS *Lectures on Diseases of the Nervous System* London, 1878, p 374

ISOLATION OF TRACHOMA VIRUS IN EMBRYONATE EGGS

L H COLLIER
M D Lond
HONORARY DIRECTOR, M R C TRACHOMA RESEARCH GROUP,
LISTER INSTITUTE, LONDON, S W 1

J SOWA
B A Dubl
BACTERIOLOGIST, M R C TRACHOMA RESEARCH GROUP,
FAJARA, GAMBIA, WEST AFRICA

THE laboratory cultivation of trachoma virus has long been attempted by different workers, but claims to success (Machiavello 1944, Stewart and Badir 1950, Poleff 1950, 1954) have not been confirmed The expert committee on trachoma of the World Health Organisation (1956) was not convinced that the cultivation of the virus had been achieved in series or in quantity

T'ang et al (1957), however, in China, made three isolations of a virus from patients with trachoma by inoculating conjunctival material into the yolk sacs of 6–8-day embryonate eggs The egg-cultured virus produced a follicular conjunctivitis in rhesus monkeys, in one instance with inclusion bodies Various animal and other tests distinguished the virus from hitherto described viruses, in particular those of psittacosis and lymphogranuloma, which it resembled morphologically

Our preliminary results recorded here have confirmed the findings of the Chinese workers with the isolation of a morphologically and serologically similar virus from patients with trachoma in the Gambia, and have identified it as the causal agent of trachoma by inoculation of a human subject

The Chinese Virus

Dr T'ang kindly supplied us with freeze-dried samples of his strains of virus, which were brought from Peking in September, 1957, by Prof E T C Spooner Strains TE8 (13th egg passage) and TE55 (8th egg passage) were revived without difficulty in the yolk sacs of 8-day embryonate eggs incubated at 35°C as recommended by T'ang In general we confirmed the original morphological description of the virus, its lethal effect on chick embryos, however, was not so constant as reported by T'ang Both strains have now undergone 6 egg passages at the Lister Institute After 2 egg passages three young rhesus monkeys were inoculated with strain TE55 by the conjunctival route Two monkeys developed follicles in the upper fornix of the inoculated eye on the 8th and 20th days The follicles persisted for about 8 weeks, the control eyes remaining normal throughout Although cytoplasmic inclusions were occasionally found in scrapings from the infected conjunctivæ they were never typical of the classical Halberstaedter-Prowazek (1907) bodies

Isolation of Virus from Trachoma Patients in the Gambia

Our viruses were isolated by methods similar to those of T'ang et al (1957) To avoid any possibility of confusion, live Chinese virus was never sent to the West African laboratory.

Method of Isolation

Material was taken from patients in whom typical trachoma inclusions had recently been found The upper lid was everted and rubbed with a swab moistened with 10% broth-saline The swab was placed in broth-saline 0 5 ml which contained streptomycin 500 µg to inhibit bacterial contaminants, and held for an hour at 4°C (Penicillin was not used, because the Chinese workers reported it to be antiviral) The fluid, including that squeezed from the swab, was used to inoculate 2-day, 5-day, or 6-day embryonate eggs by the yolk-sac route Viruses closely resembling the Chinese strains were isolated from 10 trachoma patients They were freeze-dried as crude yolk-sac homogenates in 2 5% peptone and sent by air-mail to the Lister Institute The following notes illustrate a typical isolation

Case 1.—A Mandingo girl, aged 8 years, was examined on May 20, 1957, with the slit-lamp by Mr M Gilkes, who reported trachoma III, follicles+, papillæ+++, scarring+, well-developed 5-mm pannus, and slight corneal infiltration in advance of pannus No inclusions were found in conjunctival scrapings

On Nov 20 she was Frei-test negative after 48 hours

On Nov 27 inclusions were found in conjunctival scrapings, and conjunctival material was injected into two eggs

On Dec 6 one embryo died A yolk-sac smear stained by Castañeda's method showed numerous elementary bodies

This strain of virus, designated G1, was passaged four times in eggs before dispatch to the Lister Institute (see table) It has now undergone ten yolk-sac passages made by inoculating the yolk sacs of 6–8-day embryos with 0 25 ml of 20% suspensions of infected yolk sac in 10% broth-saline

INITIAL EGG PASSAGES OF STRAIN G1

Passage no	No of embryos inoculated	No of specific deaths	Days after inoculation on which embryos died
1	2	1	9
2	6	5	8, 8, 8, 9, 9
3	7	5	4, 4, 4, 4, 6
4	9	8	4, 4, 5, 5, 6, 6, 6, 6

Morphology and Staining Reactions

Morphologically the Chinese and the Gambian strains of virus are very similar Smears from infected yolk sacs contained numerous elementary bodies staining red by Machiavello's method, and blue with Castañeda stain Giemsa-stained particles ranged in size from 0 2 to 0 5 μ, the smaller staining pink and the larger blue or purple Most forms were round, and some slightly elongated They occurred singly or in aggregates, mostly extracellularly Some intracellular forms were present, usually as large purple granules, sometimes as big as 1 μ in diameter In one yolk sac infected with a Gambian virus numerous yolk cells were packed with virus particles which stained characteristically with Giemsa and with Castañeda, in this instance the embryo survived, and the yolk sac was removed shortly before hatching was due

Electron Microscopy

Viruses from the 16th egg passage of Chinese strain TE8 and from the 8th egg passage of strain G1 were purified by differential centrifugation and treatment with 'Arcton 63' (1 1 2 trichloro 1 2 2 trifluoroethane) by a method similar to that of Gessler et al (1956)

Electron microscopy revealed objects strikingly similar to the elementary bodies of other members of the *Chlamydozoaceæ* (Rake 1947, Heinmets and Golub 1948, Gaylord 1954) In the electron micrographs (fig 1a and b) the collapsed desiccated bodies measure 0 3–0 4 μ Rather larger forms, not shown here, were also seen No such bodies were found in an extract of normal yolk sac similarly prepared, and it is highly probable that they represent the virus

Action of Virus on Chick Embryos

Although a heavy inoculum of virus usually killed embryos in 4–11 days, this was not the rule, and living embryos examined just before hatching sometimes had numerous elementary bodies in the yolk sac Embryos dying after infection usually, but not always, had petechial hæmorrhages in the skin and intense congestion of the liver and kidneys but apparently a normal spleen In only 2 of 12 embryos dying after infection with strain TE8 were virus-like particles found in smears of the viscera in one they were present in the skin, brain, spleen, liver, lung, and kidney, but in the other only in the skin

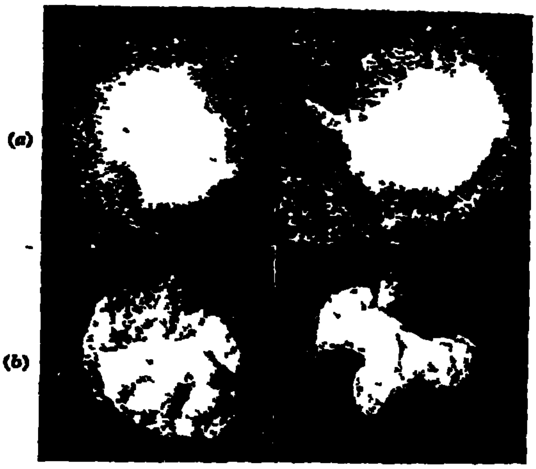

Fig 1—Electron micrographs (×67,000) of virus-like bodies in purified suspensions of (a) strain TE8 and (b) strain G1

Serological Investigations

The serology will be reported in detail elsewhere Direct and cross-tests by complement fixation with sera from lymphogranuloma patients and from Frei-negative trachoma patients, against the psittacosis-lymphogranuloma group antigen and against antigens prepared from strains TE8, TE55, and G1 revealed a very close relationship between all four antigens

Bacteriological Tests

Yolk-sac suspensions infected with both Chinese and Gambian strains of virus have been repeatedly seeded into various culture media, including those suitable for the growth of brucella and pleuropneumonia-like organisms Incubation under various conditions of temperature and atmosphere consistently failed to induce bacterial growth

Inoculation of Man

Discussing the criteria for identification of a cultured virus as the cause of trachoma the World Health Organisation (1956) stated

> "In all cases the final proof should be the production of typical trachoma in human volunteers after sufficient passages in culture to eliminate the dilution factor Although the committee deplores the necessity for human inoculation (not at present a dangerous procedure in view of effective chemotherapy) it insists that this criterion be fulfilled, as at the present time experimental trachoma cannot be diagnosed with certainty in hosts other than man"

It was deemed advisable to use a blind man for such an experiment, to avoid any possible risk to sight On March 11, 1958, such a volunteer was inoculated with strain-G1 virus from the 8th egg passage At this passage the original inoculum had been diluted about 10^{17} times

The blind volunteer was a white man, aged 71, whose right and left eyes were enucleated in 1955 and 1957 respectively after phaco-anaphylactic endophthalmitis Before inoculation the conjunctivæ of the sockets were not inflamed, though both were producing a slight mucopurulent discharge After the instillation of 4% cocaine drops the upper lids were everted, the tarsal conjunctiva and the fornix of the left eye were rubbed firmly with an eye swab soaked in a 20% suspension of infected yolk sac in broth-saline The right eye was similarly treated with a 20% suspension of normal yolk sac (day 0) The man was next seen on day 7 and was examined at intervals thereafter with a slit-lamp

Clinical observations—On day 7 he complained of soreness of his left socket, first noted on day 2 His right socket appeared unchanged and remained so thereafter except for slight hyperæmia (which appeared on day 17) of the lower-lid conjunctiva His left socket had a fairly profuse purulent discharge, and the entire conjunctiva was intensely congested, œdematous, and infiltrated His preauricular glands were neither palpable nor tender On day 10 he was not complaining, and his left socket was rather less congested On day 14 he had considerable papillary hyperplasia of the entire conjunctival surface of his left socket On day 17 there was increased discharge from his left socket, with increasing cellular infiltration On day 21 the conjunctiva of his left lower lid appeared granular, owing to small opaque foci, probably early follicles His left preauricular gland was just palpable and slightly tender On day 28 there was increased infiltration of the entire conjunctiva, otherwise there was no change since the last examination The left preauricular gland was no longer palpable or tender

Laboratory investigations—Cultures made on days 7, 17, and 21 yielded *Corynebacterium xerosis* from both sockets On day 17 two colonies of micrococci were grown from the left socket Examination of the volunteer's blood gave the following initial values Hb 16 6 g per 100 ml , packed cell volume 49%, white cells 9000 per c mm (polymorphs 63%, lymphocytes 33%, monocytes 4%), erythrocyte-sedimentation rate (Wintrobe) 10 mm in 1 hour These values remained substantially unchanged except for an increase in the proportion of polymorphs to 66% on day 14, and a rise in total white-cell count to 11,800 per c mm on day 21 Conjunctival scrapings were taken at each examination, and stained with iodine followed by Giemsa-May-Grunwald or by the latter stain only Scrapings from the right (control) conjunctiva contained only normal epithelial cells and moderate numbers of polymorphs From day 7 onwards scrapings from the left conjunctiva contained numerous polymorphs, on days 7 and 10 there were moderate numbers of lymphocytes, plasma cells, and large mononuclear cells The last three cell types became more numerous from day 14 onwards The epithelial cells often showed vacuolation of the cytoplasm, particularly near the nucleus, and distortion of nuclear structure On day 7 numerous particles were seen resembling elementary bodies, mostly extracellular but sometimes within the cytoplasm of the epithelial cells These bodies became progressively more scanty and were not seen after day 14 On day 7 a few initial bodies were seen in epithelial cells, and there were also very scanty but typical Halberstaedter-Prowazek bodies The presence of a carbohydrate matrix in the latter was proved by staining with iodine (Rice 1936, modified by Gilkes et al 1958), and the typical granular structure demonstrated by subsequent decolorising with alcohol and restaining with Giemsa-May-Grünwald (fig 2a and b) Initial body forms and Halberstaedter-Prowazek bodies (fig 3) became progressively more numerous until on day 21 there were often several visible in a single high-power field On day 14 material was inoculated into three chick embryos, one of which died with characteristic hæmorrhagic lesions 8 days later A yolk-sac smear showed numerous elementary bodies identical with those previously described

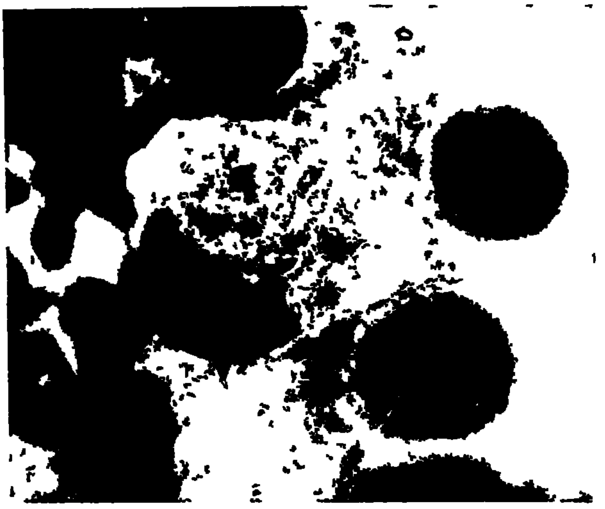

Fig 3—Conjunctival scraping from volunteer inoculated with strain G1 note epithelial cell containing large inclusion which fills cytoplasm and distorts nucleus (Giemsa-May-Grünwald ×1820)

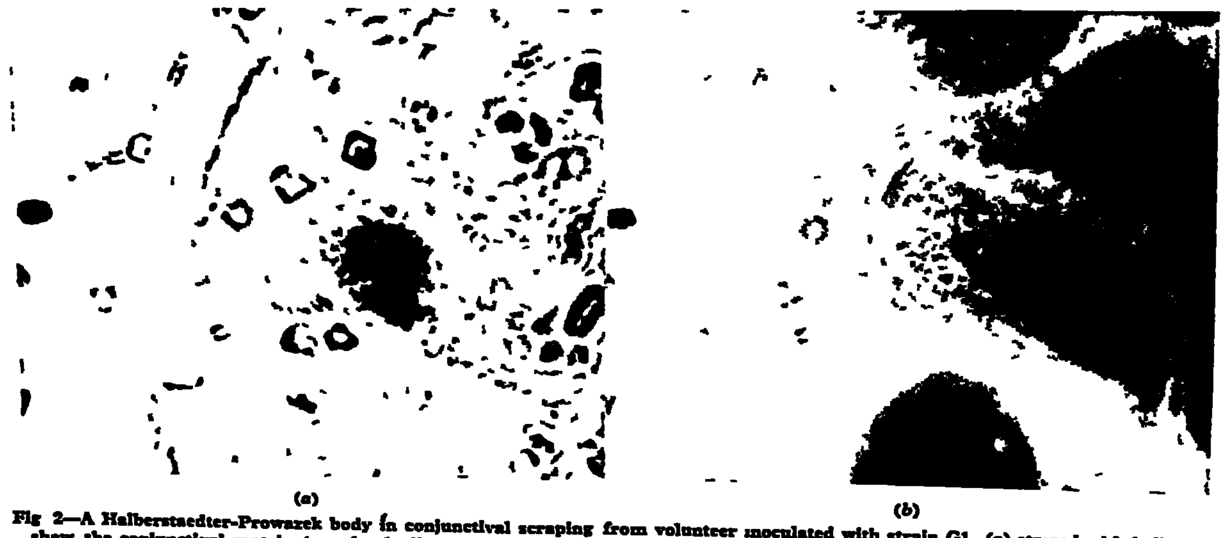
Comment

Our experiments confirm the Chinese workers' findings that a virus resembling those of the psittacosis-lymphogranuloma group can be isolated from trachoma cases by yolk-sac inoculation Our electron microscopy and serological tests provide additional evidence of its



(a)

(b)

Fig 2—A Halberstaedter-Prowazek body in conjunctival scraping from volunteer inoculated with strain G1 (a) stained with iodine to show the conjunctival matrix (angular bodies are crystals of iodide), (b) decolorised and restained with Giemsa-May-Grünwald to show typical location and structure

estimation 2 (at the 5% level) No other statistically significant differences were found with any method of selection in any of the other tests, or in the patients' weights

Decreased platelet-stickiness, compatible with a decreased coagulability of the blood, together with a lowered serum-cholesterol, have therefore been demonstrated in a group of patients with ischæmic heart-disease after dietary restriction, compared with a group of patients with ischæmic heart-disease whose diet was not restricted

Discussion

The present investigation, which was made to determine the effect of a reduction of dietary fat on the coagulability of the blood in ischæmic heart-disease, has disclosed a significant reduction in platelet-stickiness under the conditions of the test Estimation of platelet-stickiness is one of four tests of blood coagulability which have previously been found to differ in patients with ischæmic heart-disease compared to controls, and to reflect hypercoagulability of the patients' blood (McDonald and Edgill 1957) In the remaining three tests (thromboplastin-generation, fibrinogen-estimation, and prothrombin-time) no significant difference was revealed after the diet It should not, however, be assumed, from this relatively brief period of dietary restriction, that blood coagulability as measured by these tests cannot be affected by the intake of fats and other substances in the diet

The difficulty of devising a really low-fat diet for ambulant outpatients is well known The rice-fruit diet was selected because it reduced the dietary fat and because other changes produced by it were fully described (Kempner 1948) The estimation of the 24-hour urine sodium provided independent evidence that the diet had been strictly maintained in an individual patient The serum-cholesterol may be reduced after the rice-fruit diet (Keys 1950), particularly where it has previously been high, a statistically significant reduction of serum-cholesterol was found in the patients studied A diet low in protein, as the rice-fruit diet is, may be accompanied by low serum-cholesterol Ahrens (1957), reviewing the subject, remained uncertain whether the low serum-cholesterol, with diets low in fat, might not be partly due to a low level of dietary protein The decrease in platelet-stickiness and the reduction of serum-cholesterol may be related, but many other humoral changes occur with the rice-fruit diet, a direct relation between these two is not yet proven Further investigation is being made to determine whether the decrease in platelet-stickiness is primarily concerned with changes in the blood-lipids, and, if so, whether it can be related to the dietary intake of any particular fatty compound

Two explanations seem possible for the continued reduction in platelet-stickiness 6–7 weeks after the end of the dietary period Firstly, the effect of the initial dietary restriction may have persisted, and secondly, although these patients were encouraged to resume a more normal diet, some only slightly modified their strict dietary regime, and particularly kept their fat-intake low Amongst Western people today there is a tendency for any patient with ischæmic heart-disease to restrict his intake of fat This factor, operating among the patients who acted as controls, would have tended to lessen the differences shown between those who had dieted and those who had not

The import of the difference in total platelet-counts found in the third method of comparison (low-sodium patients) remains at present uncertain; variation in total platelet counts has been noted at various stages in the natural history of ischæmic heart-disease (McDonald and Edgill unpublished), and seems to be related to platelet-stickiness

Although many patients on the diet claimed subjective improvement, no conclusive evidence was obtained that this regime had either significantly improved their symptoms or altered the course of their disease

Summary

Coagulability of the blood was studied in thirty-four patients with ischæmic heart-disease, before and after half of them had maintained a rice-fruit diet for 4–5 weeks

A statistically significant decrease in platelet-stickiness was found after the diet, together with a statistically significant decrease in serum-cholesterol and other changes No significant difference was found in thromboplastin generation, fibrinogen-estimation, and prothrombin-time (Russell's-viper venom, 'Stypven')

The cooperation and advice of Dr R G Macfarlane, F R S, and Dr Rosemary Biggs have been of the greatest value throughout this work, we express our thanks and indebtedness to them We thank Dr Paul Wood, director of the Institute of Cardiology, who has constantly supported this work, the physicians of the National Heart Hospital, who have allowed us to study their patients, Dr Helen Payling Wright, for advice on the platelet-stickiness test and for the loan of apparatus, Dr J O Irwin, who made the statistical analysis, Dr Denis Baron and Dr Reginald Hudson, for the serum-cholesterol estimations, Miss Wilkinson-Hughes, for help in preparation of the diet, Imperial Chemical Industries Ltd for a grant which covered part of the cost of the investigation, and Burroughs Wellcome and Co for a supply of 'Stypven'

A MODIFIED VEIN-STRIPPER

H Ker
M B Lond, F R C S
SENIOR SURGICAL REGISTRAR, ROYAL GWENT HOSPITAL, NEWPORT, MONMOUTHSHIRE

STRIPPING of the long saphenous vein is now fairly well established as the most useful single procedure in treatment of varicose veins In most cases, however tortuous the superficial veins may appear, the main saphenous trunk is straight enough to allow the stripper to be passed up its whole length from the ankle to the groin, and, if the stripping is complete, not only is the entire vein removed so that recanalisation is impossible but also most of the communications with the deep veins are torn across The superficial varicose tributaries are also disrupted at their junction with the main vein and, since most of them are fed from above by this source, they thrombose or collapse and cause no further symptoms

In about 90% of cases this treatment is sufficient to relieve all symptoms and gives an excellent cosmetic result—an important consideration in a disease many of whose victims are young women Patients requiring further treatment fall into two groups

(1) Those with persistent superficial varicose tributaries, which may be removed by small tenotomy-sized incisions through which they may be fished out with the blunt end of a curved needle

Relationship between serum-haptoglobin level and apparent 50% erythrocyte-survival time (40 determinations in 36 patients with either anæmia or indirect hyperbilirubinæmia) Broken line encloses normal range

The haptoglobin level was determined by the method of Jayle[7] (normal value 109 mg per 100 ml, 95% range 28–190 mg per 100 ml) The erythrocyte-survival time was determined after tagging the erythrocytes with ^{51}Cr in vitro The activity of blood drawn 10 minutes after the injection was taken as 100% (normal 50% apparent survival time 26 days, range 22–30 days) The serum-methæmalbumin level was determined electrophoretically[8]

The results are summarised in the accompanying figure When the survival time was normal, the haptoglobin level was not depressed, whereas patients with 50% apparent survival time of less than 17½ days proved to have ahaptoglobinæmia—i e, no measurable amount of haptoglobin in the serum In the intermediate group with a 50% survival time of 17½–22 days the serum-haptoglobin level was normal or depressed, tending to vary with the survival time

There were two exceptions to these rules, but in these cases the clinical picture was also somewhat unusual

Case 1 had a very short survival time (apparent 50% survival time 9 days), but the haptoglobin level was regularly about 30 mg per 100 ml This patient also had erythropoietic hyperplasia of the bone-marrow, hyperbilirubinæmia, and increased excretion of bile pigments—all signs of increased erythrocyte turnover In spite of this the number of reticulocytes was not increased, nor was there any evidence of active disease (normal erythrocyte-sedimentation rate and normal electrophoretic pattern of serum-proteins)

Case 2 had ahaptoglobinæmia despite a normal survival time of the circulating erythrocytes In this case, too, there was an increased excretion of bile pigments, but the reticulocyte count was normal despite erythropoietic hyperplasia of the bone-marrow This patient appeared to have bone-marrow dysfunction ("bone-marrow hæmolysis") with increased production but low release of erythrocytes

Depression of the haptoglobin level must be due either to decreased production or to increased elimination of haptoglobin Hæmoglobin injected intravenously forms a complex with haptoglobin, which is readily eliminated from the blood-stream After all the haptoglobin has been eliminated in this way, the normal level does not return until after several days

These observations[8] may explain ahaptoglobinæmia in diseases with associated intravascular release of hæmoglobin Judging from the appearance of methæmalbumin in the serum, only 2 of our patients had intravascular hæmolysis, and both had ahaptoglobinæmia Though no certain explanation can be offered for the depression of the serum-haptoglobin level in the other cases, it seems reasonable to assume an increased consumption due to the increased turnover of hæmoglobin

Ahaptoglobinæmia is rare in diseases other than hæmolytic and pernicious anæmia It has been found in hepatocellular failure[2 9] (in which the destruction of the red blood-cells may, however, be increased[10]) and in a few exceptional cases without anæmia[9] Hormone therapy also can influence the haptoglobin level[9 11]

Our preliminary results show that determination of the haptoglobin level is useful in the investigation of anæmia A normal or a raised level argues strongly against hæmolysis, whereas a low level in the absence of hepatic disease indicates hæmolysis Determination of the haptoglobin level is both simple and quick, and it is possible, by repeated determinations, to follow the course of a disease even in patients not in hæmatological equilibrium, in whom the erythrocyte life-span is difficult to assess

The investigation was supported by grants from the Swedish Medical Research Council to B F N and from the Medical Faculty of the University of Lund to M N

BRITISH ASSOCIATION OF PHYSICAL MEDICINE

The annual meeting was held in London on April 25 and 26 under the presidency of Dr P Bauwens

Systemic Manifestations of Rheumatoid Arthritis and Pararheumatic Diseases

Dr A T **Richardson** (London) said that in collagen diseases changes in the serum-globulins were an important factor, but the chemical, physical, and serological reactions in everyday use indicated fundamental differences between these diseases With modern diagnostic techniques such as biopsy, serological tests, and electromyography a firm diagnosis could usually be made But clinical advances were likelier to be mad if the collagen disorders were regarded as separate entities

Dr R M **Mason** and Dr V L **Steinberg** (London) h observed 15 cases of rheumatoid arthritis with [illegible] complications In 6 there was pleural effusion, and [illegible] these the onset of the effusion was closely related to a [illegible] of joint activity Of 9 cases exhibiting diffuse parenchy lung changes, pneumoconiosis or lipoidosis was shown the cause in 4, 1 case was found to be systemic lupus ery matosus (S L E), and the remaining 4, in which no cause cou be found, might be presumed to have "rheumatoid lung" Dr Mason had observed 5 cases of peripheral neuropathy complicating rheumatoid arthritis and 1 case of peripheral neuropathy complicating probable S L E Neuropathy, which appeared to indicate a bad prognosis, was commonly sensory (though motor changes might follow) and usually presented with paræsthesiæ and numbness, generally of the lower limbs Arteritis in association with rheumatoid arthritis had been recognised only quite lately, it was thought to be an infrequen but serious complication It seemed reasonable to conclud that in addition to the frank arteritis of superficial tissues oth complications of rheumatoid arthritis, such as peripheral neur pathy and possibly pleural involvement, might be manifest tions of arteritis It was not clear whether this complic was associated directly with steroid therapy or merely with

severe type of rheumatoid disease that was likely to be treated by steroids, but it seemed that sudden withdrawal of these drugs might set off diffuse necrotising arteritis

Dr A C **Boyle** (London) said that S L E was the commonest of the pararheumatic diseases presenting in departments of physical medicine, by virtue of the frequency of myalgia, arthralgia, or arthritis as the predominant feature This disorder should always be suspected where the symptoms in the joints were out of proportion to objective signs of joint involvement, or where radiographs showed less destructive change than the clinical picture would suggest To the dermatologist S L E presented as a skin disease with involvement of the viscera and sometimes the joints, to the general physician it presented as a general illness, while to the physician in physical medicine it presented as a disease of the joints with involvement of the viscera and sometimes the skin The discovery of the L E-cell phenomenon had made possible the detection of a hitherto unsuspected group of cases which appeared to be low grade and which carried a relatively good prognosis The L E-cell phenomenon was an empirical test, but, in some cases where a diagnosis of S L E was strongly suspected on clinical grounds and yet the test remained negative, a positive result might be obtained by giving the patient 30–40 units of corticotrophin for two to three days and then repeating the test Dr Boyle believed that the L E-cell test was specific for S L E, and a positive result in a case of apparently uncomplicated rheumatoid arthritis heralded systemic involvement The diagnosis of S L E should rest on the clinical features and not on an isolated pathological finding, but conversely a negative L E-cell test did not exclude this diagnosis

Dr S **Mattingly** (London) reviewed clinical and pathological features of some of the rarer collagen disorders In polyarteritis the abdominal manifestations were commonly misinterpreted as an abdominal emergency requiring laparotomy, in the acute stage an acute infection might be simulated Dermatomyositis was associated in about 20% of cases with a malignant tumour Thrombotic thrombocytopenic purpura, a rare condition that was supposedly a "collagen disease" and was thought to comprise a generalised vascular disorder affecting the intima of all small blood-vessels, it might possibly be associated with allergy to drugs and microorganisms The rarer collagen diseases should be considered in the differential diagnosis of obscure joint or muscle pain, particularly when associated with skin lesions, fever, hypertension, or renal disease

Mucoprotein Levels in Rheumatoid Arthritis

Dr C **Feldman**, Dr E V **Hess**, and Mr R L **Markham** had made a long-term assessment of 23 patients with rheumatoid arthritis, including estimation of the two mucoprotein levels, M1 and M2, by photometric scanning following staining of the polysaccharide moiety of the electrophoretically separated fractions, the levels were expressed in arbitrary figures In normal controls the range for M1 was 5–22 units, and for M2 10–26 units In the patients M1 ranged up to 90 units and M2 up to 250 units The range of mucoprotein values was similar in the different stages of disease, except that high values were absent in Steinbrocker's stage I, and the mean values were not significantly different The mean values were much higher in the moderate than in the slight cases, but in the severe cases the values were no higher than in the moderate cases In 6 patients with inactive or slight disease activity M1 showed normal values over a period of at least two months, while the *M2* values remained raised, and in 7 patients with moderate or severe disease activity M1 (but not *M2*) values returned to normal on single occasions This suggested that levels of *M2* more closely reflected the severity of the disease There were wide fluctuations in mucoprotein levels between consecutive readings in individual patients, although the overall pattern correlated satisfactorily with clinical assessment A cautious approach was needed in assessing results of single readings, but serial readings were probably a more reliable aid to clinical assessment than the erythrocyte-sedimentation rate (E S R) or C-reactive protein test

Laboratory Indices in Rheumatic Disease

Dr J H **Glyn** (London) said that it was becoming increasingly clear that the E S R was a fallible guide in screening sorting patients who attended departments of p medicine complaining of ill-defined symptoms In 330 pa with various rheumatic disorders there had been a st correlation between clinical activity and the following te C-reactive protein, total protein-bound polysaccharides, protein, and protein polysaccharides ratio In estab disease these gave fewer false negative readings than the Unfortunately all the tests had been found disappoin unreliable in diagnostic dilemmas, and there was no justi tion for recommending the routine performance of such ti consuming procedures

Therapeutic Trials in Lumbar-disc Degeneration

Dr J **Stewart Lawrence** (Manchester) reported an inve gation into the treatment of miners with pain of lumbar sciatic distribution associated with radiographic evidence disc degeneration but with no neurological signs Immob tion of the lumbar spine by either a plaster ct or bed was found to delay recovery Mobilisation, he other h produced a significantly better result, and manipulation by physiotherapist was more effective than ionisation Acti mobilisation of the spine by exercises was still more effecti Massage produced temporary relief of pain, although appeared to have no influence on the outcome of the mala and did nothing to hasten return to work Cortisone given by mouth to patients in the acute stage of their disability produc no significant difference judging by comparison with simila cases treated by a suspension of cholesterol The value of light spinal support to heavy manual workers as a preventi to future painful and disabling attacks of pain remained unproven

Injuries to the Collateral Ligaments of the Knee Joint

Flight Lieutenant V B **Whittaker** described the results in 83 cases of injury to the collateral ligament No case with associated meniscus or bone injury was included The rati of medial to lateral ligament injuries in this series was 7 1, and, as in meniscus injuries, association football was responsible for the large majority of cases Treatment by complete immobilisa tion, with or without operative repair, produced successful results in a higher proportion of cases (89%) than treatment by other less radical methods, such as heat therapy, strapping manipulation, rest in back splint, or no treatment at all with each of which the success-rate was (50%) Immobilisa tion in plaster-of-paris for five to six weeks was necessary to achieve a good result In the 2 failures recorded in this series of 83 cases immobilisation had been maintained for less than three weeks

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM

The annual congress was held in Cardiff on April 17–19, under the presidency of Mr J J **Healy**

Complications and Treatment of Hypermature Cataract

Mr G T W **Cashell** (Reading) said that of the complica tions of hypermature cataract secondary glaucoma and uveitis were the most important An anterior hypermature lens might prevent glaucoma

Mr C A **Cook** (London) considered the pathological aspects of these complications, which he described under two main headings (1) those leading primarily to the production of glaucoma, and (2) conditions in which the primary pathological change is inflammatory and which may or may not be responsible eventually for a secondary increase in intra ocular pressure Included under (1) were phacolytic glaucoma, the hypermature intumescent lens, and the hypermature dis located lens; and under (2) the so-called lens-induced uveitis, was subdivided into phacotoxic uveitis and endophthal- haco-anaphylactica

J R Hudson observed that the hypermature cataract s common than in the past, and its complications were encountered The early signs of hypermaturity should, absence of any general contraindication, be taken as an ion for operative treatment of a cataract

Fanconi's Syndrome

S J H Miller (London) described a case of Fanconi's ome with pseudofractures which had been treated with rol The calcium deposits that had developed within the were dispersed by maintaining the patient in mild is

Carbonic-anhydrase Inhibitor

M E Langham (London) reported his observations on fect of 'Neptazane' on the intraocular pressure of rabbits nan Neptazane, a new inhibitor of carbonic anhydrase, ed into th[illegible] more readily, while leaving the body more y, than acetazolamide ('Diamox') When neptazane given intravenously both the intraocular pressure and the of formation of the aqueous decreased rapidly

Toxoplasma in Ocular Disease

of C P Beattie (Sheffield) said that toxoplasma had a larly wide zoological and geographical distribution, with revalence of infection in man varying from 5% in Iceland % in Tahiti In this country about a quarter to a half of dult population had been infected In the congenital form, e at least the placental route of transmission was definite, oretinitis was the most constant manifestation, and indeed toxoplasmic chorioretinitis was congenital The acquired tions were usually innocuous, causing only a lymphadeno- y that resembled glandular fever

J K A Beverley (Sheffield) described evidence that in highly immune animals the organism could multiply

r E S Perkins (London) emphasised that there is now statistical, therapeutic, and pathological evidence that plasmosis may cause uveitis in adults as well as a congenital ioretinitis Unfortunately, serological evidence of infec- with toxoplasmosis was common in healthy adults and, e a negative dye test probably excluded toxoplasmosis, a tive test did not prove the ætiology of an individual case of itis Possibly some cases of anterior uveitis were due to plasmosis, but at the moment these cases could not be gnised clinically A positive dye test was common in terior uveitis—particularly acute and subacute cases Cases veitis with a positive dye test were characterised by focal ches of chorioretinitis near the main retinal vessels or the cula or at the margin of the optic disc In many cases the ve lesion was at the edge of an old scar, suggesting that the ority of these lesions were recurrences of congenital infec- s Disseminated choroiditis was not associated with a itive dye test, and was unlikely to be due to toxoplasmosis, the results in retinal vasculitis suggested that toxo- smosis was not a common cause of this condition

Precancerous Melanosis of the Conjunctiva

r M Lederman (London) assessed his results in 14 cases cancerous melanosis at the Royal Marsden Hospital, ndon Of those 14, 12 were submitted to radiotherapy Of se, 2 died of metastases, and the remainder had survived up to seven years, so at any rate some of these tumours re radiosensitive Beta-radiation was to be recommended ause of the relative lack of complications

Chronic Uveitis

Mr A G Cross (London) said that the treatment of chronic itis has been revolutionised by the introduction of the enocortical hormones, which readily damped down the te cases till they had run their usual short and predetermined rse But the outlook, although much better than ten years , was still often grave, blindness resulting

Tolazoline Test

Mr J A E Primrose (London) described the tolazoline ('Priscol') test in glaucoma This test produced a small but transient increase in tension in normal eyes, but in 50 cases of chronic simple glaucoma there was a mean rise in tension of 12 2 mm Hg, while in most cases of narrow-angle glaucoma the response was normal The tolazoline effect was probably due to its influence on the vessels because of an increased formation of aqueous humour

---

Reviews of Books

An Introduction to Experimental Surgical Studies

W J Dempster, F R C S, lecturer in experimental surgery, Postgraduate Medical School of London Oxford Blackwell Scientific Publications 1958 Pp 463 50s

The surgeon today stands like Cortez upon a peak, rubbing his eyes at the new vistas offered to him by the rapid developments in science Yet he must have regrets that many of these visions may be denied to him as realities because of his own limitations By separating the basic sciences so completely from clinical vocation the medical curriculum has in the past effectively sterilised what scientific education most surgeons received, and has conspired with the exigencies of his craft during its anatomical era to rob him of scientific understanding and know-how Yet a new scientific age for surgery has begun and must be carried forward by men who cannot be regarded as professionals in the scientific sense, until a new generation with a different outlook displaces them

The importance of Mr Dempster's work lies in the tacit acceptance of this situation It would, of course, be a herculean task at this stage to develop a book on the application of the basic sciences to surgery, Mr Dempster starts one stage further by providing the surgeon with means of informing himself at the physiological level of experimental empiricism The implication of the word "introduction" in the title should not be misconstrued, for this is not a work for the tyro to read overnight on seeking appointment to a professorial unit It is introductory in the sense that the man tackling a specific problem can find not only an account of the basic work already undertaken in that field but also a useful bibliography, it is crammed with facts and is not armchair reading

To some it may seem that the author's approach has been limited, since he has confined himself to the problems of healing, grafting, transplantation, and low temperature in general, and in particular to the thoracic, genitourinary, gastro-enterological, and cardiovascular aspects But this would be carping criticism, for here is something new arising from an original and courageous conception and completed only with considerable labour Such a book will need frequent new editions since it is valueless if it does not keep up to date, its relatively low price is therefore important Mr Dempster is to be congratulated for his idea, his labour, and the service he has performed

Cancer

Editor Ronald W Raven, F R C S, surgeon, Royal Marsden Hospital, London London Butterworth 1957 Vol 1, pp 557 Vol 2, pp 666 85s each

To produce a System of Cancer is a formidable task at this time of expanding knowledge, and although this work comprises 6 large volumes and an index volume, the specialist must naturally expect to find gaps in the parts which cover his own special interest this could not be otherwise if the work was to be a reasonable size

The first two volumes, which have just appeared, are concerned with research into causation and with the pathology of human tumours Succeeding volumes are to cover epidemiology, occupational cancer, cancer education and detection, clinical aspects, and radiotherapy and chemotherapy The editor contributes several clinical chapters, but the general aim has been to enlist the help of many authors of differing tastes and knowledge to write chapters on their own specialty

To relieve cardiac œdema or pulmonary congestion, it is necessary to reduce the sodium content of the body, an increased excretion of water alone, or of an anion unaccompanied by sodium, is in this context irrelevant In theory the ideal diuretic would increase the amount of sodium filtered by the glomeruli, or diminish directly the amount of sodium reabsorbed by the tubules, in practice the most effective agents at present are those which act primarily by diminishing chloride reabsorption, the increased output of chloride being then accompanied by natriuresis When the general treatment of a cardiac invalid with rest and digitalis is effective, the glomerular filtration-rate (G F R) increases and œdema may be prevented or diminished, so comparatively ineffective diuretic agents may appear to have worked efficiently The diuretic action of theophylline drugs depends mainly on an increase in G F R, and some patients who have become resistant to mercurials may respond once again when aminophylline in a dose of up to 0 5 g is given intravenously two hours after the mercurial injection[6] VOGL[7] advocates the use of oral theophylline preparations as an adjuvant to diuretic therapy Decreased reabsorption of sodium can be directly effected by inducing an osmotic diuresis or by inhibiting the production of aldosterone, which is often increased in œdematous patients[8] Interest in urea as an oral osmotic diuretic has recently been revived[9], but large doses are needed, and the incidence of anorexia and nausea is fairly high The production of aldosterone can be inhibited by amphenone,[10] but the toxic effects of this drug preclude its therapeutic use

Several drugs act mainly by depressing anion reabsorption The carbonic anhydrase inhibitors, which depress bicarbonate reabsorption, are of little value in the treatment of œdema, for they quickly lose their effect as the plasma-bicarbonate level falls, and with it the amount of bicarbonate filtered into the nephron, there is also a tendency to a greater loss of potassium than with mercurial diuretics[6] Since the amount of chloride entering the nephron is normally about three times as great as the amount of bicarbonate,[6] there is a greater potentiality of effectiveness for drugs which depress the reabsorption of chloride rather than of bicarbonate Three groups of drugs have been tested fairly extensively as oral chloruretic agents These are the oral organic mercurials, the aminouracil compounds, and substituted benzothiodiazine (chlorothiazide)

Oral mercurials, such as chlormerodrin ('Merchloran'), may cause diarrhœa, whether because they inhibit fluid absorption in the bowel as well as in the nephron or because the intestinal epithelium is highly susceptible to mercurial toxicity, and we agree with the view of GOODMAN and GILMAN[11]

> "The oral administration of mercurial diuretics obviates the necessity of injection at the price of gastro-intestinal irritation, higher total dosage of mercury, greater danger of systemic mercury poisoning, and a more delayed and less complete diuretic response The route is ineffective when a rapid mobilisation of œdema fluid is desired in an acutely ill individual"

Their final comment applies, we believe, with equal force to the aminouracil compounds While these have some diuretic potency, the incidence of side-effects is high, especially with aminometradine ('Mictine'), the frequency of side-effects is distinctly lower with amisometradine ('Rolicton'), and this drug was found to be of some value in preventing recurrence of œdema which had been got rid of by mercurials[12] The aminouracil compounds quickly lose their effect, and do not really stand comparison with organic mercurials[13] Chlorothiazide is in a quite different category of effectiveness from the oral mercurials and the aminouracil drugs

In potency it is comparable to the mercurials given by injection, and may even produce diuresis in patients who have become resistant to mercurial diuretics[14 15] Favourable clinical reports on its effectiveness in generalised œdema have appeared both in America[14 16 17] and in this country[14 18] It does seem that we now have a potent oral diuretic that not only can control œdema but also, for good measure, has some hypotensive action[19] If our satisfaction at this should appear a little half-hearted, it is because we foresee possible abuse of a drug which, though convenient and potent, is also expensive and not devoid of side-effects Gastrointestinal side-effects seem to be uncommon, but potassium depletion has been observed[14 15], this can be controlled by giving daily supplements of 2–6 g of potassium chloride[15] One patient had an erythematous rash which disappeared when the drug was stopped[17] Hypochloræmia has been observed in patients taking chlorothiazide,[13] but should be controllable by ammonium or potassium chloride The cost is also of some importance According to a pricing bureau the basic cost to the N H S of three injections of mersalyl is 1s 5d, whereas the basic cost of 8 g of chlorothiazide is 9s 10½d, the cost of a week's treatment of œdema is thus more than six times as great with present oral treatment No doubt the need to give injections carries substantial overheads above the basic cost, but at least the diuretic has been given, and there is no box of tablets to constitute a problem of domestic pharmacognosy or of self-medication in the next minor illness

Chlorothiazide certainly represents a great advance in diuretic treatment May we hope that it will become cheaper, that it will not replace the well-tried mercurials until we know more of its side-effects, and, above all, that it will not be used to treat every patient with hypertension, or who complains of breathlessness or swelling of the ankles

Tetanus

TETANUS has been recognised as a killer since its lescription by HIPPOCRATES. By reason of the mode of nfection, the distressing signs, and the difficulty of reatment, it is a dramatic disease. The extent of its menace varies widely from one country to another. Among European countries, it kills each year 22 per million in France, Spain, and Yugoslavia, compared with only 1.7 per million in Great Britain.[1] In agricultural communities the incidence is, of course, higher, and in Brazil in the first quarter of the century the mortality was 178 per million. The efficacy of preventive inoculation is beyond question. In the first six months of the 1914–18 war there were 17,800 cases of tetanus among half a million wounded. Between 1942 and 1945 there were only 12 cases of tetanus in the United States Army,[2] in which preventive inoculation was the rule. Part of this reduction was doubtless due to the absence of horses in the latter period, but the contrast is nevertheless impressive.

Tetanus is not yet so rare as to be unimportant, but in Great Britain it *is* so rare that few people or groups can number more than a handful of cases in their experience. This makes it difficult to evaluate any new treatment, and important to draw as many conclusions as possible from collective experience. The three papers appearing in our present issue and the previous one should be considered in conjunction with last year's report from the Charity Hospital, New Orleans.[3] In the previous fourteen years as many as 558 cases were treated at this hospital. The span of fourteen years was divided into two equal periods, in the second of which antibiotics, tracheostomy, muscle relaxants, and gastrostomy were adopted. This provided as good an opportunity as any that is likely to arise to establish the value of these newer forms of treatment. The mortality was 10% lower in the second period than in the first. But even this modest reduction is robbed of much of its significance by the fact that there has been a steady decrease in mortality during the past fifty years, and the New Orleans workers hold that general supportive care is more important than any single component of treatment.

Of the newer forms of therapy, the muscle relaxants seem to offer great possibilities, and those who have faced the difficulties of their continued use for days or weeks and at last seen the patient go home cured (as did Dr WILTON and his colleagues, whose paper appeared last week) would be unwilling to agree that this is an unimportant advance. The idea behind it—of converting a spastic patient whose respiratory mechanism is out of control into a flaccid patient whose respiration will accept control—has an appeal which is strengthened by the success of the modern treatment of respiratory paralysis. The slightness of the apparent effect of the relaxants on the mortality in the American series may be attributable to insufficient dosages, for they were not used at the Charity Hospital in the manner recommended by their advocates in this country.

Another drug which may have an important place in the treatment of tetanus is chlorpromazine, which is the subject of the papers this week by Dr LAURENCE and his colleagues and by Dr BARR, and its use has been reported by many other workers, including those from the Charity Hospital. Undoubtedly chlorpromazine can dramatically reduce spasticity, sometimes without greatly clouding consciousness or causing significant respiratory depression. LAURENCE et al. describe a valid comparison between chlorpromazine and the barbiturates. In this trial chlorpromazine did not appear to save more lives than the barbiturates, though its administration was easier to manage.

Despite a wealth of reports, we are still in doubt about the best method of treating this challenging disease. For instance, we still have no clear evidence whether hypertonia is better offset by muscle relaxants or central depressants. On the other hand, in the past five or six years we have learnt a good deal about the management of respiratory inadequacy. As it is this that usually kills the patient who succumbs to tetanus we might feel optimistic, but those with experience in treating the disease know only too well how commonly, despite all precautions, an unexpected asphyxial crisis carries the patient off. Even if we could always avoid asphyxia and invasion of the lungs, some patients with severe tetanus might inevitably succumb instead to fixed neurotoxin, which many believe to be unassailable by antitoxin.[4] A short incubation period and a rapid march of symptoms denote a bad prognosis, but not a hopeless one; several very severely afflicted patients have been saved by careful treatment. Clinicians differ in their choice of drugs, but protection of the lungs from invasion, the annulment of hypertonia, the maintenance of adequate respiratory exchange, and tireless supportive care clearly remain the foundations on which treatment should be based.

Annotations

THE OUTPATIENT DEPARTMENT

THE proper function of the outpatient department has hitherto not been given sufficient thought. A discussion by the hospital section of the Royal Society of Health at its congress in Eastbourne last week was therefore most opportune. In this discussion Dr John Fry pointed out that there has been a tendency to over-stress the role of the hospital in providing inpatient care and to neglect the work of the outpatient department, whereas in terms of service to the public the outpatient department is far more important. He suggested that there is an urgent need to look into the present functions and work of the outpatient department and to plan for the future.

Dr A. G. Emslie thought that patients usually much prefer, instead of being admitted to hospital, to attend as outpatients, for this disturbs their home life less. Owing to great advances in radiological and pathological techniques and in therapy, many more patients than formerly can now be investigated and treated as outpatients. It was agreed that this trend should be encouraged, and the functions of the outpatient department will clearly have to be reconsidered Dr Fry sees the outpatient departments filling three main roles—that of consultation centre, that of diagnostic centre, and that of supplying special investigations and treatment

[4] Ransom, F. *Lancet*, 1917, ii, 928.

Dr Emslie emphasised that outpatient work should include radiological and pathological investigations, and the almoner service is another important element Dr Fry pointed out there is considerable variation between general practitioners in the number of patients they refer to consultants Do these differences depend, he asked, on individual factors such as the doctor's age, his education, the size of his list, or his family responsibilities? The discussion showed that we really need to know more of the medical, social, and other factors that may influence referral The average family doctor refers to the consultant in hospital only some 10% of his cases, but where radiological and pathological facilities are afforded to general practitioners these facilities are extensively used Fry himself, out of about 5000 patients at risk in any one year, refers 450 to a consultant, either as outpatients or as inpatients, and a further 320 directly to the radiological department and 375 to the pathological department

There is no doubt that the use of outpatient departments will increase in the future, and it seems sensible to foster this increase by devoting capital money to the construction or extension of these departments Allowance will have to be made for further special facilities—including provision for electrocardiographic examinations and investigations with radioactive isotopes In time the outpatient department may establish itself as the main link not only between the general practitioner and the hospital but also between the preventive services, directed by the medical officer of health, and the hospital Those participating in the discussion agreed that outpatient facilities should be associated with existing hospitals, and some doubt was expressed as to the value of "peripheral clinics" for diagnosis and consultation There is much scope for research in the design of outpatient departments—including if possible the provision of outpatient beds in addition to casualty-recovery beds where patients can be retained for six to eight hours for observation or for minor surgical or medical procedures

POSTOPERATIVE PAROTITIS

PAROTITIS not due to mumps was recognised as a complication of febrile illness, notably typhus, by Stephen Paget[1] He recorded that parotitis, sometimes with suppuration, might follow diseases in the abdomen or pelvis without any signs of pyæmia or septicæmia Paget and some of his contemporaries believed that this complication arose because of some complex connection between the parotid gland and the peritoneum and generative organs—a development of the observation by Hippocrates that orchitis was a complication of mumps

Parotitis sometimes follows operation The exact pathogenesis is uncertain, but the infection, which is usually staphylococcal, probably reaches the gland by way of the parotid duct Dryness of the mouth resulting from a poor flow of saliva and lack of attention to oral hygiene are recognised predisposing factors In 1955 Robinson[2] concluded, from a survey of hospital records, that parotitis had practically disappeared as a postoperative complication He observed that the incidence of this complication did not decline until the advent of antibiotics, though the mortality from it fell after the introduction, about 1930, of radiotherapy as a remedy Robinson held that the free use of antibiotics after operation probably accounted for its almost complete disappearance, and that better control of fluid and electrolyte balance and improved oral hygiene were minor factors He argued in favour of antibiotic prophylaxis, but foresaw the potential danger of this practice in a warning that antibiotic-resistant staphylococci might, in the future, give rise to a rebirth of the condition, and now Brown et al[3] have reported a twelvefold increase in the incidence of postoperative parotitis at the U S Naval Hospital, San Diego, California

The incidence rose from 2 in 171,826 operations in 1949–56 to 7 in 47,947 operations in 1956–57 Of the 7 affected patients 3 died, and parotitis was twice held partly responsible for death This serious complication was commoner in patients who had a stormy postoperative course, but it could be the only incident in an otherwise uneventful convalescence *Staphylococcus aureus* was isolated from the parotid gland in 5 of the 7 cases, in the other 2 patients the lesions were aborted by early treatment Unfortunately the antibiotic-sensitivity pattern of the staphylococci was not recorded Brown et al believe that this complication is likely to be related to the increasing number of carriers of antibiotic-resistant staphylococci in every hospital community In fact, however, they report that only 7 of 136 cultures of nasopharyngeal secretions from hospital workers yielded *Staph aureus*—a carriage-rate of only 5% (This is an astonishingly low figure, the rate is usually about 50%) But nasal carriage is by no means the only important factor in the spread of staphylococci in hospitals[4]

We have deplored the abuse of antibiotics in prophylaxis[5], and these substances have no part to play in the prevention of surgical parotitis It can only be hoped that this dangerous complication may be avoided by common sense attention to fluid balance and oral hygiene, and by energetic measures to restrict the spread of hospital staphylococci[4–6] Staphylococcal parotitis, once established, can progress so quickly that early diagnosis and treatment are essential An antibiotic to which the hospital staphylococcus will probably be sensitive—chloramphenicol, erythromycin, or novobiocin—should be administered, and, in the experience of Brown et al early radiotherapy is still of value If these measures fail to limit the infection, surgical drainage should be established without delay It remains to be seen whether parotitis is to become yet another manifestation of the staphylococcus plague[7]

RETINAL PHOTOGRAPHY

SKILLED ophthalmoscopy yields information not only about local conditions but also about general disorders But the technique is not easily mastered, and even an experienced ophthalmoscopist finds difficulty in describing his observations A short period in an ophthalmic department is enough to impress beginners with the differences between reports on a single fundus by a group of experts, and serial observations of a progressive fundus lesion, made in ignorance of previous records, show how open to error the method is Many progressive retinopathies, such as those associated with hypertension, diabetes, and suspected intracranial tumours, demand more accurate observation than is possible with ophthalmoscopy, and ophthalmologists are therefore turning to photography for objective records

The Zeiss-Nordenson retinal camera, introduced in 1915, depended for its light source initially on a carbon arc and later on a filament lamp

> An image of this source was formed by optical means at the margin of the dilated pupil and a cone of light entered the eye and illuminated an area of the retina An aerial image of the illuminated fundus was formed within the instrument by a powerful convex lens as in indirect ophthalmoscopy, and this aerial image was photographed by a built-in camera designed on the principles of a single-lens reflex camera

The Zeiss-Nordenson camera gave good monochromatic photographs of the retina with exposures of a tenth to a twenty-fifth of a second, but such long exposures were liable to cause failures due to blinking and ocular movements, and with colour photography (calling for exposures of a half to a fifth of a second) failures were even commoner Modern developments in lighting have led to successful colour photography with fast exposures[1-4] For this purpose a high-speed electronic discharge flash-lamp has been incorporated in the Zeiss-Nordenson camera, or this camera has been adapted to a xenon-arc lamp But there is a great demand for entirely new models, and Hansell[5] describes seven which have appeared in the last year or so Most are based on the Gullstrand ophthalmoscope and Zeiss-Nordenson camera

> Illumination for focusing is usually independent of that for photography In most, colour photographs can be taken by rapid exposure with an electronic flash One camera compensates not only for refractive errors including astigmatism but also for chromatic aberration in the human eye 35 mm film is standard, and most models have standard detachable camera bodies which may be interchanged with other instruments

Despite all this effort, retinal photographs, even in colour, leave much to be desired, and it remains more difficult to recognise a retinal condition from a photograph than from an artist's painting Admittedly this may be partly because the artist, like the ophthalmologist, has preconceived notions which bias his observations, but the artist can give a satisfying Mercator-like projection of the fundus which resembles the subjective impression on examining the retina It is difficult to imagine an optical device which could do this—or a suitable method of illumination In this respect modern retinal cameras are less satisfactory than the original Zeiss-Nordenson camera, for with them the photograph records a smaller area of fundus, and consequently a clinician who needs a record of, say, the whole length of a retinal blood-vessel, must take serial photographs and piece them together Some of Leishman's[6] excellent illustrations are composed of eleven separate photographs A further difficulty for the clinician wishing to use the retinal camera as a research tool concerns magnification The size of the retinal details depends not on refractive error but on the total refractive power of the eye For example, the optic disc will be smaller in a photograph of a large emmetropic eye than of a small emmetropic eye One type of camera makes certain compensations for refractive power, but this modification is intended to give constant size of field—not to compensate accurately for differences in refractive power No doubt in time these difficulties will be surmounted, but meanwhile we are a long way from achieving the perfect retinal camera

MEDICINE IN ASIA ORGANISATION AND EDUCATION

IN Europe there are about 930 people to every doctor, in Asia the corresponding figure is more than 6400, and in some parts of Asia it is higher still—e g , over 70,000 in Indonesia and over 174,000 in Nepal But medical services are expanding fast before the late war there was but a handful of health centres in all Asia, but at the end of last year there were 7251 multi-purpose centres, excluding those in Japan (about 900) and China As Dr John B Grant points out in a report to the Rockefeller Foundation, such swift expansion causes difficulties in organisation, and inquiries are needed into what administrative machinery should be provided Lack of such inquiries, he says, is leading to administrative chaos in several countries As the best solution to the problems of organisation, he suggests a regionalisation of services on the lines lately begun in Puerto Rico[1]

Even more important is the shortage of doctors and health workers, and the fact that the graduates of many of the present medical schools (and other training institutions) are not really competent to staff the new health centres—a situation necessitating hurried courses aimed at giving the graduates training in the work they will do The purpose of undergraduate medical education, as Dr Grant sees it, is

> "To train an undifferentiated physician, competent to undertake general practice in his own community A large part of general practice in Asian countries is to staff and administer peripheral health centers The undergraduate medical curriculum of these countries is patterned on curricula of the United States and of the United Kingdom and entirely unoriented towards the health care service demands of these Asian countries It is true that the quality of medical education should not in any way be endangered by service pressures However, undergraduate medical education unoriented towards local needs is not quality education in the true sense"

It will not be easy, he says, to provide such education, experiments must be made in the extension of training beyond the universities' own ward and outpatient services into the community The universities must control their own community agencies, such as health centres, where the medical clerk and the intern can have facilities to train themselves in what increasingly is becoming general practice in their community But this must await the establishment of accepted standards of service in these centres—as yet there are none

In some countries the necessary expansion and change is held up, not by lack of funds, but by conservatism in the faculty Dr Grant cites Calcutta, where none of the four medical schools has established a chair of social and preventive medicine, despite the Government's offer to pay the whole capital cost and half the running costs for five years The solution, he thinks, is for each country to use its *new* medical colleges to establish a progressive curriculum, to serve as an example to the others A successful demonstration is the best means of persuasion The All India Institute of Medical Sciences, founded two years ago in New Delhi, will, it is hoped, provide such a demonstration Moreover, each country needs an agency, representing the Ministries of Health and of Education, to plan medical education and serve as a liaison between the Government and the peripheral institutions Such an agency could disseminate new ideas and recommendations in medical education

Congresses

INTERNAL MEDICINE

The fifth congress of the International Society of Internal Medicine was held in Philadelphia on April 23–26, under the presidency of Dr T Grier Miller We publish below short accounts of some of the contributions to the congress

Medical Treatment of Hypertension

Prof R W Wilkins (Boston) claimed good results from medical treatment of hypertension in addition to rauwolfia, veratrum, hydrallazine, and ganglion-blocking agents, chlorothiazide was proving successful He regarded its chief use as that of a hypotensive drug, in combination with other agents Usually smaller doses could be employed he often started with 125 mg t d s, and found it unnecessary to exceed 750 mg daily Side-effects in 500 patients had included potassium depletion in nearly 40% (requiring replacement), nitrogen retention, sodium depletion, alkalosis, and collapse Potassium depletion was the most frequent and important, sometimes causing cardiac arrhythmias 5 deaths had occurred in patients receiving chlorothiazide, although it was impossible to be certain whether the drug was responsible The reason for its hypotensive action was unknown He also warned against the production of angina by hydrallazine due, to increased cardiac output, and by ganglion-blocking drugs due to poor coronary flow

Diet and Serum-cholesterol

Prof H Malmros (Lund) reported that the serum-cholesterol level could be lowered if ethyl linoleate was added to the diet, and butter fat was also excluded No lowering was seen if butter fat continued to be taken Milk fat and hydrogenated whale or coconut oil added to diet caused a rise in cholesterol Professor Malmros had treated patients with familial xanthomatosis over long periods with diets containing no milk or butter but with substitution of corn oil the cholesterol invariably fell He advocated this diet in coronary-artery disease

E C G Changes in Cardiac Infarction

Dr A Myasnikov (Moscow) reported that application of a piece of necrotic muscle to the normal heart in frogs and rabbits produced cardiographic changes of acute myocardial infarction These changes were due to the migration of potassium ions from necrotic muscle into adjacent zones, and it was suggested that the changes in cardiac infarction were derived from the zone surrounding infarction rather than from the damaged muscle itself

Anticoagulant Therapy

Dr J W Keyes (Detroit) emphasised that the maximum benefit of long-term anticoagulant therapy after cardiac infarction was seen in the first 18 months, after which the death-rates of treated and untreated groups became very similar, although the mortality remained higher in the untreated group If long-term anticoagulants were to be discontinued it was wise to wait until 18 months after an infarction He doubted whether patients receiving anticoagulants for rheumatic auricular fibrillation with emboli could ever safely discontinue therapy

Dr P E Lucomsky (Moscow) regarded anticoagulants as obligatory in all cases of myocardial infarction, and they should be continued for 6 weeks He also advised anticoagulants for severe and repeated angina

Dr M Wiener (New York City) said there was no particular advantage of any one hypoprothrombinæmic drug over any of the others, and the choice depended on whether a rapid, intermediate, or long-acting preparation was required

Dr T Astrup (Copenhagen) pointed out that anticoagulants in cases of cerebral thrombosis might carry a greater risk of hæmorrhage into the infarcted area; since he had found the meninges to possess greater fibrinolytic activity than any other tissue

Dr F Koller (Zürich) regarded the Quick one-stage prothrombin estimation as unsatisfactory, since it did not give a true indication of what was happening Factor IX could not be measured, but Stewart's factor could be and showed a discrepancy with the Quick test Stewart's factor more accurately reflected the tendency to hæmorrhage than prothrombin estimation, and may prove a more reliable guide

Dr S Cosgriff (New York) advised intermittent heparin whenever the prothrombin-time fell below the therapeutic range He also recommended oral vitamin K_1 if the prothrombin-time rose above 35 sec

Dr Irving Wright (New York) had found that thrombotic episodes were more common than expected following sudden cessation of therapy, and although statistical evidence was not available he had the impression that slow stoppage prevented thrombosis

Insulin and Dehydration

Dr J Roguski (Poznan) reported that small doses of insulin hastened rehydration in cellular dehydration caused by vomiting, but it might give rise to hypokalæmia Mental disturbance after drainage of ascites due to hepatic cirrhosis was usually the result of hypokalæmia with or without hyponatræmia, and a similar picture could occur after long-continued treatment of heart-failure with low-sodium diet and mercurial diuretics

Intracardiac Thrombi

Dr H Berg (Hamburg-Eppendorf) reported 4 cases of intracardiac thrombi diagnosed during life by auscultation over the carotid artery Murmurs developed under observation which were either rough systolic murmurs or vibrating murmurs which changed at different times and were often intermittent The 4 cases were proved at necropsy

17-Hydroxycorticosteroids and Liver Disease

Dr G Bossa (Naples) described estimations of 17-hydroxycorticosteroid levels in the blood of dogs and of patients with mitral stenosis and with hepatic cirrhosis He concluded that liver disease interfered with the normal breakdown of 17-hydroxycorticosteroids, but the blood-level in such patients was unusually low, probably the result of diminished glucocorticoid secretion by the adrenal cortex

Benign Orthostatic Albuminuria

Dr E Lowgren (Vasteras, Sweden) suggested, as a result of electrophoretic study of the blood and urine, a new mechanism for benign orthostatic albuminuria The constant electrophoretic pattern, resembling that of lymph, seemed to indicate that the albuminuria was due to post-tubular lymphuria and was not the result of glomerular infiltration

Corticotrophin as Diuretic

Dr M H Rigoli (Buenos Aires) reported the production of diuresis by intravenous corticotrophin in patients with acute tubular insufficiency, manifested as anuria or oliguria The diuresis always occurred within 24 hours and did not seem to be a coincidental spontaneous diuresis, since it was produced irrespective of the day of the disease on which corticotrophin was administered He could not explain his observations The dose used was 50 mg in 24 hours

Symposium on Hæmatology

Dr J S Richardson (London) said that leukæmia could be preceded by a state, occasionally lasting some months, which might present as aplastic anæmia, leucopenia, thrombocytopenia, or pancytopenia (hypersplenism). Occasionally macrocytic anæmia might be found. The bone-marrow did not at this stage suggest leukæmia, but some months later leukæmic cells appeared. The correct diagnosis might be suggested if an enlarging liver was encountered during the preleukæmic phase. It was tempting to believe that this condition had a multiple ætiology, but invariably progressed to leukæmia.

Dr LUIGI VILLA (Milan) reported differences in the physical properties of desoxypentosenucloid acids in the nuclei of normal and leukæmic cells. These differences appeared to be linked with the physical state of the D.N.A. molecules.

Dr M. ROMER (Caracas) had studied the red cells in iron-deficiency anæmia and concluded that microcytosis developed first, followed by hypochromia, and finally a fall in the number of total red cells.

Prof HISAO MORITA (Tokyo) reported that he had established the existence of 4 blood-groups in human platelets corresponding to the ABO system. He also described a method of measuring platelet fragility.

Dr CARL MOORE (St Louis) emphasised that normally only 10% of food iron was absorbed, but this may be doubled in iron-deficient subjects. Ascorbic acid considerably enhanced absorption. In men iron-deficiency anæmia theoretically would take about 6 years to develop on an iron-free diet in the absence of bleeding, but only very small amounts lost continually would cause anæmia.

Arthritis and Rheumatism

Dr R. L. BLACK (Bethesda) said that steroid therapy did not replace rest and physiotherapy, but when indicated should be used in the lowest possible dose. He had followed 59 patients with rheumatoid arthritis receiving prednisone for up to 3½ years. 8 patients died, 2 from fulminating infections and 2 from gastrointestinal hæmorrhage; the remaining 4 deaths may have been unrelated. 15 patients developed peptic ulcers, and higher doses seemed more likely to produce ulcers. 9 patients developed fractures, usually vertebral. Only 3 patients with serious complications received less than 15 mg daily. He believed that vascular lesions similar to polyarteritis nodosa were an integral part of rheumatoid arthritis, and could be found in patients who never received steroids.

Dr D. LONG (London) described experiments on guinea-pigs showing that thyroid activity was considerably increased if an antigen was injected into a hypersensitive animal. Thyroxine increased the severity of allergic reactions in guineapigs, and since these reacted similarly to monkeys and man, he speculated on the possibility of hyperthyroidism being the underlying basis for human hypersensitivity to streptococcal allergens. He pointed out that when thyroidectomy had been carried out in the past in patients with rheumatic fever, the symptoms had abated strikingly.

Prof NANNA SVARTZ (Stockholm) reported that a factor capable of agglutinating sensitised erythrocytes could be demonstrated in the serum of 85% of rheumatoid-arthritis patients. This factor was precipitable in the cold, but hæmagglutinins in other collagen disorders remained in the supernatant fluid. Ultracentrifugation established that this factor was present in fractions containing macroglobulins.

During a panel discussion Dr LONG thought that clinical trials comparing cortisone and aspirin were a waste of time, and urged research into their mode of action as a first step. He said that much of the earlier work on infection in animals receiving steroids was invalid owing to species difference, and there was little evidence of true anti-inflammatory effect apart from depression of delayed tuberculin sensitivity.

Dr SCULL advocated large doses of steroids, and he had found different patients responded better to different compounds. He did not believe there was any increase in intercurrent infection among patients on steroids. He recommended gold for ambulant patients on steroids initially, until an effect from gold was obtained, but he did not think there was any synergistic effect. He had found improvement in patients receiving chloraginine for rheumatoid arthritis.

Dr R. H. FREYBURG (New York) preferred not to exceed 15 mg of prednisone or equivalent daily in males and 10 mg in females. He has been disappointed with antimalarial drugs in rheumatoid arthritis. For acute gout he recommended colchicine, phenylbutazone, and steroids in that order of preference.

Stress and Cerebral Function

Dr LORING CHAPMAN (New York) found that patients with chronic diseases causing prolonged stress, such as peptic ulcer or ulcerative colitis, did not show any impairment of the highest integrative functions of the brain if there was no disturbance of behaviour or mood. In patients where there was such disturbance severe loss of higher functions was found.

Aphasia and Writing

Dr V. G. VON MUNDY (Knittelfeld) reported that aphasia as a result of hemiplegia in children who had not yet learned to write was slight and rapidly recoverable. He suggested that the unilateral development of the speech centre was related to the use of one hand for writing. Adults who were illiterate retained symmetrical speech centres, and in them aphasia was also slight or absent.

Obliterative Atherosclerosis

Dr K. GIBINSKI (Bytom, Poland) reported comparisons between venous blood obtained from the lower limbs of subjects with obliterative atherosclerosis and blood from upper limbs. No significant difference was found in content of proteins, lipoproteins, or cholesterol. Serum-glutamic-pyruvic-transaminase was higher in lower-limb blood, and there was a marked decrease in serum-proteolytic activity. There seemed to be some correlation between this decrease of proteolytic activity and the severity of the disease.

Lipids and Coagulation

Dr E. SZCZEKLIK (Warsaw) reported that the serum-prothrombin level, using Quick's one-stage method, and level of factor VII accompanied the rise of serum-cholesterol in early atherosclerosis, although the phospholipoids and C/P ratio remained normal. In later atherosclerosis an increase in C/P ratio occurred and in addition to increased prothrombin and factor-VII levels, there was delayed thrombin inactivation and protraction of fibrinolysis time.

Splenomegalies of Banti Type

Dr C. CRUZ LIMA (Rio de Janeiro) found that congestive changes with thromboses in the spleen, and reticular proliferation with endophlebitis in the liver could be produced in dogs by giving horse-serum for periods up to 5 months and inducing sensitivity. He considered the picture similar in many respects to Banti's syndrome in man, and suggested that hypersensitivity might be one cause.

Hæmoptysis in Older Men

Prof KATHERINE BOUCOT (Philadelphia) reported diagnostic and follow-up studies in a group of 395 men over 45 years who had hæmoptysis. In 43% no cause could be found, 33% had lower respiratory infections, 9% bronchial neoplasms, and in 9% the cause was cardiovascular. Only 18% who had hæmoptysis as an isolated symptom were found to have severe disease. She had not seen bronchial carcinoma in men who smoked for less than 20 years, and occasional smokers had to smoke for 40 years or more before developing a carcinoma.

Pretibial Myxœdema

Dr OTTO WEGELIUS (Helsingfors) reported 21 patients with pretibial myxœdema in association with exophthalmos. The peak incidence was between 40 and 60 years, and women greatly outnumbered men 15 patients had received previous treatment for thyrotoxicosis, and pretibial myxœdema might develop as long as 2 years afterwards As a result of animal experiments he attributed the condition to the action of thyrotrophic hormone upon the connective tissues of a hypothyroid subject in any area of slight dependent œdema—for instance, the lower legs and pretibial region

Ventriculography in Mitral Disease

Dr J F Uricchio (Philadelphia) described the results of left ventriculography in 42 patients with mitral-valve disease A needle was inserted directly beneath the xiphoid Patients with significant mitral incompetence showed considerable opacification of the left atrium, and this method enabled an accurate diagnosis to be made Arrhythmias and conduction defects arose at the time of injection in some patients there had been 2 deaths, 1 from cardiac arrest, and the other from direct injection into the myocardium

Depression of Serum Freezing-point

Dr E Olmstead (Milwaukee) described the value of the depression of the serum freezing-point in some clinical syndromes In normal persons this figure was very constant and required only 2 ml of plasma for its estimation Most of the depression was due to the plasma-sodium In overhydration the freezing-point was above normal, but it was lowered in primary water loss In salt depletion the value remained normal despite a low serum-sodium, and in primary renal impairment the freezing-point was lowered further, despite a low or normal serum-sodium This was probably the result of the retention of other metabolites

Radiation Nephritis

Dr R W Luxton (Manchester) discussed radiation nephritis in 53 patients who had had renal disease after abdominal irradiation Acute radiation nephritis may come on 8–12 months afterwards recovery could take place, although the kidneys were permanently small Malignant hypertension may develop during the acute stage and recovery could still take place It may also develop slowly up to 4 years later

Treatment of Nephrosis

Dr H C Goodman (Bethesda) reported results of steroid treatment of 34 patients with nephrotic syndrome There might be complete remission, complete remission with normal serum-proteins but residual albuminuria, partial remission, or none 40 mg of prednisolone or equivalent was given daily for a month A good response, when it followed, invariably did so within 10–14 days In the absence of a response, steroid withdrawal might sometimes cause diuresis Relapses were always followed by second remission with a further course of steroids In only 1 out of 7 patients did chloraquine seem to have any beneficial effect

Paroxysmal Ventricular Tachycardia

Dr G R Herrmann (Galveston, Texas) had analysed 175 consecutive cases of paroxysmal supraventricular tachycardia, and found approximately 75% to be associated with organic heart-disease, and a third showed partial auriculoventricular block, usually the result of digitalis Associated heart-disease was commoner in older patients and was usually ischæmic or hypertensive When tachycardia complicated recent infarction the prognosis was poor Tachycardia was poorly tolerated in presence of organic heart-disease, and he recommended rapid digitalisation, if none had been given previously It was also useful in preventing attacks There were no significant differences in rate between the groups

Hydrocortisone Metabolism in Hyperthyroidism and Myxœdema

Dr R E Peterson (Bethesda) reported studies on endogenous hydrocortisone in thyrotoxicosis and myxœdema Hydrocortisone was metabolised far quicker in thyrotoxicosis, and synthesis was more rapid The reverse was true in myxœdema These findings may depend upon an increase and decrease respectively of activity in the liver He suggested that severe myxœdema might be accompanied by a relative adrenal insufficiency

Symposium on Tuberculosis

At this symposium sponsored by the American Trudeau Society Dr R H Ebert (Cleveland) said that all antituberculous drugs, if given alone, led to resistance of organisms, and combined therapy over prolonged periods without interruption was to be preferred All drugs had toxic effects which had to be borne in mind About 50% of all patients destroyed isoniazid very quickly, but this was perhaps prevented by concomitant P A S Large doses of isoniazid in excess of 300 mg daily were now known to be tolerated safely if pyridoxin were given simultaneously He thought steroids had a definite place in the treatment of meningitis, combined with antibiotics

Dr Norman Wilson (Boston) said that the only indication for surgery was the failure or anticipated failure of medical treatment to control disease permanently Resection was indicated for destroyed units of lung or persistent caseation, particularly in inspissated cavities Thoracoplasty had a definite place in cases where there was extensive nodulation or fibrosis elsewhere in the lung, and especially in cases with open cavities and positive sputum, usually resistant to drugs Antibiotics had made possible less extensive thoracoplasties, and he advised a separate approach to each individual case

Carcinomatous Myoneuropathies

Sir Russell Brain (London) described 42 examples of carcinomatous myoneuropathy, of which 75% were associated with bronchial carcinoma Their appearance may antedate the detection of the primary tumour by up to 3 years, and although they often responded to its removal, this was by no means invariable Occasionally the syndrome developed after the primary growth had been removed There were varied syndromes, including cerebellar degeneration, sensory neuropathy, and involvement of pyramidal tracts and posterior columns Dementia could accompany these, and in a third of Sir Russell's cases a true myopathy alone was observed Pathologically, there was considerable degeneration of the affected area, with perivascular cuffing The exact mechanism was still unknown

Abacterial Subacute Endocarditis

Dr C Jiménez-Diaz (Madrid) said that abacterial subacute endocarditis presented a similar picture to the bacterial form, although the spleen was characteristically very large and the sedimentation-rate unusually high The plasma showed considerable hypergammaglobulinæmia, blood-cultures were always negative, and although histologically the lesions were identical with bacterial endocaroditis, postmortem cultures of the valves never showed bacteria He believed that the condition was not of bacterial origin, but the result of altered globulins converting the plasma into an autonoxious agent, and that rheumatic, Libman-Sacks, and other types of endocarditis might have a similar basis

Oral Hypoglycæmic Agents

Dr Charles Best (Toronto) said that at least two-thirds of diabetics who had had tolbutamide had continued to take this satisfactorily There was convincing evidence that oral hypoglycæmic drugs increased plasma-insulin and therefore increased pancreatic insulin production Sugar production by the liver was decreased In his department pancreatectomised dogs receiving tolbutamide constantly showed a rise in serum-alkaline-phosphatase and decrease in prothrombin The animals dying had all shown characteristic changes in the Kupfer cells

Symposium on Cardiovascular Surgery

Dr Alfred Blalock (Baltimore) reported that the survival-rate in dogs after ligating the descending branch of the left coronary artery was 30% in normals, but increased to 80% if omentopexy had been previously performed to increase collateral circulation. Experiments in dogs showed that the carotid artery transplanted into the myocardium remained patent in 90%, though the amount of fluid which could be perfused through it was very small. After this procedure the survival-rate following coronary ligation increased to 64%, but internal mammary ligation conferred no protection. He thought endarterectomy had a sound basis judged by necropsy experiments, since the perfusion-rate subsequently had much increased. He felt operation should be advised when pain continued and could not be controlled by medical means, and he used the Beck 1 operation, though the results were similar irrespective of the type of procedure.

Dr C. W. Lillehei (Minneapolis) said that open heart surgery now made it possible to deal with mitral and aortic incompetence. He emphasised that calcium was seldom found in the valves of mitral incompetence, nor was the annulus usually dilated, so that pathologically such valves were well suited for surgery. In such cases he repaired the valve by inserting ivalon strips beneath the cusps. Aortic incompetence could be repaired by inserting a new leaflet, and also a plastic valve beneath the coronary orifices. It was useless to employ open heart surgery unless the surgeon could work on the valve for at least 30–40 minutes, and consequently retrograde perfusion through the coronary sinus was used. Open surgery was suitable for mitral stenosis in cases with marked disability indicating gross valvular deformity in those with a history of emboli or with mitral incompetence or re-stenosis, and in all children.

Dr Robert Linton (Boston) said that indications for vascular grafts include obliterative arterial disease, aneurysms, arterial injury, tumour involvement of vessels, and congenital abnormalities. He did not now employ aortography because of increased risks, but he used arteriograms of limbs. He emphasised the successful use of end-to-end saphenous by-pass for localised obstruction in the lower limbs, which was the method of choice, and failing this he regarded thromboendarterectomy as a sound procedure. He did not use synthetic prostheses for replacement in the lower limbs owing to the risk of thrombosis, but he regarded this as very suitable for replacement of aortic lesions, followed by arterial homografts.

Medical Aspects of Cancer

For the first time in the history of the congress, a session was devoted to cancer. Prof Lowell Coggeshall (Chicago) mentioned that in America $30,000,000 was devoted annually to cancer research and to helping cancer sufferers. The internist could help at all stages—diagnosis, treatment and the management of the long-term patient. Mr E. Cuyler Hammond, SC.D. (New York), showed that the crude cancer-rate was increasing in all civilised countries. The abolition of other diseases augmented the rate, but did not explain the gross increase in carcinoma of the lung in men and in leukæmia in both sexes. Mortality from carcinoma of the rectum had fallen, probably due to earlier treatment, that of the stomach had fallen, but probably surgery had no part in this fall. The decline of gastric carcinoma was greater in the United States than in England. He quoted a survey in Connecticut which showed that the five-year survival-rate for cancer from 1935–40, 1941–6, 1947–51, was 19, 22, 25% for males and 29, 35, 38% for females. This rise was greatest for patients with growths of the rectum and colon, and for those with prostatic and uterine cancer. In the United States the present annual death-rate was 211,000 and it was estimated that this would rise to 322,000 in 2000 A.D., even if progress of treatment was maintained at the present rate. If coronary-artery thrombosis was abolished the cancer figure would be 566,000.

Prof E. Day (New York) concentrated his hopes of early diagnosis on periodic examination of available sites. A history of anæmia, loss of weight, or inertia and a family history might be precedents but the examination was all-important. He estimated that 28,800—i.e., 80% of the 36,000 who die yearly of rectal or colonic cancer—might be saved and that 10% of those who die of lung cancer might be saved by annual lung X-ray examinations, but he gave no figures to support these hopes. He was emphatic that digital rectal examination, never to be neglected, was inadequate; in 125 patients with carcinoma or with a carcinomatous polyp of the rectum, only 17 were detectable by digital examination, whereas the sigmoidoscope revealed all.

Dr D. C. Dahlin (Rochester) showed the value of cervical scrapes for diagnosing carcinoma of the cervix uteri. He was not in favour of similar investigations for carcinoma of the body, 90% of which caused post-menopausal bleeding and 80% of cases were amenable to surgery.

Prof R. H. Chamberlain (Philadelphia) and Dr Shields Warren (Boston) were modest in their claims for deep X-ray therapy and for isotopes. It was hoped that increased oxygen saturation of some tissues might increase the effectivity of radiation. Palliation was usually all that was obtained, and this was illustrated by the fact that no person with disseminated thyroid carcinoma had been cured. ^{32}P was very useful for polycythæmia vera but for leukæmia it was less effective than deep X rays. It was occasionally of value in plasma-celled myeloma causing bone pain.

Dr S. G. Taylor (Chicago) said the long-term survival patient often had inevitable pain, relieved by leading an active physical or mental life, by freedom from conflicts, by good nights' sleep. Simple non-narcotic analgesics helped at first but later there was no perfect drug. Narcotics combined with narcotic antagonists had failed to establish their claim. Addiction was uncommon. For many adrenalectomy and hypophysectomy added a few years of tolerable life.

Dr J. E. Eckenhoff (Philadelphia) discussed the relief of pain. Besides the standard measures, injection of the cœliac ganglion by the posterior approach was often effective for carcinoma of the pancreas. A preliminary injection of procaine, if helpful, was followed by an injection of 10% æquous phenol and gave benefit for 3–4 months. Injection of somatic nerves often helped incurable pain but produced neuritis in 20%. Finally, Dr A. M. Sutherland (New York) spoke of the psychological problems. Anxiety, fears, delusions, paranoic tendencies, and compulsive practices could all be helped. No word was said about smoking.

Poliomyelitis

Prof Jonas Salk (Pittsburgh) said that workers from many nations had contributed the foundation stones on which present progress depended. Killed vaccine with types 1, 2, and 3 virus produced antibody, and two doses given at short intervals produced a definite rise which was almost doubled by a third dose given seven months later. Although the titre fell, it remained slightly higher than it was before the injection of the third dose and remained so for 4 years. 0.1 ml. of vaccine intradermally further enhanced immunity and was a satisfactory antigen. A fourth dose was advisable as it helped approximately 10% who had not developed a satisfactory antibody level after three doses. At present he was not prepared to say dogmatically whether the value of vaccination lay in producing a hypersensitivity immune reaction.

Dr H. M. Gelfand (New Orleans) studied 157 families, each of whom had a neonate in it. Infection with poliomyelitis usually occurred very early, 70% being infected in 7 months and 90% in 30 months. Of 105 families affected, 33 had type 1, 35 type 2, and 37 types 3. Minor illnesses occurred but no paralysis. After two years, Salk vaccination was introduced and minor infections diminished. Virus excretion in the stools was less in the vaccinated. His experiments suggest that vaccination did not influence poliovirus dissemination.

Dr Hilary Koprowski (Philadelphia) described how the poliomyelitis virus had been attenuated by passage through insusceptible hosts. After 28 mice adaptations it was given orally to 3 children, having been proved non-pathogenic for monkeys Later it was given to many others, in two doses with a month's interval and later a third dose at 15 to 30 months' interval Passage through human individuals did not restore the pathogenicity as judged by injecting large doses into monkeys' brains It therefore appeared that a safe living vaccine devoid of pathogenic power but of rich antigenic capability was being developed

Symposium on Gastroenterology

Dr W L Palmer (Chicago) discussed exfoliative cytology in the diagnosis of cancer of the digestive tract Lavage material from 151 patients showed distinctive cells in 66 out of 69 with carcinoma, compared with 55 suggestive X-rays 2 with œsophagitis were misdiagnosed Among 871 examinations, 125 of 131 carcinomas of the stomach were diagnosed X-rays diagnosed 81 correctly, 27 as suspicious, and 23 as normal Cytological interpretation of material from the pancreatic and biliary ducts was difficult, but in 33 of 55 proven cases malignant cells were recovered 301 examinations were negative In 183 suspected cases of colonic carcinoma, 36 of 38 proved cases had malignant cells Barium enema showed carcinoma in 28, it was normal in 5 and questionable in 5

Dr C A Clarke and Dr R B McConnell (Liverpool) demonstrated how people with blood-group O in many parts of the world were more liable to suffer from duodenal ulcer No satisfactory reason could be given

Prof A C Frazer (Birmingham) discussed the differential diagnosis of steatorrhœa He emphasised the importance of a gluten-free diet in the treatment of patients intolerant of gluten, proof of intolerance was given by a relapse when gluten was given experimentally to patients previously on a gluten-free diet This treatment was preferable to steroid therapy, which had a use in emergency treatment

Cardiac and Vascular Diseases

Prof Robert L Levy (New York) compared a group of 50 cases of myocardial infarction treated with adequate anticoagulant therapy with a similar group receiving no anticoagulants There was a 17% error of diagnosis in both groups Mural thrombi, pulmonary emboli, and systemic emboli were equally common in both groups 3 patients in the treated group died of hæmorrhage The incidence of cardiac rupture in 557 cases from the literature and Professor Levy's personal experience was 4% in untreated and 12% in those treated with adequate anticoagulant therapy

Dr Stig Radner (Lund) described central aortic pressure curves and left atrial pressure curves obtained by needle puncture through the suprasternal notch During the Valsalva manœuvre and in fainting the aortic curve was characterised by a very sharp upstroke and a double notch on the downstroke Aortic stenosis was characterised by a slow upstroke on the aortic pulse and a presystolic peak in the left atrial pulse

Prof Isaac Starr (Philadelphia), in an appraisal of the ballistocardiogram, emphasised the need for rigidly standard conditions before assessing the amplitude of the main deflections The abnormal form of some ballistocardiographic tracings had been simulated by pressure injections into the great vessels in the cadaver

Dr John J Sayen, Mr W F Sheldon, and Mr George Pierce (Philadelphia) described the changes in the myocardium of dogs following ligation of a medium branch of a coronary artery In the affected area oxygen tension fell rapidly and muscle contraction became abnormal Breathing oxygen and infusing noradrenaline raised oxygen tension nearly to normal and improved contraction in the ischæmic muscle

Prof G E Burch and Dr Lawrence Golden (Tulane) recorded spatial vector cardiograms from 233 clinically normal subjects Distortion of the QRS vectors was seen when the conventional ECG was normal Such distortions became commoner with advancing age, rising from 22% in the third decade to 68% in the sixth decade

Prof Herbert L Ratcliffe and Mr Theodore G Yerasimides (Philadelphia) found an increasing incidence, in recent decades, of arteriosclerosis in birds and mammals at the Philadelphia Zoo This was not related to increased longevity nor to a higher dietary intake of fat Social pressure and group conflict among the animals were possibl explanations

Effect of Rubefacients

Dr F A Elliott (London) described changes in blood flow induced by rubefacient agents After the production of an intense cutaneous erythema of the thigh, the temperature of the feet rose in 17 out of 30 patients with arterial disease of the legs Effort tolerance was increased tenfold in some cases of angina after erythema of the chest wall had been induced, and a rise in cerebrospinal-fluid pressure was recorded in 9 out of 12 patients with cerebral infarction whose necks were made erythematous Atropine and sympathectomy abolished this effect A cholinergic efferent nerve pathway was postulated

Steroid Therapy for Psoriatic Arthritis

Dr J L Hollander (Philadelphia) and his colleagues had used the steroid triamcinolone (delta-9-alpha-fluoro-16-alpha hydroxyhydrocortisone) in psoriatic arthritis Of 17 patients on 8–16 mg daily, 11 showed almost complete healing of skin lesions Improvement in the arthritis resembled that produced by prednisone Cessation of triamcinolone therapy resulted in prompt return of psoriasis Side-effects of the drug, especially anorexia, were common

Pulmonary Hypertension

Dr D S Short (London) described 70 post mortem pulmonary ateriograms in controls and in cases of pulmonary hypertension Abnormal arteriograms were obtained in all cases of pulmonary hypertension, the changes being most striking in the smaller vessels Some vessels were completely obstructed and abnormal communicating vessels were then found There was a generalised diffuse narrowing of vessels of less than 1 mm diameter The narrowing was due to permanent muscular contracture, a hypersensitivity of the vessels to an initially raised pressure

Primary Biliary Cirrhosis

Dr Albert Snell (Palo Alto, California) said that both the nutritional state of the patient and the metabolic functions of the liver were well preserved until late in the course of primary biliary cirrhosis There was a characteristic biochemical defect, in which the serum lipids, bilirubin, and alkaline-phosphatase levels were raised The presence or absence of cutaneous xanthomas depended on the serum-lipid level Prolonged T-tube drainage of the bile passages might lower bilirubin and lipid levels and relieve pruritus, without conferring other benefit Continuous or intermittent therapy with adrenocortical steroids had helped some patients Preparations of linoleic acid (to lower serum-lipid levels) had been disappointing, though symptoms had sometimes been relieved

Uses of the Miller-Abbott Tube

Dr T E Machella (Philadelphia) discussed the uses of this tube in the diagnosis and treatment of gastrointestinal diseases They included the collection of œsophageal washings for examination for the presence of malignant cells, collection of duodenal juice for microscopic examination of bile, chemical analysis for the amount and concentration of pancreatic enzymes, and examination for the presence of exfoliated malignant cells, obturation of the duodenum as an aid to cholangiography, location of the site of intestinal bleeding, localisation of a point of partial intestinal obstruction, radiological display of small intestinal lesions, and the reproduction of distension types of pain at the suspected site of origin by air insufflation of a balloon In treatment, the tube could be used to deflate the bowel in ileus, to protect sutures in intestinal anastomoses, and as a " medical ileostomy " to prevent small intestinal contents from reaching the colon in patients with ulcerative colitis

SYRINGE SERVICE IN THE SMALL HOSPITAL

J. J. JUSTICE
M.B., B.Sc. Glasg., D.P.M.
MEDICAL SUPERINTENDENT

F. C. RALPH
A.I.M.L.T.
SENIOR TECHNOLOGIST

ST. MARY'S HOSPITAL, STANNINGTON, NORTHUMBERLAND

INCREASING importance is being attached to the setting up and functioning of syringe services in hospitals. Various methods have been described, but these have been suitable only for very large units or groups of hospitals. The large initial capital outlay and the high running costs might discourage small units from attempting to set up a service, so our experience over the past three years may be of interest to other hospitals of similar size.

EQUIPMENT

Ovens.—It is agreed that boiling is ineffective, and therefore hot-air sterilisation is obligatory. We use two ovens—a small one in the admission unit, and a larger one in the laboratory for the remainder of the hospital. They cost £40 and £160 respectively and are thermostatically controlled.

Containers.—We tried glass test-tubes with adhesive-tape sealing but abandoned them because of difficulties in unsealing and because breakages of both container and syringe were high. We found also that metal containers were not ideal: they took up a lot of space and rolled about, and their contents could not be seen. Material used for packing was apt to char at the necessary temperature, and sealing was difficult. We have now adopted 'Cellophane' envelopes (McCartney 1951) and consider this the ideal method. The envelopes are brittle after heating and should be allowed to cool for an hour before being touched.

Syringes are all glass with metal nozzle able to withstand sterilisation at 160°C in the hot-air oven, in the following sizes: 2 ml., 5 ml., and 10 ml.

Needles are stainless-steel hypodermic nos. 12 and 20, intradermal, and serum no. 1.

Cellophane envelopes in the following sizes: $7 \times 2^1/_2 \times {}^3/_4$ in. flap (syringes), $3^1/_4 \times 1 \times {}^3/_4$ in. flap (needles). The two expendable envelopes together cost 1·025*d*.

Miscellaneous.—Cellophane adhesive tape 1-in. rolls, suitable wire baskets and trays for the hot-air oven, lubricating solution (liquid paraffin levis *B.P.* 1 part, methylated ether 4 parts).

METHOD

The syringes are cleaned in the wards by washing in water to which a suitable cleanser has been added. 'Sterovol' is particularly suitable, especially where specimens of blood have to be taken, because it does not foam and, on drying, does not leave a film on the glass. Some other cleansing agents tend to cause a film, which is liable to hæmolyse the blood. We have obtained every cooperation from the wards because the advantages of this system have been so obvious.

Clean syringes are returned to the laboratory and placed on the shelf of a cooling hot-air oven, and this completes drying. The barrels and pistons are not interchangeable; when they are being dried off before sterilisation they are mounted in pairs on a special rack which we have designed with hollow pegs to hold the barrels and with Terry's clips mounted behind these pegs to hold the pistons. The syringes are then assembled, lubricated, and packed for sterilisation. Each batch is tested in the steriliser by means of a Browne's control tube, type 3, one tube being in each cageful of syringes. We have also tested occasional batches with cultures of *Bacillus subtilis*, a sporing bacillus. Batches of about 100 syringes are now taken and lubricated in the following manner: the piston is placed in a jar of lubricating solution up to a depth of $^1/_4$ in. and then inserted in the barrel, the piston being drawn up and down to ensure even distribution of the lubricant.

The syringes are now placed in the cellophane envelopes, and the flaps are sealed with cellophane tape, or by means of cellophane cement. The tape is cut in 3-in. lengths and stuck to the overside of the $^3/_4$-in. flap; this provides an overlap throughout and forms a complete seal.

The needles are packed in envelopes $3^1/_4 \times {}^3/_4$ in. and are protected by cellophane straws cut into suitable lengths. These are sealed in packets in the same way as the syringes. Occasionally three or more can be placed in one packet for use at electroconvulsion-therapy session with relaxants. The syringes are now placed upright in wire baskets, and the needles on suitable trays. The needles are examined each time for hooking and touched up (if necessary) on an Arkansas stone. If they are blunt they are collected and sent in batches for sharpening, which costs about 2*s.* a dozen.

Baskets and trays are placed in the hot-air oven, and the current is switched on. Sterilisation is achieved in the oven at 160°C for an hour.

The oven is allowed to cool completely before the syringes and needles are removed, when they can be handled and distributed safely.

The capacity of our present arrangements is probably 100 syringes a day, which is ample for our use. The admission unit is self-supporting. The staff are now competent to carry out the sterilisation after an initial period of instruction.

Complementary to the sterilising service has been the design and development of a piece of apparatus for freeing stuck pistons in the all-glass syringes used. No piece of apparatus at that time existed, and the idea and development has been solely the work of one of us (F. C. R.). It is designed on hydraulic principles and consists of a release adaptor similar to a double-ended Weinraud connection. On one side a small syringe is fitted and filled with water, and on the other side the stuck syringe. The pressure built up is sufficient to free any stuck syringe. This apparatus can be obtained from Messrs. Robert Whitelaw Ltd., Newcastle upon Tyne, at about 4*s.* each. Since it is so cheap it can be kept in the wards. In this hospital the problem of a stuck syringe no longer exists. Breakages averaged previously 20 a month and now rarely exceed 2 a month.

CONCLUSIONS AND SUMMARY

A simple and efficient syringe service suitable for the needs of a small hospital is described.

The capital outlay is small—certainly less than £200. There is no need for additional staff, and the running costs are low. The wastage through breakages and deterioration of equipment through repeated boiling in hard water is eliminated

The method can be applied also to sterilisation of other pieces of equipment—e g , forceps, scissors, and scalpels

Envelopes are obtainable from Clear View Ltd , Crouch Hall, London, N 8, 'Steroxol' cleaner from Messrs La Porte Chemicals, Luton, Beds , and the 'Klintex-Ralph' adaptor for releasing stuck syringes from Messrs Robert Whitelaw Ltd , Klintex House, Great North Road, Newcastle upon Tyne

POLIOMYELITIS VACCINATION

Medical Research Council Statement

LAST week the Medical Research Council issued the following statement about poliomyelitis vaccination

(1) The Medical Research Council have been asked by the Government to advise whether, in view of the present shortage of poliomyelitis vaccine, American or Canadian Salk vaccine which has satisfactorily passed safety tests and been licensed for issue in the country of origin should be made available for use in this country without first being subjected to the safety tests of the Medical Research Council

(2) The Council have made a full review of the current situation in the light of their responsibilities for safety testing poliomyelitis vaccine in this country They have given careful consideration to all the available evidence on the risks attending the use of the various poliomyelitis vaccines now being produced, on the risks in different circumstances of leaving a large number of children and others in special need of protection unvaccinated during the late spring and early summer months of this year, and to information on the amount of vaccine likely, under present arrangements, to become available for use in the next few months

(3) Three vaccines against poliomyelitis are available for consideration the British vaccine, imported American or Canadian vaccine that has passed British safety tests, and imported vaccine from the American or Canadian sources that has not been subjected to British safety tests The two former are now in use in this country the latter, at present, is not, although vaccine of this type has been used extensively elsewhere

(4) All poliomyelitis vaccine at present in use is made from three types of virus, types I, II and III In both the British and the American or Canadian vaccines, similar strains of the type II and type III viruses are used On the other hand, two different strains of type I virus are used The American and Canadian vaccines include the relatively virulent type I strain, known as Mahoney, the British vaccine, the much less virulent type I strain, known as Brunenders If, therefore, some of the virus failed to be inactivated in the course of manufacture, the British vaccine would be less likely to produce poliomyelitis on injection than would vaccines made from the Mahoney strain

It is the use of a type I strain of low virulence that makes the British vaccine the safest yet produced

(5) All vaccines are submitted to a series of safety tests at several stages before issue, both during and after manufacture, with the object of detecting any virus that has survived the process of inactivation Of necessity only samples of each batch of vaccine can be tested, and the possibility inevitably remains that in the untested part of the batch a few particles of live virus may still be present. It follows, therefore, that the greater the size and number of the samples tested, the smaller is the chance of any surviving virus remaining undetected and the greater the assurance that can be given regarding the safety of the vaccine

(6) If vaccine is submitted to an adequate number of safety tests of the full range now in use, there is little chance of contamination with live virus escaping detection If a few particles of live virus do escape, the effect on the safety of the vaccine will depend upon their virulence With the Brunenders strain of relatively low virulence used in the British vaccine, it is most improbable that any ill effects would follow inoculation, with the Mahoney strain, used in the American and Canadian vaccines, such a possibility could not be excluded with the same assurance

(7) It was because the more virulent Mahoney strain is used in the preparation of American and Canadian vaccine that the Medical Research Council, when recommending that vaccine should be imported from these countries to meet the shortage of poliomyelitis vaccine in the summer of 1957, linked that recommendation with the proviso that such vaccine should be submitted to further safety testing in this country in order to increase the safeguards against any particle of live virus of the virulent strain being present in the vaccine when issued

(8) Taking all these factors into account, the Medical Research Council believe that the three vaccines under consideration can be placed in the following order of safety

(*a*) Vaccine made according to the British formula that has successfully passed British safety tests,

(*b*) Imported vaccine from America and Canada that has successfully passed safety tests in the country of origin and also British safety tests,

(*c*) Imported vaccine from the same sources that has successfully passed safety tests and been licensed for issue in the country of origin

(9) After carefully weighing all the available evidence bearing on this complex problem, the Council are satisfied that the risk of producing paralytic poliomyelitis by injecting any one of these three vaccines is very slight and that a person inoculated with any one of them is substantially less likely to contract paralytic poliomyelitis than if he is left uninoculated. Nevertheless, no vaccine can be guaranteed to be wholly free from risk, and the preference should always be for the safest known vaccine

(10) The Council reaffirm their view that British type vaccine which has successfully passed British safety tests is the safest poliomyelitis vaccine known, that the only justifiable permanent policy is to use every endeavour to produce this in such quantities as to meet all the needs of this country, and that any policy which has recourse to less safe vaccines should, however slight the risk, only be regarded as temporary

Next in order of preference is imported vaccine that has passed successfully British safety tests as well as tests in the country of origin

Third is imported vaccine which, although it has successfully passed safety tests in the country of origin, has not been submitted to the further British tests carried out by the Medical Research Council in this country

(11) The present problem arises because supplies of British vaccine and imported vaccine that have passed British safety tests are together insufficient to meet requirements, and cannot become sufficient in time to present a substantial deficit during the summer months when the incidence of poliomyelitis may be expected to increase

(12) After carefully examining the present situation the Medical Research Council have concluded that, as it would appear to be impossible to overcome by any other means the deficit which will otherwise be inevitable during the summer months, it would be advisable as a temporary measure to issue American or Canadian vaccine which has not been submitted to British tests, provided that it has been tested and licensed for use in the country of origin

(13) *In proffering this opinion, however,* the Medical Research Council wish to stress their advice that the role of imported vaccine untested in this country should be limited to that of a temporary supplement to meet the present shortage At the same time every endeavour should be made to obtain the maximum possible supplies of British vaccine and imported vaccine which has satisfied both British tests and tests in the country of origin, so that, at the earliest possible moment, the need to use imported vaccine untested in this country will disappear The final aim should be to dispense with the need to use any vaccine containing the Mahoney strain

In England Now

A Running Commentary by Peripatetic Correspondents

THIS year the Royal Academy had the cooperation of the weather for the opening of its summer exhibition on May 2, and the blatantly bohemian and the firmly fashionable were able to make their improbable joint excursion to Burlington House without benefit of plastic mack or duffle coat. Turning to the pictures we found that the hanging committee had relaxed their policy of segregation and the moderns were no longer corralled in galleries VII and VIII There was as usual something for everyone, and the visitor could turn from Mr Merton's triptych of the *Countess of Dalkeith*—" Such a nice picture for her husband to have " as the kindly lady next to me said—to Mr Bratby's more turgid rendering of family life in *Nell and Jeremy Sandford* In gallery I the medical visitor will find *Lord Cohen of Birkenhead*, painted by Mr Harold Knight, sitting before a panelled background, alert and politely attentive, as he has sat in the chair at so many meetings In the same gallery hangs Mr B Fleetwood-Walker's portrait of *Professor Norman Capon*, kindly and quizzical, in muted scarlet academic gown with purple facings In gallery V it was pleasant to find a friend from the Medical Art Society, Dr Phoebus Tuttnauer's brilliantly coloured *Boats at Rest* lie on equally vivid orderly shingle Those with an eye for tomorrow as well as today will find in the architectural room drawings of the Middlesex Hospital Medical School and the new College of General Practitioners

* * *

The morning after my seven-year-old set the house on fire I arrived late at the hospital My hair was singed and the smoke had given me conjunctivitis, stomatitis, laryngitis, bronchitis, and the jitters The chief problem on my mind was how to ensure that the incident would not recur During the day's work I was offered all kinds of advice

A pædiatrician said that Johnny had obviously made a mistake, which was part of the natural process of growing up but personally I do not care to live so dangerously A physician (common-sense type) said that the Cautionary Tales and the story of Harriet and the Matches should be introduced, but these have long been part of the family's library A dermatologist said the boy should have his backside tanned, but Johnny's skin is exceptionally insensitive to physical violence Another physician (a born research-worker) said it showed an experimental mind which should be encouraged A patient, dependent and resentful, waited a long time to see me, and, to keep her quiet, was told the reason She said the boy should be shut away in a home—meaning that he would then be unable to delay her access to the doctor A psychiatrist who is analytically minded told me that the desire of a child to destroy his family by fire results from a deep-seated conflict requiring prolonged psychiatric treatment It had not occurred to me before that Johnny's fire might have been smaller rather than bigger than he intended, but after a moment's thought I dismissed the idea as ridiculous An administrator thought that a list should be made of all items destroyed and their cost deducted from pocket money I worked out that Johnny would still be paying when he comes of age A surgeon suggested that the boy himself should assist in the radical operation necessary to clear the affected area

When, full of thoughts, I returned home, my three-year-old daughter said " Johnny is naughty He lit a bonfire in the house He is very sorry " I think she was right On the hall table was a parcel addressed to me and untidily wrapped in newspaper Its label said THIS IS MY SEECRIT STOR YOU CAN HAV IT LOVE FROM JOHNNY Inside were nine boxes of matches

* * *

Now that cautionary cards, long familiar to diabetics, are to be carried by patients who are having long-term anticoagulant therapy, I think it is time that I put into effect an idea which has been in my mind for many years My card or disc, which I shall always wear under my clothes, will read as follows

> I am a doctor If found ill or unconscious do not call in any of the doctors or take me to any of the hospitals whose names are on the reverse side of the disc

It will be such fun having the names engraved.

* * *

We medical students are sometimes more familiar with current theoretical speculations than with current practical treatment in the wards Take tab nihil for example Theoretically nihil is a pure placebo containing nothing except milk sugar, but in the wards it is quite effective therapeutically

Patients complaining of severe headache are given it with the advice " Here is something extra strong for you—just take half a tablet, on no account more!" The next day the doctor asks about the headache and is told that it has completely subsided, the patient has never felt better in his life, he has never had a better treatment, has never met a cleverer doctor

My preliminary investigation of this phenomenon shows that, because of their supposed superpotency, the tablets are in fact rarely if ever taken by the patient He feels a little uneasy about this and, to avoid further trouble with his conscience, tries to persuade the doctor that the tablets had such a splendid effect that no further treatment is necessary My next step is going to be a redouble blind check One group of patients will be given therapeutically active tablets and told they are a placebo, while the controls will get a placebo which they are told is therapeutically active, a second control group will get a placebo which they are told is a placebo Indeed, one of these days I am going to put myself on a course of *normal* saline injections to cure my chain-smoking In our wards normal saline has repeatedly been proved almost as effective as lobeline and it has no side-effects

* * *

In the following correspondence the italics are mine

Dear Dr X, I wonder whether you would admit this patient to your psychiatric rehabilitation centre He is shortly to be discharged from prison after a long sentence for larceny I enclose a copy of his clinical record

Dear Dr Y, Thank you for your letter Although the clinical record of your patient suggests that he is suitable for psychiatric rehabilitation, I regret that we cannot accept him as we only take patients whose behaviour is *antisocial*

Dear Dr X, Thank you for your letter Perhaps you will reconsider your decision when you know more details of the patient's social history He is aged 38 and has served 23 prison sentences, thereby, in his own words, doing " fifteen years' service " His usual practice is to obtain a job *in a hotel*, usually as a kitchen porter He then helps himself to anything he can find He has also in the past been convicted of vagrancy, dangerous driving, being drunk and disorderly, obstructing the police in the course of their duty, causing wilful damage to both public and private property, and of assault Personally I regard him as antisocial I do hope you agree

Dear Dr Y, I regret that I cannot alter my decision about this patient, as we only take patients who are *truly antisocial*

I am hoping to discover whether the words " truly " and " antisocial " have a technical meaning or whether they are psychiatric jargon for full beds

* * *

I once knew a scientist who was prouder of a rejection slip from *Punch* than of all his erudite scientific papers For myself, fame and pride knocked on the door when I became a peripatetic correspondent for the first time. Beside that all my papers on the metabolism of 5, 6, 7-hydroxycholesterol paled into insignificance I was so proud that I showed it to my boss He hasn't spoken to me since I found out later that he became a peripatetic the same day He says he knows the editor I wonder if

* * *

No wonder your correspondent didn't get very far with his one-spur idea I tried it once and the horse went in circles

Letters to the Editor

DEATH OF A BOXER

SIR,—In your issue of April 26 you mention an inquest on a boxer who died after lying in a semicoma for 321 days following a contest

From time immemorial the student of medicine has been taught to look seriously on the most trivial head injury Have his teachers ever made any serious attempt to inform the public how much permanent damage to the brain can and does follow the minor injuries which are normal and inevitable in boxing?

TREATMENT OF ASTHMA AND HAYFEVER BY HYPNOSIS

SIR,—The importance of clarifying the commonly recognised relationship between psychogenic factors and the clinical manifestations of allergic disorders makes it desirable to submit to critical analysis the report by Dr Mason and Dr Black (April 26) on the abolition of allergic skin-test responses in a patient under treatment of asthma and hayfever by deep hypnosis

They report a progressive loss of skin sensitivity to pollen allergens on the left arm of a patient undergoing weekly hypnosis and skin tests Occasional tests on the left leg, however, continued to give positive reactions, except on one single occasion when the patient was tested on the left leg immediately on waking from a deep hypnotic trance, during which it was suggested to her that there would be no reaction to tests anywhere on the body This loss of skin-test reactivity and the clinical improvement were attributed to the psychogenic effect of the hypnosis

There are, however, alternative explanations for the loss of skin-test reactivity The decreased and then negative reactions on the left arm may have been induced by the repeated vigorous skin testing (10 pricks were made into each site compared with the one prick commonly used for diagnosis) This phenomenon of local loss of sensitivity is not unfamiliar and may be due to local allergic desensitisation to which could be added temporary local loss of skin reactivity due to previous wealing reactions

The inhibition by hypnotic suggestion of a single test on the left leg, performed immediately on waking from a deep hypnotic trance, could be attributed to the well-known modification of peripheral circulation by hypnosis It is a common experience to find that patients who feel even slightly faint during testing, or whose skin is cold, fail to react to skin tests which excite vigorous reactions at other times The wealing responses of the allergic type are acutely dependent upon peripheral blood-flow, which determines the amount of exudation of serum from capillaries rendered permeable by the products of the allergic reaction

The claim by Dr Mason and Dr Black to have produced clinical improvement as well as the skin-test effects by hypnosis may have an alternative explanation

I have had under continued observation for the past 6 years a woman patient nearing 40 years of age who has a long history of severe seasonal asthma On three occasions she has been admitted to hospital in severe status asthmaticus Attempts at "desensitisation" with pollen extracts were marred by reactions due to her extreme degree of hypersensitivity She was instructed to treat herself during the spring and summer of 1956 and 1957 by making a single prick on her arm daily through a drop of 'Pollaccine' (100,000 units per ml) The summers of 1956 and 1957 have been as free of symptoms as the case described by Dr Mason and Dr Black This form of co-seasonal treatment by prick methods is used by many workers to supplement or replace pre-seasonal treatment. Dr Mason and Dr Black's patient could be said to have had such treatment by the vigorous weekly prick tests over a period of 10 weeks

Whilst one would not doubt that psychological treatment may benefit individual patients, the description of individual case-histories can readily be matched, as seen above, from patients treated by either psychological or allergic methods Convincing evidence must in this day and age rest upon carefully controlled trials of adequate numbers of patients A trial of this nature into the specific treatment of pollen asthma by pollen extract injection has shown that more than 80% of pollen asthmatics *derive considerable benefit from this treatment*[1]

Similar well-planned investigations are required for the assessment of psychological methods of treatment in allergic disorders

J PEPYS

SIR,—It is delightful, and to me at least *not* at all surprising, to get such an excellent and well-controlled *demonstration* (by *Dr Mason and Dr Black* in their paper of April 26) that the workings of the mind and nervous *mechanism* of the body are a necessary factor in the production of hayfever and asthma, and also of the modified and localised forms thereof produced by skin testing with the suitable allergen It is also reassuring to read that this nervous mechanism is only *one* of the necessary factors for their production the Prausnitz transference-of-serum phenomenon remained unaltered

The comparative failure of sedative pills is again satisfactory to the pathologist, for it is a blunderbuss and not a radical treatment They are a great saving of time and trouble for the practitioner, but the patient detects this about as quickly *as he does* and makes the obvious *comments to his* friends

The account of the attempt at desensitisation by injection of pollen extracts is hard to follow on the essential points of dosage, timing, &c, but it sounds as if it has been inadequate

Though the experiments were so satisfying as a demonstration, yet as a routine treatment for, *let us say, 100 chance* hay fever subjects I should think a properly conducted desensitisation course would have the advantage both in producing equally satisfactory results and of causing a *minimal* interference with the daily life of the patient

The personal relationship between patient and doctor is always of the greatest importance, and I suspect *that if* doubts and fears creep into the minds of the *hypnotic* expert and he allows his patients to know of this, *he is* courting failure That is certainly true of a desensitisation course if, at any given point in the course of injections, the practitioner fears a reaction, and by his *demeanour* lets the patient know of this, then reactions he will most assuredly get with all his more suggestible patients The importance of the relationship between patient and doctor is somewhat forgotten *nowadays* by *modern* "medical science"

GONADAL DYSGENESIS

SIR,—Dr Ferguson-Smith (May 3) is to be congratulated on his enterprise in determining the nuclear sex of 325 male patients in a mental-deficiency hospital He will undoubtedly be followed in his rewarding ætiological foray by a host of chromatographers, endocrinologists, and biochemists He cannot be equally congratulated on his choice of the words "primary microrchidism" to describe his 4 patients with gonadal dysgenesis It is quite true that it is not yet possible to give an exact ætiological description of such cases, but to describe their condition as "microrchidism"—unpronounceable word for the Sassenach—is to relate no more than our grandfathers knew.

The testicular appearances described and the conclusions which Dr Ferguson-Smith draws from his cases have already reached the textbooks [1]

Lawson Wilkins uses the group-term, *gonadal dysgenesis*, and the two types of testicular disorder described by Dr Ferguson-Smith he names "tubular germinal aplasia" and "tubular fibrosis" He recognises that these disorders have a varying pathogenesis The primitive gonad has a *cortex* (germinal epithelium), from which the germ cells are derived, and a *medulla* (mesonephros) from which the tubules and the interstitial cells are developed. He suggests that the defective development of the cortex results in germinal aplasia, while hyaline or fibrotic changes in the tubules may derive either from a defect in development of the medulla or from subsequent regressive changes

We may wait some time for a more exact knowledge of pathogenesis, but we have already a sensible descriptive nomenclature based on rational ætiological ideas

ATHEROSCLEROSIS AND ITS CEREBRAL COMPLICATIONS IN THE SOUTH AFRICAN BANTU

SIR,—In their stimulating article [2] on this subject, Dr Laurie and Dr Woods make some statements in connection with my findings in atherosclerosis in the Bantu which, in view of the considerable attention this article has attracted, cannot go unchallenged

They state that "In 3000 consecutive necropsies on Bantu in South Africa, Becker (1946) [3] found only 1 cerebral catastrophe, whereas in just under 2000 consecutive necropsies we have found 31 such patients—a prevalence almost fifty times greater than that in Becker's series" This is not correct In my series of 3000 consecutive autopsies, I reported 68 cerebral catastrophes, an overall incidence of 2 3% [4]

The causes of cerebral apoplexy (hæmorrhage and thrombosis) were as follows

	No of cases
Hypertensive arteriosclerosis	33 (*49%*)
Atheromatosis	1 (*1%*)
Congenital aneurysm	7 (*10%*)
Cardiovascular syphilis	2 (*3%*)
Embolism from endocarditis and rheumatic heart-disease	25 (*35%*)

The case ascribed to atheromatosis was one in which it was considered that this condition was the sole cause of the apoplexy; whereas in the cases of hypertensive arteriosclerosis, although atheromatosis was present in 64% of the cases, and in patients over 40 was present in nearly 100%,[3] I considered the hypertensive condition more important in the pathogenesis of the cerebral complication than the atheroma If on the other hand it is assumed, as Laurie and Woods have done, that the major factor in the production of cerebral thrombosis and hæmorrhage is atheromatosis, then the incidence of cerebral catastrophe in my series would rise to about 1% of all necropsy cases, which is comparable with Laurie and Wood's figure of 31 cases in 2000 autopsies (1 5%) In our last 144 consecutive necropsies on Bantu subjects there were 3 cases of cerebral vascular accident (2%)—a small series but perhaps sufficient to show that the incidence of these lesions in the Bantu lies somewhere between 1 and 2%

Laurie and Woods further state that I "found severe atherosclerosis in 26% of Bantu patients over 45, but only in 0 4% of the whole series was atherosclerosis the cause of death" They find a "significant discrepancy" between these two figures which they cannot explain. My definition of severe lesions at that time was "many lesions, together with complications such as dilatation, deformity, calcification, ulceration and thrombosis" I detailed 11 cases in which I considered the cause of death was due solely and entirely to atheromatosis, and clearly stated that it was difficult to assess how far atheroma contributed to the fatal outcome of disease of the cardiovascular system when it was associated with other cardiovascular diseases Of 137 cases which were classed as severe atheroma, 35% died a cardiac death, but many of these cases had evidence of hypertension as well The so-called discrepancy resolves itself into different points of view

Finally, I should like to stress that on occasion the Bantu can and does develop just as much atherosclerosis as the European in this country There is no inherent racial immunity to the disease I believe that the incidence of serious complications in the Bantu, particularly coronary occlusive disease, is significantly lower

THE DOCTOR'S ATTITUDE TO HIS PATIENT

SIR,—From the sidelines I have followed this correspondence with growing interest.

My attention was first directed to the subject by Dr Balint's two papers in 1954 [1] and 1955,[2] which whetted my appetite for a careful study of his book.[3] The papers by Dr Clyne [4] and Dr Pasmore [5] were obviously direct results of Dr Balint's teaching and showed that a prophet is not necessarily without honour in his own (or adopted) country

Whilst it would be too much to ask for a universal acceptance of psychoanalytic teaching, it had not seemed to me that Balint, Clyne, Hopkins,[6] and Pasmore had put forward any particularly controversial views they had merely stated facts and observations that any practitioner could confirm for himself if he cared to listen to his patients—though he may have to learn to listen But evidently I was wrong The subject is extremely controversial—and highly charged—and I have no doubt that Dr Balint could give a ready interpretation of the resistances shown

Yet it passes all understanding that anyone should put forward—let alone swallow—the proposition of "Scanner" [7] that "the emotional history should not have any direct influence on the doctor's clinical opinion" That the clinician may reach that opinion "without the emotional history" is no doubt often true; but to say that he "can give just as good advice and get just as good a result without ever hearing it" seems to deny many of the tenets of good medicine, from Hippocrates to Osler and beyond

---

[5] Pasmore, H. S *ibid* March 8 1958, p 524

[6] Hopkins, P *ibid* 1956, ii 455

[7] *ibid* April 12, 1958, p 800

Having decided that his patient is not suffering from tuberculosis, thyrotoxicosis, or severe heart-disease, but has an anxiety reaction (a not unusual condition) how would "Scanner" proceed with his treatment without ever hearing the emotional history, or could he in fact avoid hearing it? Or would his patient then be left to "recover, remain neurotic or become psychoneurotic"? What is the distinction between neurotic and psychoneurotic?

Dr Clyne's and Dr Pasmore's sails will not be sunk by a damp squib "Scanner" will need a gun of far greater calibre, even though he has Dr Lee [8] and Dr Ryle [9] to play Athos and Porthos to his Aramis

A scanner is presumably one who scans, which though defined as one who looks at closely or scrutinises is also used as meaning one who "glances at quickly, considers hastily" [10]

TOXÆMIA OF PREGNANCY

SIR,—My old friend and fellow student Mr Sophian (April 26) and I agree far more than we differ for he has accepted in toto my main thesis, which was regarded as revolutionary when it was first published a quarter of a century ago—that eclampsia results from a disturbance in *la fixité du milieu interieur* He believes that this disturbance is invariably caused by renal cortical ischæmia provoked by a uterorenal reflex

I do not accord the kidneys so exalted a position as he does, for I believe them to be but handmaidens to the hypothalamus and subject to nervous and hormonal control, both direct from the posterior pituitary and indirectly through the anterior pituitary and adrenal glands They must obey to the limits of their structural ability, and are often hampered by mechanical factors The only objection to his simple theoretical schema is that it does not work in practice, for hypertension, proteinuria, and œdema can occur independently of each other and in different sequences, while eclampsia occurs apart from any of these three signs

I very much appreciate Mr Sophian's generous remarks about my operation for denervating the internal iliac vessels As he knows, I have been interested in the effects of afferent nervous stimuli on renal secretion since 1934 [11] and agree with him that impulses from the uterus can affect the secretion of urine, cause pallor, sweating, vomiting, a profound fall in blood-pressure, bradycardia, and acute dilatation of the pupils, and initiate the onset of labour I merely feel that there is no justification for postulating a unique uterorenal reflex when similar effects on the kidney can be caused by afferent stimuli from other parts of the body

I wonder whether Mr Sophian would be so very kind as to give direct answers to the following three questions

(1) Infants, non-pregnant women, and men die from renal cortical necrosis If toxæmia of pregnancy results from cortical ischæmia why is eclampsia peculiar to the pregnant state?

(2) If resistance to uterine stretch is the stimulus which provokes renal ischæmia how is it that bilateral renal cortical necrosis practically never occurs in primigravidæ but is most likely to occur in association with toxæmic accidental hæmorrhage in a single pregnancy at about the seventh month in a woman who has previously borne 4 or more full-term children without toxæmic symptoms?

(3) How is it that patients with true eclampsia may secrete urine freely?

"Algebraic pebbles" together with the cooperation of the local health authorities, general practitioners, and hospital staff have reduced the incidence of eclampsia in Bradford, from 3 8 to 0 2 per 1000, and the number of cases of hypertension plus proteinuria by half, over a period of ten years The Medical Research Council have advised the Government that in their view there is a strong probability that cigarette smoking provokes carcinoma of the lung I submit that these figures from Bradford together with those from Siam, Hong Kong, Ceylon, and the Fiji Islands, provide a much stronger case for the thesis that eclampsia is to be attributed to imperfect nutrition together with the disadvantageous mechanical factors associated with pregnancy and the upright position

Bradford

G W THEOBALD

INFANTILE GASTROENTERITIS

SIR,—I am afraid Dr Sangster (April 26) has again begged the question of the essential place of *Escherichia coli* in this disease

All the references (1–5) he gives relate to work prior to 1948, when *Esch coli neapolitanum* was isolated by Bray Apart from serotyping, I have yet to see any new fundamental work stemming from this time

Cow's milk cannot be the whole answer, for the disease occurs in breast-fed infants as well, especially in maternity units

It is true that intestinal organisms enter by the mouth, but bottle-fed and breast-fed infants do not feed themselves or prepare their food The question of adult human carriers is surely, therefore, of paramount importance

I cannot accept that with present-day techniques the problem of isolating a virus, if any, is insuperable The question of serotyping is merely a refinement which does not invalidate the initial premise

Even the eminent source of the Royal College of Physicians of Edinburgh publication, to which Dr Sangster referred, failed to produce any adequate evidence to enlighten our essential ignorance of this intriguing condition

Ilford Isolation Hospital,
Chadwell Heath, Romford, Essex

I M LIBRACH

EFFECT OF HEAT ON SPASTICITY OF DISSEMINATED SCLEROSIS

SIR,—I read with great interest Dr Lyburn's letter of March 15 I agree with him that in multiple sclerosis the weakness and spasticity are greater in warm weather, and that the patients feel better when it is cool—a mild spring or autumn being their best time This is in keeping with the fact that excessive movement or massage or permanent confinement to bed is bad for these patients

Thrombi in the small veins of the central nervous system may be found, according to my observations, in as many as 90% of cases But I believe they should be regarded as a manifestation of an allergic process My histological findings in 20 cases of multiple sclerosis [1] seem to correspond fully with the well-known histological picture of neuroallergy as induced in animals or found in man

(1) hyaline degeneration and fibrous "delamination" of the vascular wall, (2) œdema and swelling of the endothelial cells,

UNILATERAL RENAL INJURY DUE TO TRANSLUMBAR AORTOGRAPHY

SIR,—The conclusion drawn in Mr Clark's article (April 12) merits further consideration

A large quantity of dye was injected, using a mechanical pressure apparatus, directly into the right renal artery In a recent survey McAfee[1] concluded that the risk of injury to the kidneys depends on the amount of contrast medium reaching them, the instance of complications being trebled if more than 40 ml of dye was used. The risk of renal damage cannot be entirely eliminated but can be considerably reduced if no more than 25 ml of contrast medium is manually injected after a small pilot injection is made to localise the needle site with reference to the renal artery

The new contrast media 'Urografin' and 'Hypaque' may prove less toxic than 'Diaginol' Furthermore, Mr Clark gives no evidence to show that the right kidney functioned normally before aortography, urine analysis after the examination showed no abnormal constituents which may have been expected if renal damage had occurred during the examination.

AUDREY COUCH
RAYMOND W GALLOWAY

CIGARETTE-SMOKING AND DISEASE

SIR,—The rising mortality from lung cancer and coronary thrombosis in older men is rightly described as a smudge on the picture of health in Scotland (April 12, p 789) Need one look far for the responsible "morbid process"? Surely not there is enough evidence for a prima-facie case against cigarette-smoking This addiction is probably also a big factor in Scotland's high morbidity (and mortality) rate from bronchitis

This report from Scotland should re-emphasise the great need for adequate anti-smoking education. Lung cancer (only one of the lethal complications of smoking) is killing nearly four times as many people as tuberculosis, but there is no corresponding official campaign of prevention. On the contrary, the barrage of tobacco advertising is permitted to continue unchecked, even when it is clearly aimed at adolescents Political fears about loss of revenue from tobacco taxation are always being emphasised, but what of the decimation of the male smoking population, what of the dollars spent on tobacco, and what of the fires and pit accidents caused by smokers? There are two views to be taken of the financial situation, and Dr Hugh Dalton did well to remind the House of Commons of this last week.

But there is only one reasonable view of the medical situation and it is high time the public was bluntly and decisively warned of the dangers There has been too much medical circumlocution already the use of such terms as "an association", "a link", "a connection", and even "a cause-and-effect relationship" between cigarette-smoking and lung cancer is too vague The public still thinks there is some reasonable doubt about it all. There is not, of course, and we should be honest and say "Most cases of lung cancer are the result of years of cigarette-smoking"

Dr Beynon (April 12, p 795) could do a considerable service by advising all *smokers* over 35 years of age in his area to have a twice-yearly chest radiograph Directly, he would find early cases of lung cancer, indirectly, he would educate the public in one of the dangers of this expensive and harmful form of self-indulgence He might even provide Mr Stocker (April 12, p 797) with some valuable experimental information

Leicester

J P ANDERSON

THIRST

SIR,—Your annotation on thirst (April 19) seems to confuse measurement of true osmotic values across semi-permeable membranes with an estimate of it obtained indirectly by determining the concentration of solute particles in a solvent—e g, by estimating freezing-point depression

Where a solution contains both diffusible and non-diffusible particles these two methods are bound to give different results Since we have this condition in biological materials, measurement of freezing-point depression is not a valid method for determining osmotic-pressure differences unless allowance can be made for the concentration of diffusible particles Since urea is believed to be distributed freely through total-body-water it cannot produce an osmotic gradient within the body If the cells of a "thirst centre" respond to changes in osmotic pressure they could not be expected to be influenced by changes in concentration of urea

The exceedingly complex permeability of cell membranes to different molecules and ions makes measurement of the real osmotic gradient in biological material very difficult Since we cannot readily produce artificial membranes whose permeabilities correspond to those of cell membranes and since the indirect methods of measuring osmotic pressure by freezing point depression and boiling-point elevation are not valid, one has usually to be content with a very crude reproduction of the cell membrane and with measurement of the osmotic gradient across it Perusal of the literature on osmotic pressure of biological systems makes it obvious that much confusion of thought exists and too often the writers fail to distinguish between the osmotic gradient and the value of the total osmotic pressure based on a method which really measures total concentration of solute particles

I am also rather astonished that your annotation should state that pure salt depletion can give rise to a sensation of thirst. It is usually considered that thirst is minimal or absent in pure salt depletion

Glasgow Royal Infirmary

JAS C EATON

⁂ Dr Eaton is referring to the difference between, on the one hand, the osmotic pressure of a solution, which, like the freezing-point and the vapour pressure, depends on the concentration of solute particles, and, on the other hand, the "effective" osmotic pressure, representing the osmotic gradient across the cell membrane

It seems very doubtful whether an osmotic gradient is maintained across all membranes a difference of osmotic pressure is probably rapidly abolished by a movement of water across the membrane.

The different effects of urea and sodium are probably to be explained by the different permeability of cell membranes to these substances, an increase in the concentration of urea does not affect the water content of cells, but an increase in the concentration of sodium (limited to the extracellular fluid) causes the cells to shrink.

---

[1] McAfee, J G *Radiology* 1957, 68, 825

While it seems paradoxical that sodium deficiency should produce thirst, it nevertheless seems to do so,[1,2] if thirst is defined as a desire for water —Ed L

NEW METHOD OF PHENOBARBITONE ADMINISTRATION

Sir,—I find it difficult to understand the letters written by Dr Pearson (April 19) and Dr Penman (March 29) Dr Penman states in his opening sentence that "no conclusion whatever can be drawn from the data presented by Dr O'Connor last week" Dr Pearson writes that "I cannot agree that Dr O'Connor has really demonstrated anything"

It appears to me that Dr O'Connor has demonstrated that when he treated 18 cases of epilepsy with the long-acting phenobarbitone 'Spansules', he virtually cured all the patients he treated On re-reading Dr O'Connor's article, I agree that it is open to criticism in many ways Nevertheless, if we are to believe what he has written, he has shown that with this long-acting phenobarbitone therapy a method has been suggested which may be of great value in the treatment of epilepsy His work may have been uncontrolled, but he has still demonstrated, even if only as a clinical observation, that all the cases he treated improved to such an extent that the results are really striking These results surely should not be ignored, even though he cannot explain them satisfactorily Dr O'Connor has produced enough evidence to stimulate a trial of delayed-absorption phenobarbitone in epilepsy by others

London, N W 3 H N Levitt

INDIRECT BILIRUBINÆMIA

Sir,—In your issue of April 19, Dr Schmid and his colleagues comment on our recent report dealing with the reduction of indirect bilirubinæmia They state that they have not been able to duplicate our results, they suggest that we may be doing harm by driving bilirubin from the blood to the tissues, increasing the risk of brain damage, and they urge all to desist from this therapy until further pharmacodynamic studies of glucuronic acid are carried out

It goes without saying that all new drugs should be thoroughly tested before clinical use and that they should not be used without due information in regard to their pharmacodynamic action We might point out, however, that glucuronic acid, although not previously used for this particular purpose, is by no means a new drug It has been known for two generations and its safe and toxic levels are documented [3] There are numerous references dealing with its administration to experimental animals and to man

Our critics do not document the basis of their expressed fear that by lowering the blood-bilirubin we are driving it into the tissues We have not, to be sure, taken biopsies of the brain before and after glucuronic-acid therapy, but we have observed a diminution of jaundice and biopsies of the subcutaneous fat have shown a reduction in indirect bilirubin coincident with the fall in blood levels

It would seem that the discrepancy between the results of the Boston workers and our own may be explained by differences in technique This matter is now being explored It would seem to us unfortunate if the concern of our Boston colleagues were to result in discontinuance of further studies with this promising therapeutic approach

THE ROYAL COMMISSION AND RESTORATION OF GENERAL PRACTICE

Sir,—Lord Moran, in his evidence to the Royal Commission in January, pictured a professional ladder, consultants on the rungs and general practitioners at its foot, pay corresponding A little later, in *The Lancet* (Jan 25, p 216), he wrote of "the very high standard of general practice as he had known it" That the family doctor is not "what he used to be", coming from a leading medical authority and at a time of reduced public esteem, amounts to a professional calamity The following brief study serves to show that there is sufficient underlying cause for impaired service in the bad conditions of work in general practice Until these defects are remedied by the Ministry of Health it is imprudent to impugn the professional ability of the doctors

During the strain of war, the work of general practitioners was a decisive factor in maintaining national physique and morale Doctors are due to share in the benefits of victory, but the Government leaves them with antiquated machinery to carry on, as best they can, waging their unceasing war against disease and suffering in the community To strike for better conditions is, naturally, rather repugnant to them as it would cause some interruption in the treatment of their patients

Conditions in General Practice

The inherent difficulties of day-to-day practice are daunting enough The doctor's patients are "on his doorstep" or have to be visited in the vicinity Calls come any time, day or night, and epidemics upset his routine and deprive him of his rest Whatever the ailment, it has to be diagnosed, the patient satisfied and anxious relatives coped with Such duties call for all the virtues, a wearing business A haggling and cheese paring attitude on the part of the Government towards them is likely to intensify the present grievance of general practitioners

The bad conditions in practice have persisted since the 1948 Act owing to the complacency of the authorities They involve patients in avoidable suffering and act as a damper on professional zeal and enterprise Among glaring examples is the permission of too high a maximum number of patients This danger is all the greater when modern aids to effective treatment go unprovided These ancillaries should at least equal standards current in commerce Technical and secretarial assistance as well as up-to-date equipment are wanted *Time* for due deliberation is an indispensable ingredient of successful clinical work, and this truth is endorsed by Sir Hugh Watson speaking at and as a member of the Commission [1] when he said, "Assuming that they have the time to do it?" These words reveal a layman's uneasiness about the harassed doctor

Finally, to gain its ideal objective, the cultivation of a healthy nation, not merely to alleviate disease, the Ministry needs to recognise that general practice is the proper and effective agency Only the family doctor has access to the intimacies of family life and his instruction on simple principles of the care of the body will be acceptable to parents The population is now sufficiently educated to cooperate If the Ministry will include this provision in their functions, it will at last be justified in calling itself a *National Health* service The cost will be repaid by the gradual elimination of the huge expenditure on sickness benefits and on drugs at present required owing to ignorant abuse of the human body

Consultant Conditions

This calls for attention, as it proves, by sharp contrast, that the Ministry is quite capable of bettering conditions in the National Health Service

Consultants spend most of their time in hospitals and, there, great facilities have been added since 1948 Notable is the increased number and range of service of registrars Further, thanks to a whole host of ancillaries, professional, technical, and clerical, the consultant can increasingly concentrate on his expert duties Costly complex equipment, too, has been freely supplied The consultants are now paid for hospital services as well as continuing to enjoy the fruits of private practice which have persisted in substantial measure

Consultants are well paid and generously equipped with the means of up-to-date service Family doctors fare badly in both respects It is not the occasion for discrediting their skill, but rather to commend their steadfast adherence to their exacting duties carried on despite the scant attention to the remedy of bad conditions It is said that bad workmen complain of their tools, but good workmen won't work with bad ones The doctor, however, has to do so indefinitely and this although the health of Britain is at stake

A successful outcome of the work of the Commission depends on radical upgrading of conditions in general practice, not merely relieving the present uneasy situation regarding remuneration

Bristol A WILFRID ADAMS

INTERMITTENT HYPERPARATHYROIDISM

SIR,—My interest in the paper by Dr. Whitby (April 26) prompts me to stress a few points As far as I know, only scanty data are available concerning the renal output of calcium in normal persons But according to my knowledge and own experience, I should consider the urinary calcium output of 265 mg per 24 hours on an ordinary diet and 150 mg on a daily intake of 120 mg as distinctly abnormal What is important, however, is to follow the calcium output daily and if possible even in a normal control from the same ward and on the same diet. One would then feel more confident about the interpretation of the results

An early diagnosis of hyperparathyroidism is possible only from a study of the calcium output in the urine First, when renal function is reduced by calcium deposits, there will be a rise of serum-calcium There is every reason to believe that hyperparathyroidism in its earliest stage cannot be diagnosed or excluded by serum-calcium determination alone The data presented by Dr Whitby evidently show that the correct diagnosis has been made at an earlier stage than usual But I still consider his case to have been non-intermittent. More extended data would probably have shown this

THE FUTURE OF THE PUBLIC HEALTH LABORATORY SERVICE

SIR,—As a bacteriologist in the National Health Service I should like to confirm, from my own experience, the criticisms of the conditions of work which are made by "London Bacteriologist" in his letter of April 26

The masquerade as general pathologist which he mentions can be irritating, but the interference with bacteriological work by pathologists-in-charge, particularly of the know-it-all-clinical-pathologist type, is the more serious matter

"Provincial Pathologist" in his letter of April 12 advocates a closer integration of the Public Health Laboratory Service with the hospital services In case anything of the kind does happen in the future, it seems fair to offer to one's bacteriologist colleagues, who may face "integration," a word in season

HOSPITAL BACTERIOLOGIST

EFFECT OF RELAXIN ON UTERINE MOTILITY IN VITRO FOLLOWING TREATMENT WITH ŒSTRADIOL AND PROGESTERONE

SIR,—The effect of relaxin on the tissues thought to constitute the target organs for this substance presupposes pretreatment of the animal with œstrogenic hormones It has been possible to demonstrate this interaction of œstradiol and relaxin both through the biochemical changes induced in the myometrium by these hormonal substances and through the contraction-inhibiting effect of relaxin on the uterus [1] Steinetz et al [2] have shown that the hormonal balance between relaxin and progesterone affects the course of delivery in mice

The reciprocal action between the lipid-soluble ovarian hormones and relaxin may be of decisive importance for an understanding of the significance of relaxin for uterine motility

The aim of the present investigation has been to study the effect of relaxin upon uterine motility in vitro as influenced by these steroid hormones

The animals used in the experiments were virgin female rats (weight 200–250 g) and mice (weight 18–22 g) The animals were castrated 14 days before starting the injections of the respective steroid hormones (Œstradiol benzoate ['Ovex B,' Leo] 1 µg in 0·05 ml peanut oil Progesterone ['Progestin,' Pharmacia] 1 mg in 0 08 ml peanut oil) The injections were given subcutaneously for 3 days (2 µg œstradiol and/or 2–2 5 mg progesterone to the rats, and 1 µg œstradiol and/or 2 mg progesterone to the mice in alternating combinations) The relaxin preparations used were firstly an extract with a biological activity corresponding to about 150 guineapig units per mg and secondly an extract prepared from pregnant sow ovaries by the method of Frieden and Hisaw [3] The animals were killed on the 4th day by a blow on the head The test method with in-vitro experiments has been described earlier [4]

Castrated animals —The motility pattern of the curves had a typical appearance, with high frequency and low amplitude Relaxin did not affect the contractions even in relatively large doses (up to 100 µg , larger doses were not tried)

Animals treated with œstradiol —Obvious reduction or cessation of the activity with relaxin doses down to 1–2 µg There was only slight, if any, impairment of tone

Animals treated with progesterone (these experiments were carried out on rats only) —Relaxin did not affect the spontaneous activity With 500 µg , however, there was slight impairment of tone

Animals treated with œstradiol and progesterone —The spontaneous contractions of the rat uterus were generally reduced in amplitude by relaxin even in very small doses down to 2 µg In contradistinction to the results after treatment with œstradiol alone, tone was obviously impaired The corresponding curves from mice showed the motility to be affected to only a minor degree, whereas an impairment of tone was clearly apparent in all experiments Both the spontaneous activity and the tone impairment were reversible if the doses of relaxin were not too large.

In-vitro experiments after injection of relaxin in vivo —In a number of experiments mice were treated with œstradiol or œstradiol-progesterone with the same doses as previously On the 4th day, 3–4 hours before they were killed, the animals were given injections of relaxin in doses varying between 0 8 and 10 mg subcutaneously in saline solution or 20% polyvidone

---

1 Miller, J W , Kiseley, A , Murray, W J *J Pharmacol* 1957, 120, 426
2 Steinetz, B G , Beach, V L , Kroc, R. L *Endocrinology*, 1957, 61, 271
3 Frieden, E H , Hisaw, F L *Arch Biochem* 1950, 29, 166
4 Wiqvist, N , Paul, K.-G *Acta endocr , Copenhagen* (in the press)

On the assumption that the increase in the water and glycogen content of the myometrium seen in rats 3–6 hours after the injection of relaxin also occurs in mice, one might within this interval expect that in subsequent in-vitro experiments the uterus would not show any spontaneous activity However, in all cases the uterus manifested lively spontaneous activity On the injection of relaxin in vitro there was in animals treated with œstradiol-progesterone no impairment of either the motility or the tone (relaxin doses of up to 100 µg , larger doses were not tried) In the œstradiol-treated animals the uterus reacted relatively weakly in a few experiments and in most cases practically not at all Tone remained unaffected

The results show that, with the doses used, relaxin affects the uterus only when the animals have been pretreated with œstradiol This has been shown previously by Miller et al [1] In this respect œstradiol cannot be replaced by, progesterone as a relaxin-sensitising steroid hormone

After pretreatment of the animals with œstradiol and progesterone, there is striking impairment of tone as well as varying reduction of motility Krantz et al [5] say that the intravenous injection of relaxin in virgin œstradiol-treated guineapigs " invariably resulted in diminution of tone and spontaneous uterine motility " Apart from this, I have not been able to find any data concerning the effect of relaxin on uterine tone

3 hours after a large dose of relaxin injected in vivo the uterus still showed lively spontaneous motility in vitro The time for the maximum effect on the myometrium of the biochemical and physical changes thus does not coincide with the maximum effect upon the motility On the other hand, under these circumstances the uterus is refractory to the direct administration of relaxin in vitro as regards changes in tone and motility As an interesting parallel to this one may mention the effect [6 7] of relaxin upon the uterine motility in women Relaxin had its most pronounced effect during the proliferative phase, a lesser effect during the phase of secretion, and a very inconsiderable effect in the course of labour This may be because endogenous relaxin, especially during pregnancy and possibly also during the phase of secretion, has desensitised the myometrium to exogenous relaxin

PURPURIC ERUPTION DUE TO CARBROMAL

Sir,—More cases of drug rash due to carbromal seem to be about

Carbromal is a capillary-damaging agent, but a relatively weak one, so the purpuric component tends to be unobtrusive and the diagnosis is sometimes missed The eruption, however, which has been fully described by Borrie,[8] is very constant in pattern and distribution It appears first on the ankles and spreads slowly up the lower limbs to the buttocks and hips, later involving, if the drug is not withdrawn, the forearms and other parts There are reddish-brown patches covered generally with fine scales on a background of tiny petechial spots and faint reticulated pigmentation Itching is variable

Carbromal has been regarded as innocuous and can be obtained without a doctor's prescription Apart from tabs carbromal *B P C* it is contained in various proprietary sedative and sleeping tablets, such as ' Abasin ', ' Adalin ', ' Carbrital ', ' Dormiprin ', ' Dormupax ', ' Persomnia ', ' Noctynol ', ' Relaxa ', ' Sedaltine ', and ' Somnotil ' Some compound remedies also contain carbromal, when their trade names and principal therapeutic purpose may not lead one to suspect its presence. For instance, a patient recently presented with what appeared to be a characteristic carbromal eruption, but I was puzzled because she had not been taking ' Persomnia ' or other sleeping pills that I knew contained carbromal She had, however, for many months been having ' Hyperysin ' (anti-hypertensive and vasodilator), which I later discovered has a carbromal content of gr 3 per tablet This led me for future reference to look up the formulæ of other proprietary preparations and I found a carbromal content, surprisingly, in ' Viredrin ' (compound male hormone tablets), ' Fydalex ' (antispasmodic), ' Menopax Oral ' (œstrogenic compound) and ' Menovo ' There may be others

VISITING PARENTS IN HOSPITAL

Sir,—Now that there is widespread agreement that children in hospital should be visited daily by their parents, may I put in a plea for the visiting of ill parents in adult hospitals by their children ?

Department of Child Health,
University of Sheffield

R S Illingworth

AN UNUSUAL INJURY

Sir,—The following injury seems sufficiently unusual to make it worth recording

A man, aged 52, was employed as a press operator in charge of an electrically-operated machine making plastic parts by an injection moulding process The plastic material in the moulding machine was kept at about 450°F (176°C) to keep it sufficiently fluid to enter *all* parts of the die *At one stage in the* process the operator of the machine has to remove the moulded product by putting his hand between the separated valves of the die and, in so doing, across the aperture of the injection nozzle Safety devices normally ensure that no part of the process, which is almost entirely automatic, can take place while the die valves are separated and the safety gate open

On the occasion of the injury, the operator had the back of his right wrist opposite the injection nozzle when, for a reason that has baffled the makers of the machine, he suddenly received a forcible injection of semi-solid polystyrene into the back of his wrist

When admitted to the casualty department shortly afterwards, he was seen to have a knob of solid plastic material, about the size of a pigeon's egg, projecting from the dorsum of his wrist slightly above a line joining the ulna and radial styloid processes It gave the appearance of the end of a bullet-shaped mass A radiograph showed a fracture of the distal end of the ulna without displacement, but the object, which was not radio-opaque, could not be made out

Under a brachial-plexus block an attempt to remove the object by direct pulling was unsuccessful, so an incision was made on either side of the entry hole in the line of the forearm It was then seen that the plastic material had mushroomed out under the subcutaneous tissues, having met the deeper structures overlying the end of the radius, and had also fractured the end of the ulna

The photograph of the specimen shows above, the knob that was projecting from the small entry hole, the central

mushroomed portion grooved on one side by one of the extensor tendons, and, below, the spur which had entered the fracture site in the ulna. The object was shelled out without much difficulty, and, although the subcutaneous tissues were only doubtfully viable owing to the initially high temperature of the plastic, primary closure was attempted. The wrist and forearm were then put in plaster-of-paris splint.

The superficial tissue over the head of the ulna later sloughed, and the defect was covered by Thiersch grafting. There was some residual stiffness of the wrist, but the patient was able to resume work four months after his injury.

I am very grateful to Mr. J. B. Scott for permission to report this case and for his details of the subsequent course of the patient, and to the photographic department of the Royal Berkshire Hospital for preparing the photograph, and the patient's employers for showing me the machinery and technical details related to the accident.

Parliament

Supplies of Poliomyelitis Vaccine

ON May 1 Dr. EDITH SUMMERSKILL criticised the Minister of Health for his failure to ensure that adequate supplies of the vaccine were available to carry out even the modest scheme of immunisation which this country was offering. We were, she pointed out, only offering to immunise children from 2 to 15 years of age and expectant mothers, while other countries were offering to immunise all people under 40, and we must remember that two-thirds of the deaths from poliomyelitis occurred among adults not children. While we were offering two injections, in Canada and the United States three were given. She also thought that the Ministry had not publicised the campaign sufficiently. As a result only 40% of the 10 million eligible had registered by the end of February. The choice of vaccine offered—British or Salk—tended to sow seeds of distrust in the minds of ordinary people. The latest figures, at the end of February, showed that of those registered 571,000 had been given one injection and 2,688,000 were still waiting for the first injection. Thousands more were estimated to have registered in March and April. The initial arrangement to buy vaccine from the United States was not made till September, 1957, and the vaccine took six months to produce and test. She considered that the Minister had failed to order sufficient supplies from the United States soon enough. Delays in the preparation of the vaccine had occurred, both here and in America, but these hazards should have been expected.

Mr. DEREK WALKER-SMITH, the Minister of Health, said that the original order for 5000 litres of Salk vaccine was made in September, 1957, as a bridging operation until British supplies should be available. His expert advice had been then, and still was, that British vaccine, when available, was the best and constituted the best long-term basis for our use. At that time, there was every reasonable expectation that 1958 would see mounting supplies of the British vaccine from at least two large and independent sources. Nobody could have foreseen that British production would be almost at a standstill for several months in 1958. To remedy the lack of British vaccine, 2800 litres of Salk were ordered in January, subject to check testing, with the expectation that they would emerge from the tests, if successful, in the course of April and May. These should have been our main source of supply for the present period. But the American and Canadian suppliers had also met difficulties, which with the almost total postponement of British supplies, had caused a major set-back to our programme. In this emergency the Government had asked the Medical Research Council whether, in view of the shortfall of supplies, American and Canadian Salk vaccine which had passed safety tests in the country of origin could be used in this country without further tests. After considering the present situation the M.R.C. had agreed to this as a temporary measure.[1] A million doses of vaccine, part British, part Canadian, had been issued in the last two weeks, and substantial new supplies would now follow hotfoot and would meet the full requirements of the local authorities, not only for those who had already registered but also for those who would register in the coming weeks and months.

The M.R.C., he continued, had advised this relaxation as a temporary measure, and he wanted to make it clear that this opinion in no way derogated from its general view that British vaccine was best, and that in general the greater the sizes and number of samples tested the better. The Government proposed to restore check testing by the M.R.C. at the earliest possible moment, and looked forward to the possibility that one day we could dispense with the need to use any vaccine containing the Mahoney strain, but this day was not yet, because of the present uncertainty surrounding the British supply position. Meanwhile they would proceed with the work in hand on the basis of the M.R.C.'s immediate advice. There still was a right to reject the Salk vaccine if people preferred to wait for the British vaccine. This was logical, since there was, in any event, no obligation on anybody to register for vaccination at all. People would still have this right of refusal if they prefer to wait, either for the British vaccine or for Salk vaccine check tested by the M.R.C. This was a decision which the individual might find hard. But he could take his doctor's advice.

N.H.S. Contributions

THE National Health Service Contributions Act, 1958, received the royal assent on April 30.

QUESTION TIME

Working Party on Hospital Staffing

Dr. DICKSON MABON asked the Secretary of State for Scotland if he would make a statement on his discussions with the Scottish Joint Consultants' Committee.—Mr. JOHN MACLAY replied: It has been agreed that the study of hospital staffing structure will be conducted on a Great Britain basis, and that interim arrangements for senior registrars will be made, the actual arrangements are to be discussed at a further meeting.

Mr. KENNETH ROBINSON asked the Minister of Health if he would widen the membership of the proposed working party on the medical staffing structure of the hospitals to include representatives of bodies other than the Joint Consultants' Committee and his department.—Mr. DEREK WALKER-SMITH replied: I would refer to the answer given by the Secretary of State for Scotland. My right hon. Friend and I are not proposing any change for our part. Mr. ROBINSON: Is the Minister aware that there are those in the profession who believe that the advice he will receive from the Joint Consultants' Committee may not be entirely detached? Does he not think there is at least a case for having one representative of the senior registrars on the working party?—Mr. WALKER-SMITH: This is a joint committee of my right hon. Friend and myself and the Joint Consultants' Committee in cooperation. The Joint Committee consists of representatives of the Royal Colleges, the Scottish Royal Corporations and the British Medical Association. Its composition is a matter for these three bodies, and my right hon. Friend and I cannot interfere with the professional representation on this working party, which is a matter for the profession. Mr. ROBINSON: Is the Minister not aware that those people are all consultants? As well as representatives from the right hon. Gentleman's department and the Joint Consultants' Committee, could not the Minister include one or more representatives of the senior registrars?—Mr. WALKER-SMITH: The composition of the membership of the working party is not yet decided. We shall have to appoint our members, and I will bear in mind what the hon. Member has said. I cannot, however, interfere with the professional representation, which is a matter for the profession.

Mr. ROBINSON asked the Minister if he would instruct the working party on the medical staffing structure of the hospitals to pay special attention to the understaffing of the mental hospitals and to the need for a substantial increase in the number of psychiatrists in all grades —Mr **WALKER-SMITH** replied The terms of reference of the working party apply equally to mental and other hospitals and no specific reference seems necessary Mr **ROBINSON** In view of the fact that this is by far the most undermanned specialty in the whole of the hospital service, does the Minister not think that at least one word on this problem might be included in the terms of reference?—Mr **WALKER-SMITH** The hon Member can take it that a joint body such as this will be fully aware of all the circumstances relating to the structure and staffing of the mental and mental-deficiency hospitals

---

[1] The Council's memorandum on this subject appears on p. 1016.

Amenity Beds

Mr **JOHN HALL** asked *the Minister if he would abolish* hospital private beds and replace them by the same or greater number of amenity beds —Mr **WALKER-SMITH** replied No, Sir

Mr **HALL** Is the Minister aware that the demand for these amenity beds by those to whom privacy is essential for speedy recovery is far greater than the number available? As a result, they are being forced into private beds at a very great and sometimes extortionate cost? Will he reconsider his decision? —Mr **WALKER-SMITH** I am always prepared to consider proposals both for private or amenity beds where this is possible and where, in the view of the regional hospital board, there is a demand, but there is still a demand for private treatment, and I do not think it would be appropriate to go back on the decision which the House took in this regard in 1946

Russian Vaccine for Multiple Sclerosis

Mr **FENNER BROCKWAY** asked the Minister what information he now had as to the efficacy of the Russian vaccine for multiple sclerosis —Mr **WALKER-SMITH** replied I cannot as yet add to the replies [1] I gave to questions on this subject on April 21 and 28

Mr **SOMERVILLE HASTINGS** asked the Minister if, after having received the information from Russia that he was now seeking, he would issue a white-paper so that both doctors and the public would have reliable information available —Mr **WALKER-SMITH** *replied I do not think this course would be* appropriate since the responsibility for using the vaccine must rest with the doctor, not the patient I will continue to ensure that any information reaching me is made available to doctors who wish to use the vaccine Mr **HASTINGS** Could the Minister arrange at frequent intervals that the latest information which he has to hand is provided for the medical profession through his Ministry or through one of the journals, or in any other way he thinks to be appropriate? Mr **WALKER-SMITH** The ordinary method of communicating information to the medical profession is through the medical Press, supplemented, if necessary, in the case of those practising in the National Health Service, by references in *Prescribers' Notes* I will certainly bear all those matters in mind

Dr **EDITH SUMMERSKILL** Is it not almost unprecedented for a Minister of Health to pass on to doctors information about a vaccine from a foreign country while at the same time he refuses to undertake any tests of the vaccine?—Mr **WALKER-SMITH** What the hon Gentleman asked me to do was to make available in a suitable form to the medical profession such information as we have I must say that I thought that was a very reasonable request, which I said I would try to meet.

Persomnia

Mr **JOHN RANKIN** asked the Minister what had been the outcome of his consultations with the Secretary of State for the Home Department about the sale of 'Persomnia' without prescription from a registered medical practitioner —Mr **WALKER-SMITH** The matter has been referred to the Poisons Board Mr **RANKIN** Without seeking to rush matters in any way, may I ask the Minister whether he has any idea when the Board will report?—Mr **WALKER-SMITH** I have no precise indication The Board is an independent statutory body advising the Home Secretary on these matters, and I have no doubt that it is proceeding with the greatest speed which is compatible with thoroughness and efficiency Mrs **HARRIET SLATER** Is not the Minister aware that the Poisons Board was asked to look at the matter some eighteen months ago?—Mr **WALKER-SMITH** I recognise the hon Lady's interest in this matter over a period, but I am sure she agrees that although speed is desirable it is essential that we get the best and most authoritative advice on this problem

New Posts for Senior Registrars

Mr **KENNETH ROBINSON** asked the Minister of Health how *many specially designated senior registrar posts he intended* to approve, what guidance he was giving to regional hospital boards in this matter, and what would be the higher rate of pay attaching to these posts —Mr **DEREK WALKER-SMITH** replied The number of posts to be approved will be decided on merits after the boards' proposals have been received I am about to discuss with the Joint Committee the guidance to be sent to the boards Rates of pay will be a matter for negotiation

Miners' Boots

Mr **DERICK HEATHCOAT AMORY**, the Chancellor of the Exchequer, announced on April 29 that after considering the representations made to him he had decided to restore the exemption from purchase tax of miners' and quarrymen's protective boots and helmets

Public Health

Vaccination against Poliomyelitis

A FIRST instalment of 2 million doses of Salk vaccine, tested and licensed for issue by the authorities in the U S A, is expected to reach this country next week This will be distributed at once Further batches of Salk vaccine both from new orders and from the pipeline under existing contracts will be arriving, and, according to the Ministry of Health, "there is every expectation that ample vaccine will be available to enable local health authorities and general practitioners to keep the vaccination programme going at full pressure"

Smallpox in Lincolnshire

ON May 4 a case of smallpox was confirmed at Scunthorpe in Lincolnshire The patient, a coloured man, working in a local steel works, was taken to Laceby Smallpox Hospital, near Grimsby

Medicine and the Law

Without Prescription

A PATIENT was admitted to hospital on May 13, 1954, suffering from an attack of boils The house-surgeon in charge of her case ordered a course of streptomycin injections—thirty 0 5 g injections at intervals of eight hours The last injection should have been given at 10 P.M on May 23 In fact, the patient received four more injections than had been ordered, the final injection being given at 6 A M on May 25 On May 26 the patient experienced a sense of giddiness, and from that time she lost her sense of balance She brought an action claiming damages for negligence against the hospital management committee The committee denied negligence

Mr Justice STREATFEILD gave judgment for the patient and awarded her £3000 damages, having found that the ward sister had been negligent He said that it was impossible to approach the case without a feeling of deep sympathy for the patient, but the sole issue for him was whether negligence had been proved Though more was known about streptomycin today than in 1954, he had to judge the case through the spectacles of 1954 The matter for decision fell under three heads

First, had the house-surgeon been negligent in failing to observe the premonitory signs of streptomycin poisoning, or in failing to heed the patient's alleged complaints of giddiness? Secondly, had the nursing staff been guilty of negligence in the same respect? Thirdly, had the ward sister, or the two nurses, been negligent in allowing to be administered, or in administering, the four extra injections?

His Lordship acquitted the house-surgeon and nursing staff of any negligence under the first two heads Under the third, however, it was said that the ward sister and nurses were in breach of their duty not to administer streptomycin unless such administration was in accordance with the directions of a duly qualified medical practitioner The two nurses who had administered the four extra injections had done so without reason to suppose that the doses were other than those prescribed by a doctor Accordingly, they were not negligent.

It was apparent, however, that no precautions had been taken to ensure that the course of injections came to an end at the proper time. For this the ward sister must be held responsible she alone knew that the four extra injections exceeded the prescribed dose.

But did this amount to negligence in law? It would only be negligence if it could be shown that it was the four extra injections which had caused the damage and if the ward sister ought reasonably to have foreseen that damage might ensue On the evidence his Lordship was satisfied that it was the final injection that had caused the damage Accordingly she was guilty of negligence for which the committee could be made vicariously responsible Had a doctor in fact prescribed the additional injections which had in fact been administered, negligence might well not have been established, but the position differed where there had been no prescription To hold otherwise would be to deprive the patient of the protection of the trained mind of a doctor which the law sought to give, and possibly to enable a nurse to take it upon herself to administer streptomycin whenever she thought fit

4.30 P.M Mrs D M Shotton Pelvic Tuberculosis

Notes and News

EMPIRE RHEUMATISM COUNCIL

Last year the Council appealed for £250,000 to finance a ten-year programme of intensified research This year at the annual general meeting, held in London, Dr W S C Copeman the chairman, reported that, though £175,000 was still urgently needed, with the funds that had been received the Council's activities had been extended, and the Council had endowed for ten years a new chair of rheumatology in the University of London at the Postgraduate Medical School[1] The Council has already endowed a chair at the University of Manchester

Two research fellows have this year completed their work for the Council Dr J K Norymberski, whose biochemical studies of the steroids are already being put to practical use in measuring chemically the effect of hormone remedies, and Miss I H Muir, who isolated chondroitin sulphate, which is present in connective tissue and joints The Council's trials of drugs continue Nine centres took part in a three-year trial comparing the long-term effect of cortisone and aspirin in the treatment of rheumatoid arthritis,[2] and a trial of gold therapy for arthritis is at present being carried out at 27 centres The Council's mobile field unit, which is the only one of its kind in the world, has had an active year, and Dr J S Lawrence, the director, reports the start of two genetic surveys The first has already produced interesting and unexpected results suggesting that there may be two forms of rheumatoid arthritis, one with and one without hereditary characteristics Random sample studies show that, contrary to general belief, rheumatoid disease may be present as a disorder of the cervical spine The second genetic survey, on the relatives of patients with multiple osteoarthritis, is still in its early stages, but preliminary results show a definite familial trend At the West London Hospital, under Dr J D Robertson, a biochemical test has been adapted to control the use of adrenocortical hormones As a result it has been found that only initial doses need be high, and that patients may continue their treatment at home under out-patient supervision

NEUTRALITY OF MEDICINE IN WAR

In Paris from June 5 to 7, with the President of the Republic as patron, will be held the Congres International de la Neutralité de la Médicine en Temps de Guerre

Outlining the policy of the committee, founded in 1952, which has taken the initiative in France, Prof Charles Richet, its president, says that the first duty of doctors, in war as in peace, is to save life In the second world war there were some 30 million deaths in Europe, and half of these were "useless" they could have been avoided without affecting the course of events The measures most important for reducing the brutality of war are those laid down by the International Committee of the Red Cross enemy prisoners and wounded must be treated as human beings, with humanity, and civilians in occupied regions have the same right to protection as the prisoner-of-war The Geneva conventions must in future be made more widely known so that they can be less easily violated In each country a group of doctors and of jurists who understand the conventions should be set up in time of peace, so that they can be sent immediately to places where fighting breaks out These groups should have a special international status, so that they will be accredited to all nations At present no country has at its disposal the body of doctors and lawyers whom it would need if it undertook the functions of a protecting Power—well-qualified volunteers who would be capable of taking over key administrative and medical posts in the country at war Perhaps most important in the long run, an intergovernmental organisation should at once be formed, able to draw on material and economic resources and a pool of medical personnel

"Take a possible case Two countries are at war After a fortnight there are, on each side, 500,000 casualties—wounded, shocked gassed, burned, infected How, with only their own doctors, can these countries cope with this situation? How, in a single country, can one find the 30–50 tons of human blood or plasma needed each day? The reserves of dressings and gas-gangrene serum and tetanus serum of one country may well be exhausted in a month To put it in another way, a country which is medically isolated could not give proper care, in war-time, to more than one casualty in three or four"

Medical aid from outside, given in the spirit of the International Red Cross, with the absolute impartiality which the Red Cross could assure, would relieve much suffering without affecting the outcome of the war and probably without prolonging it by a day Perhaps the seriously wounded and sick could be taken into hospital in neutral territories, and remain interned until hostilities cease If, as is possible, the war affected the whole world, the committees of doctors and jurists, with supranational status, would be morally neutral They would be in the best position to enable our shattered civilisation to survive

Particulars may be had from the Comité de la Neutralité de la Médicine en Temps de Guerre, 37, rue de Bellechasse, Paris VII

CANDIED SENIOR REGISTRARS

The difficulties of senior registrars are at the moment being discussed at the highest level A more unorthodox but no less discerning approach to their problems has been made by Edward Candy in his novel *The Graver Tribe*[1] He begins by describing the mixed feelings of disappointment and elation aroused by the appointment of the new surgeon at St Chad's hospital, and for good measure he includes the extramural problem of a marriage that has gone wrong and the ethical problem of whether it is right to operate on an unwilling patient even to save his life The reader may well have the uneasy feeling that the matron of St Chad's is Miss Compton Burnett in disguise, for both the staff and the patients speak with the stylised formality and devastating frankness of her characters But Mr (or is it Dr ?) Candy does not follow her practice of confining melodrama to the wings St Chad's is a lively hospital, and a young surgeon there thinks nothing of hurrying from the theatre where he has performed an emergency operation to the medical school where he wields a stomach pump on his alcoholic chief who has just attempted suicide

PREMATURE MARRIAGE

Delinquency and unhappiness are usually more dramatic, though less pleasant, than uneventful stable behaviour and happiness, and we are apt to forget that the bad publicity which young people too often receive today is earned by a small minority We are also apt to forget how often the unsatisfactory behaviour of even that small minority may be due to what Dr John Highet[2] lately described as a "barrage of potentially corrupting adult practices and influences" As examples of these he cited the emphasis on sex, glamour, sumptuousness, and luxury, on force, violence, deceit, and dishonesty, on the philosophy of "anything goes" and "nothing sacred" A recent survey[3] of 400 young people showed that nearly a quarter thought that there was nothing wrong in an engaged couple having sexual intercourse Again in recent years official reports show that 2 out of every 3 first babies born to brides aged sixteen to nineteen were conceived out of wedlock These extramarital conceptions are one reason for the present trend toward earlier marriage In Scotland 1 bride in 7 is under twenty and 1 in 4 is under twenty-one, while the proportions are even higher in England But many of these young people freely choose to marry young, perhaps understandably in view of the emphasis which is laid on sex in the world in which they live Another factor in Dr Highet's view is what he terms the "irresponsible" recommendation of early marriage by some doctors This recommendation, he suggests, is based solely on the ground that it is best for a young woman to start her

family as early as possible. But there is another side to the picture, and he believes that it would be a real service to point out to young people that it has been estimated [4] that, if recent trends continue, then on the average 1 in 4 of the girls now marrying between sixteen and eighteen years of age will have been divorced by the twentieth anniversary of their marriage, compared with 1 in 10 marrying between nineteen and twenty-two and 1 in 16 marrying between twenty-three and twenty-seven.

MARGARET DE SOUSA DEIRO FUND

The scope of this fund, which was set up to help indigent gentlewomen with early pulmonary tuberculosis, has lately been widened by an order of the Charity Commissioners, and the trustees may now apply any income not needed for the original purpose to the care, reablement, and aftercare of indigent women with pulmonary tuberculosis or any other disease of the chest

The fund can make grants to cover the cost of treatment, when this cannot be carried out in suitable conditions under the National Health Service, and grants towards convalescent holidays after institutional treatment. In approved cases the trustees can also give financial help for reablement and convalescence. By its constitution the fund is unable to help patients with chronic illness who have no prospect of returning to employment. Further particulars and application forms can be had from the trustees, 1, New Court, Carey Street, Lincoln's Inn, London, W C.2.

MEDICAL FILMS

A NEW film, *The Treatment of Sports Injuries* (16 mm, sound, colour, 22 minutes, Great Britain, 1957), is of special interest to school doctors and those associated with sports clubs

The film opens with the statement that most sports injuries, given adequate first-aid, treatment, and rehabilitation, recover rapidly The causes of injuries are direct and indirect trauma, strong muscular contraction, and postural strain, and their treatment consists primarily in the control of bleeding and support of the injured part. Recovery depends as much on the effort of the patient as on the treatment by the doctor The management of a sprained ankle is shown in detail The second half is devoted to specific lesions, including knee injuries sustained in cricket, ski-ing, and football, tennis-elbow, and a tear of the hamstring muscles of athletes The film ends with a summary and a call for closer cooperation between the doctor, the hospital, and the trainer of sportsmen, not only in the treatment, but also in the prevention of injuries

Although some may disagree with certain details of treatment, the principles are sound and the emphasis on home exercises and on the value of supervising correct posture during training is noteworthy

Copies of the film are available, free of charge, from T J Smith & Nephew, Ltd, Medical Department, Neptune Street, Hull

The Grand Rounds—1 Acute Abdominal Problems (16 mm, sound, black and white. 57 minutes, U S.A, 1956) is one of two film records of American television discussions now available in this country Three abdominal surgical problems are considered

The first case was of a man with a long history of asthma and bronchitis, severe scoliosis, and upper abdominal pain of recent onset Film taken when he was admitted to hospital was shown and radiographs and laboratory findings were presented After discussion by the panel of various diagnoses, film taken at operation was shown, and the results and postoperative course were debated The second case was a man who had been admitted with an inflammatory condition of his face and an upper respiratory infection He had subsequently collapsed and a mass was detected in the left upper quadrant of his abdomen The diagnosis was discussed and the results of laparotomy are revealed The third case was of a man, aged 71, with a long history of peptic ulcer and increasing pyloric obstruction who had been admitted to hospital two weeks previously with a perforation of his ulcer This had been treated conservatively with success until that morning when the patient had had a severe hæmatemesis The ensuing discussion dealt with the conservative treatment of perforations—described as 'widely practised in England'—the effect of long-continued gastric intubation, the incidence of hæmorrhage as a complication of perforations in the elderly, and the course to be followed in this case.

This is an interesting record from which some valuable diagnostic points may be gleaned The discussion by the experts is lively and stimulating, and Dr Leo G Rigler's analyses of the X rays are informative

In the second film, *The Grand Rounds—2 The Cardiac Patient in Stress, Work, Surgery Pregnancy* (16 mm, sound, black and white, 90 minutes, U S A., 1956), a further three cases are discussed.

The first case was of a man who four and a half years earlier had been admitted with upper abdominal distress for cholecystectomy, but had had a cardiac infarction before the operation After the panel had discussed the argument for elective cholecystectomy, the patient was taken to the operating-theatre, where the anæsthetist discussed the anæsthesia for such a case A debate on postoperative management followed The second case was of a woman, aged 35, in the fourth month of her seventh pregnancy with signs of mitral and aortic stenosis Her heart sounds were demonstrated with an amplifying stethoscope and her radiographs were shown The panel discussed various aspects of cardiac disease in pregnancy and labour The third case, of a man with a cardiac infarction, stirred up a provocative discussion on management of cases in which opposing views were expressed by Dr Sam Levine and Dr Paul Dudley White

These films are well worth showing to any group of physicians and surgeons, and medical students may find the diagnostic problems useful

They may be borrowed, free of charge, from Upjohn of England, Ltd, 4, Alford Street, London, W 1

University of Cambridge

On April 26 the following degrees were conferred

M Chir —I W Broomhead *W K. Douglas.
M.B, B Chir —*A. D H. Pooler
M.B —J N Stenhouse

* By proxy

Guy's Hospital Medical School

Prof A. G Brom will deliver the Carbutt lecture on Tuesday, May 13 He is to speak on recent developments in cardiac surgery Dr Hugh B Cott will give the Fison lecture on Friday, May 30 His subject will be protective coloration in animals Both lectures will be held at 5 P.M at the school, London Bridge, S E 1, and tickets may be had from the dean.

Charing Cross Hospital Medical School

Sir Howard Florey will deliver the Huxley lecture at the school, Chandos Place, London, W C 2, at 5.30 P.M, on Thursday, May 22 He will speak on the changing emphasis in medical research

Institute of Cardiology, London

Dr Howard Burchell of the Mayo Clinic, Rochester, Minnesota, will give the St. Cyres lecture for 1958 at 1, Wimpole Street, W 1, on Wednesday, June 4, at 5 P M. He is to speak on pulmonary hypertension in congenital heart-disease

Ciba Foundation

The trustees of the Ciba Foundation are offering in 1959 not less than five awards (£300 each) for investigations into the basic problems of ageing Entries must reach Dr G E. W Wolstenholme, director of the foundation, 41, Portland Place, London, W 1, not later than Jan 1, 1959

The Foundation's lecture on research on ageing will be given this year by Prof F Bourliere of the Laboratoire de Physiologie Faculte de Medecine de Paris, on Thursday June 19, at 5 P.M., at the Royal Institution, 21, Albemarle Street, London, W 1 He is to speak on the comparative study of age changes

Simpson-Smith Prize

As the subject for this prize for 1959 the Institute of Child Health has chosen Spina Bifida.

The prize (100 guineas) is open to men and women from the British Commonwealth or the Republic of Ireland who are engaged in the practice of surgery A copy of the rules can be had from the secretary of the Institute, The Hospital for Sick Children, Great Ormond Street, London, W C 1 Essays must be submitted not later than Dec. 31, 1959

---

International Congress of Clinical Pathology

This congress will be held in Madrid from June 13 to 17, *1960* Further particulars may be had from *Dr José Aparicio Garrido, Facultad de Medicina, Pabellón Nr 2, Ciudad Universitaria, Madrid*

Marlborough Day Hospital

On Monday, May 19, at 8 15 P M at the hospital, 38, Marlborough Place, London, N W 8, Dr E M Bluestone, formerly director of Montefiore Hospital, New York, will speak on social psychiatry

Work Study in the Hospital Service

The Chartered Society of Physiotherapy is arranging a conference on this subject, to be held on Oct 17 and 18 at the Westminster Medical School, S W 1 Further particulars may be had from the secretary of the society, Tavistock House (South), Tavistock Square, W C 1

Royal Institute of Public Health and Hygiene

Dr B G B Lucas will give the Bengué lecture for 1958 on Oct 20, at 5 P M His subject will be artificial aids in the control of the circulation Brigadier J S K Boyd will give the Blackham lecture for 1958 on Tuesday, Nov 11, at 4 P M on yellow fever and its prevention Both lectures will be given at the institute, 28, Portland Place, London, W 1

Centenary of Babinski

The Société Française de Neurologie, at its Réunion Neurologique Internationale in Paris on June 2, is celebrating the centenary of the birth of J Babinski

The president, Prof Raymond Garçin, will speak on Babinski's work, *Sir Francis Walshe on his place in modern neurology,* and A Tournay on Babinski the man The two ensuing days will be devoted to a symposium on the cerebellum

Legislation on Mental Health

Opening the annual conference of the Institute of Hospital Administrators in London on May 4 (*The Times*, May 5), Mr Derek Walker-Smith, the Minister of Health, reaffirmed the Government's acceptance of the need to revise the law relating to mental health They intended, he said, to promote legislation as soon as possible, though not in the current session of Parliament He hoped that from the discussions on the Royal Commission's recommendations there would emerge a new and improved pattern of hospital administration

College of General Practitioners

Applications are invited, before Sept 1, from members of the college for not less than fifteen Upjohn travelling fellowships of up to £200 each in value

The object of these fellowships is to enable general practitioners to undertake postgraduate study (for at least two weeks) at their old teaching hospitals or at any other hospitals, clinics, health centres, or general practices of their choice They are to be presented annually, by Messrs Upjohn of England Ltd, to members of the college who are in active general practice in the United Kingdom or Eire Further particulars may be had from the secretary of the college, 41, Cadogan Gardens, London, S W 3

Royal Commission on Remuneration

The Royal Commission on Doctors' and Dentists' Remuneration were taking evidence last Thursday, May 8, from representatives of the Society of Medical Officers of Health and the Association of County Medical Officers of Health of England and Wales

On May 15, representatives of the Medical Research Council, and the Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom have been invited to attend

---

A 16 mm film, entitled *The Hypnotic Treatment of Psychogenic Illness*, has been made at Belmont Hospital, Sutton, Surrey It may be borrowed free of charge by hospitals and medical societies on application to the group secretary at the hospital

Dr H Seaward *Morley* has been appointed a member of the council of the Board of Registration of Medical Auxiliaries

The flag day for the National Association for *Mental* Health and the *Mental* Health Research Fund joint appeal will be held this year on Tuesday, July 8, in the *Metropolitan* boroughs

A symposium on carcinoma of the lung was held by N A P T in London last November, the proceedings have been published as a booklet (pp 48, 6*s*) obtainable from N A P T, Tavistock Hous North, Tavistock Square, London, W C 1

The *Bishop of St* Edmundsbury and Ipswich will dedicate a memorial garden at Golders Green Crematorium to the memory of the late Lord Horder on May 30, at 3 P M Invitations may be had from the secretary, The London Cremation Company Ltd, 45, Nottingham Place, London, W 1

The United Hospitals' Choir, which rehearses on Thursday evenings at St James's and St Peter's School, Great Windmill Street, London, W 1, invites new members to join Further details may be had from the secretary, Miss J Magrath, 18, West Side, Clapham Common, London, S W 4

The annual dinner of the Indian Medical Service Dinner Club will be held at the East India and Sports Club Limited, St James's Square, London, S W 1, on Friday, June 13, at 7 30 P M Tickets may be had from the secretary of the club, Medical Board Room, Commonwealth Relations Office, Matthew Parker Street, S W 1

St John's Wood Church, London, N W 8, has chosen this year as the theme of its World Church weekend, on May 10 and 11, the Church and Disease The speakers will include Dr Desmond O'Neill, and the programme ends with a discussion on "What's it got to do with me?" in which a surgeon, a general practitioner, *a children's officer, and a committee member of the St Marylebone* Almshouses and Housing Associations will take part

The first issue of *District Nursing*, the official journal of the Queen's Institute of District Nursing, has appeared The new publication, which has taken over the old *Queen's Nurses' Magazine* with a view to developing its scope, intends, in its own words, "to meet the needs of the technical and administrative worker in the domiciliary health field" It is to be published monthly and costs 1*s* The editorial offices are at 57, Lower Belgrave Street, London, S W 1

CORRIGENDA *Slough Industrial Health Service*—In a note on April 26 (p 917) we stated that the occupational hygiene service was controlled jointly with the London School of Hygiene and Tropical Medicine We are informed that control now rests wholly with the Slough Industrial Health Service

Fat-mobilising Activity of Human Urine—In fig 3 of the article by Dr T M Chalmers and his colleagues (April 26, p 866) the specific activity as percentage of control was mean ±2 S E M and *not* mean ± S E M

SOME PATHOLOGICAL ADAPTATIONS IN THE PERIPHERAL CIRCULATION*

J HENRY DIBLE
M B, LL D Glasg, F R C P
EMERITUS PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LONDON
From the Research Laboratories, Mount Vernon Hospital, Northwood, Middlesex

ADAPTABILITY, in living organisms, is a prerequisite of survival It is fundamental to the doctrine of natural selection, and on the smaller stage of the human species it is a daily experience Within the yet narrower compass of the bodily economy the same truth holds and persists, though in less obvious fashion, down to the ultimate constituents of the body—the cells

The cell is in many cases more adaptable than the organ of which it is a part, and the organ than the body as a whole The survival and execution of the functions of cells depend upon the circulation The circulation has three main parts the cardiac pump, the conduit tubes, arteries and veins, and the metabolic area, the capillaries A great deal has been discovered about the adaptability of the heart, but rather less about that of the conduit system, whilst the changes in the capillary area—in a sense the latest comer in the field of physiological research —are still less completely known

When we pass across the grey band which divides what is physiological from what is pathological, and enter the dark area which is the true domain of pathology, we are in a territory full of pitfalls and quagmires The investigator faces the double difficulty that he has both to try to find out the anatomical changes in an organ—changes which essentially are not static but increase with disease and decline with recovery or become adapted to a permanently abnormal state of affairs—and to interpret these as effects in the organ and the body In pathological investigation, as is logical, anatomy has generally led physiology, and in what I have to say I shall be concerned chiefly with anatomical changes

I am very conscious that my discourse may contain more of speculation than Matthew Stewart would have approved by his own high standards, but it is my purpose to be suggestive rather than dogmatic and to deal with matters which cannot at the moment be regarded as settled

Hyperæmia and Ischæmia

The morbid changes in a system of conduits can result in a general way either in their widening or narrowing, and in a supply of either more or less blood Unfortunately for the investigator it is not as simple as this, since "blood" is not a substance of constant composition, nor are the tubes through which it flows of fixed size, structure, or function The blood is varying all the time it is making the circulatory circuit, and (what is more) *it is varying at* different and inconstant rates and travelling at different and variable speeds

In an attempt to simplify the matter—for it is the aim of the scientist to reach general principles—we ignore much of this and roughly divide the conditions we encounter into *hyperæmia* and *ischæmia* The former we subdivide into *active* and *passive*, and the latter into *acute* and *chronic* In this lecture I am concerned essentially with the arterial side of the system, so we need consider only active hyperæmia and ischæmia Active hyperæmia is due to relaxation (local or general) of the arterioles, ischæmia to functional constriction or anatomical occlusion

Active Hyperæmia

Hyperæmia is an important part of the inflammatory reaction, but with this aspect of it I do not intend to deal The condition of chronic active hyperæmia, meaning an excessive supply of fully oxygenated blood to tissues having normal requirements, is a rarity and intrigued the great John Hunter as a possible cause of hypertrophy It certainly occurs with increased demand in hypertrophy, but it seems to be secondary, or at most coincidental It is sometimes seen in malignant growths, as for example in certain acute carcinomata of the breast and in some sarcomata which have many of the features of acute inflammation and are characterised by very rapid growth An obvious case of such a condition, occurring without abnormal tissue demands, would seem to be arteriovenous fistula, but this is not really admissible, since it involves complicated changes on the venous side producing abnormal pressure in the venous system and symptoms of chronic venous congestion Nevertheless the skin temperature is raised in the chronic phase, there is an increase in the size of the limb, and, if the fistula is present before the epiphyses have united, the length of the bones is increased

It might be thought that the effects of chronic active hyperæmia could be produced by keeping animals in an atmosphere of increased oxygen tension for long periods, but this gives no answer, because damage to the lungs results and causes death with pneumonic changes which produce anoxia Similarly, in local venous obstruction, such as may result from destruction of the venous valves, the picture is complicated by stasis, and here too we cannot disentangle the effects of anoxia

I would, however, like to quote a rather remarkable case I saw recently

A man of about 50 had his left leg flexed and useless for many years from some chronic local venous disease, which for the past three years had been complicated by ulceration The venous valves were destroyed by old thrombophlebitis There was chronic osteomyelitis of the lower ends of the tibia and the fibula with much formation of new bone The skin over his leg was ichthyotic In spite of prolonged disuse this leg was larger than its fellow, which appeared quite healthy and on which the patient walked, and arteriography showed all the arteries in the diseased limb to be unusually dilated The increase in size of the disused calf-muscles was not due to muscular hypertrophy but to a great infiltration with fat between atrophied muscle-bundles—so much so that a transverse slice of the leg, including the bones, floated

This recalls the appearance of the leg muscles in pseudohypertrophic myopathy in children The factors which lead to the latter disease are unknown, but the present case may provide a pointer, in that we had a combination of disuse plus chronic active congestion in the arterial circulation, the latter presumably due to the chronic inflammation in the bones, together with venous stasis

Ischæmia

When we come to consider ischæmia, the problem is more manageable, since from its nature it is so often associated with arterial disease It is essentially a process which manifests itself at the periphery of the arteriolar/

---

* Matthew Stewart memorial lecture given in Leeds on Nov 28, 1957

capillary system This, I should point out, is not synonymous with the extremities or with the body's surface The peripheral part of the liver's circulation, for example, is at the centres of the lobules, and of the kidney at the glomerular tuft and just beyond The extremities and the skin, however, attract our special attention because the main effects of ischæmia—colour changes, pain, œdema, hæmorrhage, and eventually necrosis—are most readily seen and experienced there

Acute peripheral ischæmia—Grave ischæmia may occur without anatomical arterial disease, as a result of peripheral spasm We are all acquainted with physiological degrees of this in cold fingers and toes, and with more severe grades in chilblains and frostbite A special case is the Raynaud phenomenon, where it is suggested that there is some unexplained oversensitivity to cold in the digital arteries Acute peripheral ischæmia resulting from central circulatory deficiency, severe enough to produce gangrene, is sometimes seen and was mentioned by Paget in 1853, when he wrote of a man who cut his throat and lost so much blood that "the nutrition became impossible in one of those parts to which blood is more difficultly sent, and before he died his nose sloughed" Brodie speaks of a drunken man who "being bled to an inordinate extent was seized with gangrene of both feet" Such an acute condition was recently encountered in the case of a man of 62, suffering from left ventricular failure and coronary disease, who developed gangrene of the nose and the left ring-finger, with early gangrene of other fingers Here we had some information about the deep peripheral circulation, since the effective renal blood-flow was measured at the time and found to be only 34 ml per min (normal 700 ml per min) At postmortem examination advanced stasis was found in the glomerular capillaries, similar to that which precedes symmetrical renal cortical necrosis In another case, in a young woman, this renal condition was fully developed, along with gangrene of the nose, cheeks, and fingers These are special examples of acute peripheral ischæmia severe enough to cause necrosis but not due to any organic primary peripheral vascular disease

Chronic peripheral ischæmia—The basis of chronic ischæmia is in the arterial system, and the most common cause is narrowing of the arteries due to atherosclerosis and its effects

Degeneration or Incrustation?

For almost a hundred years the teaching of Virchow dominated our ideas on the genesis of atheroma, but recently the whole of this has been called in question by Duguid, who has revived and re-presented in modern form the earlier view of Rokitansky—that the atheromatous plaque (the hallmark of the disease) is an "incrustation" on the inside of the artery Virchow held that it was a degeneration in the intima with lipoid deposition and that the other changes were secondary to this Duguid regards a thrombus as the starting-point and illustrates its development in the way shown in his papers (1949 et seq) These views have aroused great interest, and I should like to consider them briefly, and especially the objections that have been raised against this simple explanation

(1) It has been asked why, if a thrombus becomes an atheromatous plaque, do we so commonly see quite a different condition developing from a thrombus—often alongside an atheromatous plaque (fig 1), an appearance well known to pathologists? I shall leave this point for the moment and come back to it later, for it is fundamental to much of what I have to say on this matter

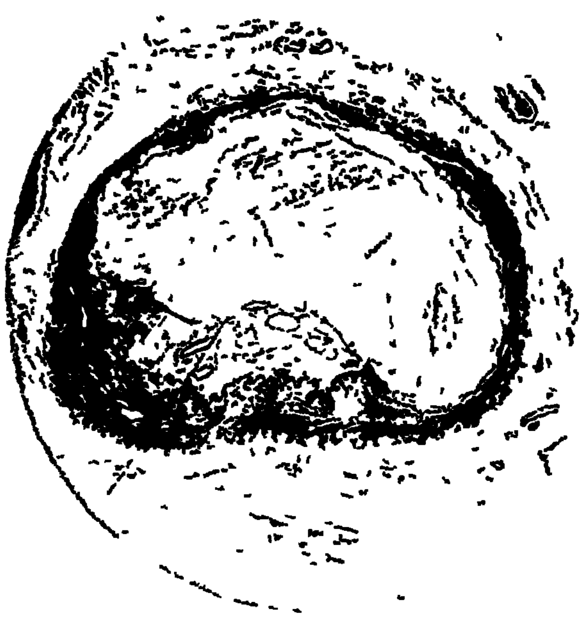

Fig 1—Atherosclerosis, followed by thrombosis and canalisation in anterior tibial artery Note internal elastic lamina opposite recently canalised area and its absence opposite older atheromatous lesion (×15)

(2) How are we to explain the great accumulation of lipoid substances in the plaque—a quantity which is often far greater than can be formed by the breakdown of a local thrombus? This difficulty is common to either theory The lipoid has to come from outside, and the mechanism may be the same in either case The point gives us no assistance But I think it is associated with one or more red herrings—if I may introduce such a metaphor—which have helped to maintain Virchow's view

(1) There is the association between atheroma and diabetes In the days before the discovery of insulin, diabetes was treated by a high-fat and high-protein diet and carbohydrate starvation Under such a regime heavy lipæmia was a common result, and diabetics showed extensive atheromatous lesions with heavy accumulation of lipoids I believe the explanation to be not that the atheroma was caused by the lipæmia but that —diabetes being a disease in which lipoids tend to accumulate —this feature was favoured and exaggerated by the abnormal quantities of lipoid in the blood and tissue fluids

(b) The second red herring was the discovery that by feeding rabbits on large amounts of cholesterol, lesions resembling atheroma could be induced in the aorta More critical analysis has shown that the analogy is not really very close, and these investigations have contributed little if anything to the solution of the problem Under modern treatment of diabetes I think we must review the association between the diseases My own experience, over the past twenty years, has been that diabetics do not come to operation for ischæmia due to atheroma any earlier than non-diabetics (71 5 and 71 years respectively), and on such a basis there are no grounds for believing that peripheral vascular disease is influenced by diabetes

(3) Why are there no iron salts in a formation claimed to have developed from a thrombus?

(4) The fate of arterial thrombi in a disease in which they are a main feature—Buerger's disease—is very different

(5) Thrombi in veins only rarely develop into atheromatous plaques But veins have quite a different anatomical structure and lack the features which, I suggest, play a part in the formation of the plaque

The Thrombus and the Reaction

I believe that the truth of the matter lies with Duguid, and that the difficulties I have mentioned are answerable and are related to the nature and composition of the "thrombus", and to the vascular reaction In fact, if we meet the first of these objections we have the answer to most of the others

There is no doubt that we can find abundant evidence that certain thrombotic masses can be incorporated in the vessel wall and give rise to lesions indistinguishable from atheromatous plaques

Figs 2 and 3 show the popliteal artery of a man of 42 with Buerger's disease, with a thrombus extending down as far as the anterior tibial artery The thrombus which only partially occludes the vessel, has become covered with endothelium, and is in process of incorporation into the artery wall, being covered on its inner surface with a living cellular membrane formed in connection with the tunica intima Underneath there is a central formless mass corresponding to the necrotic centre of the atheromatous plaque, and we also see a "splitting" of the internal elastic lamina at the margin of the plaque, such as is so often figured in descriptions of atheroma. Beneath the thrombus the internal elastic lamina is still intact.

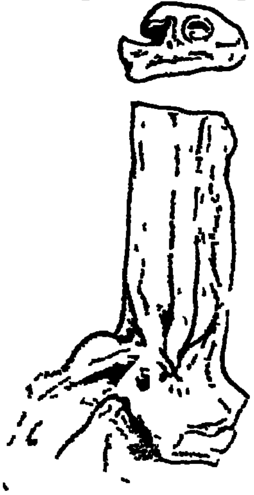

Fig 2—Thrombus, partially occluding tibiopopliteal trunk, becoming incorporated into lateral wall of artery in man aged 42, with Buerger's disease.

If we agree then that a thrombus can develop into a lesion having the histological characters of atheroma, we come back to the question Why do not all thrombi do so? The answer is the one I have already suggested—that this depends on the nature and completeness of the thrombus and the reaction of the arterial wall We are inclined to ignore the fact that "thrombi" vary greatly, from purely platelet thrombi to massive clots formed from whole blood and containing all its chemical and cellular constituents in approximately normal ratios I agree with Duguid, in his later papers, that it is not the gross thrombus, figured in his original paper, which ordinarily undergoes a metamorphosis into an atheromatous plaque the thrombus in which this change takes place is the one constituted mainly of fibrin and platelets, which is slowly deposited, is eccentrically placed, and may grow by slow accretion

We have learnt of late, to some extent since arterial grafts have come into use, the great growth activity of the endothelium which enables it to line a graft with great speed, and it is fair to assume an equal activity in the covering in of a mural thrombus I would modify Duguid's original diagram to one which takes rather more account of the activity of the endothelial tissue and of the vessel wall I think there is no doubt that the endothelium and cells associated with it can form reticulin and collagenous tissue

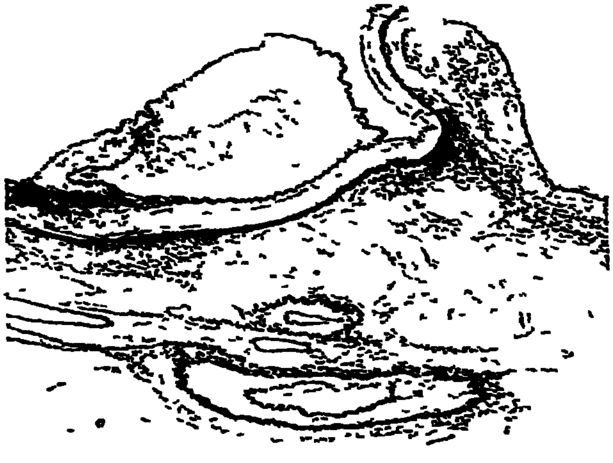

Fig 3—Section of same artery as in fig 2, showing incorporation of thrombus and formation of new elastic layers. (×6 5)

Organisation of Thrombus

Crawford and Levine (1952) have emphasised this, Geiringer (1951) has mentioned superficial giant capillaries proceeding for a short distance from the lumen, whilst Duguid (1949) speaks of the collagenous metamorphosis of the superficial layer of thrombus beneath the endothelium Under certain conditions this endothelial activity may be enormously extended and result in the canalisation of the thrombus (Dible 1958), but in the special type of mural thrombus leading to the formation of the atheromatous plaque the development ceases, unless further accretions form on the surface The atheromatous plaque, therefore, becomes as it were encapsulated and thrust aside from the lumen, and there is little or no persisting

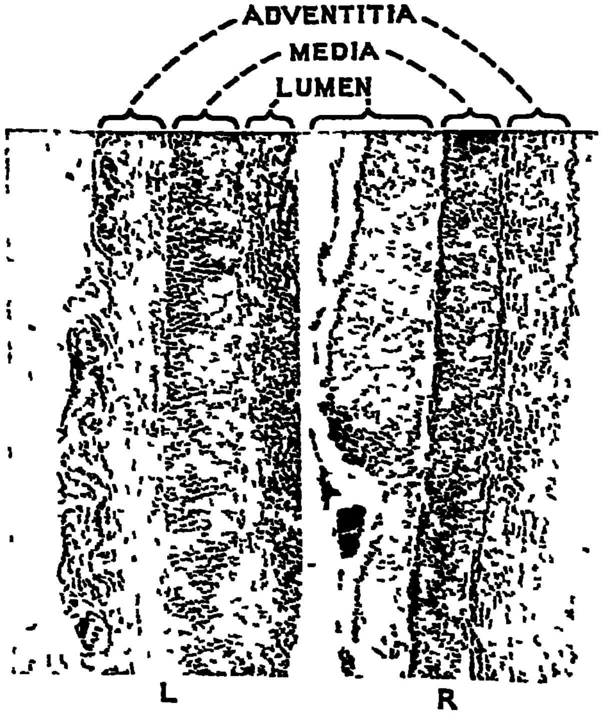

Fig 4—Two ulnar arteries from the same patient with (L) old canalising thrombus, and (R) very recent thrombus. Note increase in vasa vasorum of middle coat in left vessel and absence of such reaction in right. In spite of this vascular response vasa vasorum do not penetrate to thrombus (×36.)

stimulus to further change from the side of the lumen, but, if the area of narrowing is converted into a complete occlusion by the later formation of an acute thrombus, this will have a different fate Fig 1 shows the outcome of such a condition, but the second thrombus has undergone canalisation, which is quite another form of adaptation of the damaged circulation and a different pathological process, of which I shall speak in a moment

So far we have ignored the rest of the vessel wall The middle coat does not accept the presence of a thrombus passively but reacts, notably by an increased prominence of the vasa vasorum (fig 4), which in the case of atheroma show a limited tendency to vascularise the plaque But here there is an apparent barrier, and this, as I have suggested elsewhere (Dible 1958), seems to depend upon the presence of an intact internal elastic lamina I believe that, in a healthy vessel wall, this opposes an impassable bar to the ingrowth of vessels from the media, but in the depths of the atheromatous patch the lamina commonly breaks up or disappears as the patch grows older, with the result that the barrier is removed and some vascularisation of the patch may be seen on its deep side

A good deal of attention has been paid, notably by Winternitz et al (1938), to hæmorrhages into the depths of atheromatous plaques in the coronary arteries The more advanced of these invading vessels have a capillary structure and may be the source of hæmorrhage, which seems particularly liable to occur in a pulsating vessel containing rigid and sometimes calcified plaques, in which sheering strains would tend to develop

Canalisation of Thrombus

In dealing with the possible and limited vascularisation of the atheromatous plaque I have been leading up to the quite different fate which an intra-arterial thrombus may undergo—a thrombus such as I have visualised as finally occluding our narrowed atheromatous vessel (fig 1), or produced in the healthy artery of a young person, or as develops in Raynaud's disease

The expression "organisation" is often used in connection with the changes in an occluding thrombus—I think not wholly accurately, for the process is not exactly comparable to the conversion of a fibrinous exudate, or a mass of effused blood, into living fibrous tissue, such as is seen in the organisation of a fibrinous pericardial exudate The result of organisation is a scar it is a form of healing in which a minimum of new fibrous tissue is formed, with the requisite minimum of vessels to nourish it derived from the existing blood-vessels of the part In such a process in an artery the thrombus would be converted into a plug of fibrous tissue, with its own little circulation supplied by the arteries of the vessel wall and returning its blood to the veins of the vasa vasorum But is this what happens? No, we find a development of new blood passages and vessels within the thrombus, quite independent of the vasa vasorum And why is this? We have to remember that an artery has two sources of blood-supply, and that these are functionally independent The one is from the contained blood, and the other, to the major part of the wall, comes from adjacent small arteries but not directly from the main vessel The fact that these vasa vasorum come from smaller adjacent arteries means that the blood is supplied at a suitably reduced pressure It seems to me that these two divisions are functionally and anatomically independent, and that their territorial demarcation in medium muscular arteries corresponds to the internal elastic lamina I am not prepared to say whether this is an actual anatomical barrier or whether it merely corresponds to a physiological demarcation all I know is that it appears to exist

We know that intravascular occluding thrombi undergo this canalisation, and the evidence of histology is that these are through vessels which do not communicate with the vasa vasorum In fact if they did, and blood at high pressure from the lumen of a large artery were to pass directly into the small vessels in an organised thrombus, very abnormal hæmodynamic conditions would probably arise, and possibly the flow in the arteries of the vasa vasorum concerned might be reversed, and a direct arteriovenous communication develop with the veins of the arterial wall On the other hand, the exposure of these through channels to the full pressure of the blood in the occluded artery has the beneficial effect of distending them

I therefore conclude that the canalisation of a thrombus is a wholly different process from its organisation—different in its mode of development, the vessels involved, *and its purpose and effect* *The purpose of canalisation* is to restore as far as possible a through circulation, and this may be accomplished to various degrees Elsewhere I have illustrated the condition in canalised arteries and have described the stages of its development (Dible 1958)

The development of this new system of vessels within the boundary of the internal elastic lamina may take place from mesenchymal lining cells of the tunica intima but may also be contributed to by cells present in the circulating blood Such vessels are independent of the intrinsic circulation in the middle coat, and an important point in support of this argument is that the newly formed canalising vessels not only lie inside the internal elastic lamina but also are oriented in the direction of the artery's lumen, whereas the vessels in the middle coat of the artery's wall are oriented at right angles to these, and the two circulations do not communicate

But do the vasa vasorum play no part? I said earlier that they react to the presence of a thrombus, and this is so Their increased development, which is so obvious in fig 4, may well be due in part to the effect of the thrombus in cutting off the nutrition of the parts of the arterial wall nearest to the lumen, which are normally nourished by imbibition And I believe that their function is limited to this, at any rate in the beginning I do not deny that they may eventually penetrate the thrombus, but this appears to be a late change, associated with a break-up and disappearance of the internal elastic lamina such as we also find in the depths of an atheromatous plaque I think it possible that in this way the skeleton of the canalised thrombus may also receive a part of its blood-supply from the vasa vasorum (fig 5) and the rest from the canalised vessels Thus organisation and canalisation of a thrombus may coexist although the two circulations do not commingle This is simply a development of the

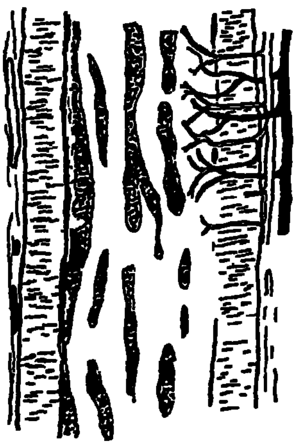

Fig 5—Hypothetical diagram of blood-supply from vasa vasorum to parts of framework of canalised thrombus

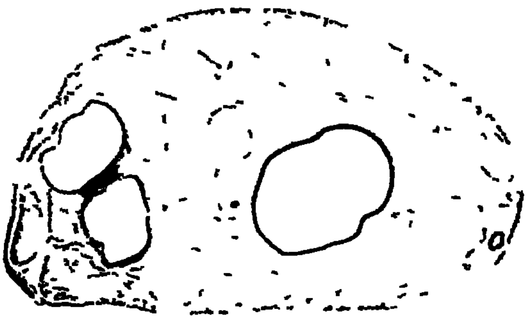

Fig 6—Dilated collateral arteries in sciatic nerve of man, aged 73, with senile atherosclerotic ischæmia (×9.5)

essential dual blood-supply of the arterial wall and appears to be its logical consequence.

Collateral Circulation

Where the arterial circulation is occluded, whether slowly or acutely, the blood tends to be diverted into other channels, known as collaterals. The collateral arteries are already formed vessels—so far as my investigations go, no new arteries are formed—and many of them are the named branches of the anatomists. Together they make up the arcade systems so characteristic of much of the arterial supply to the skin, muscles, and limbs. They are found in the subcutaneous tissues, in the intermuscular planes, on the periosteum, and in the nerve trunks, and I have produced evidence that the muscular vessels may play a part; indeed it seems possible that ischæmic claudication of the calf-muscles may be due to the bypassing of the functional muscular tissue, to enhance the blood-supply to the skin and subcutaneous tissues of the toes threatened with gangrene.

These collaterals, in fulfilling their function, dilate into thin-walled vessels. This surprised me when I first began to examine them, because I was obsessed with the idea, which I suppose many pathologists indulge, that hypertrophy of an artery meant thickening of its walls—a picture very familiar to us in hypertension. Now the condition of these thin-walled tubes is intriguing. It is not technically easy to compare them with similar vessels which are not acting as collaterals, but I have measured similar vessels in the normal and the enlarged states by utilising the arteries of the sciatic nerve (fig 6). From this it emerges that the circumference may be increased to as much as twelve times, but with this the thickness of the wall is reduced to half the normal size (fig 7). This leads to the interesting question of the change in the cells which make up the muscle wall. The great disproportion between circumference and thickness clearly rules out simple stretching. The nearest analogy is to the pregnant uterus. Kolliker (1853) states that, by the end of the sixth month, the length of the uterine muscle-cells increases from seven to eleven times, and their thickness from two to five times, with the result that they enlarge in all dimensions. It is generally accepted that they also increase in number. In the wall of the arteries which we are considering the condition is different because, though the vessel is dilated, its wall is thinned. But, since this thinning is less than it would be if the wall were merely stretched, either the cells must thicken or new cells must be added.

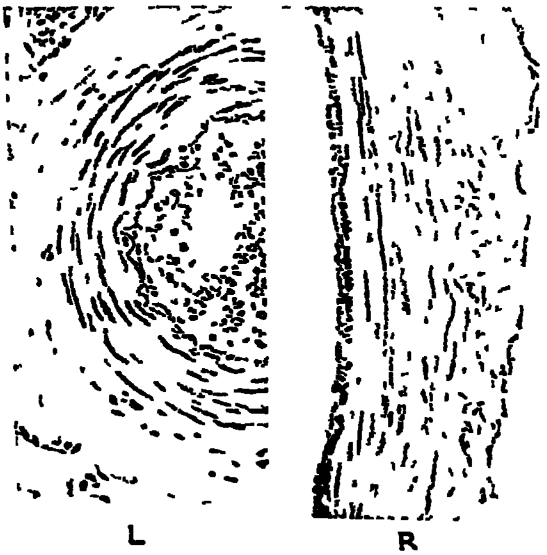

Fig 7—Normal sciatic (comites nervi) artery (L) compared with larger vessel in fig 6 at same magnification (R). Note relative thinning of muscular wall and of muscle nuclei in R (×150)

The number of cells in a cross-section of an artery may be estimated approximately by counting the nuclei, and in the case in point this shows some 500 cells in the section of the dilated artery compared to 200 in the corresponding control artery. What is the condition of the individual cells which causes the vessel to become thinner although their number is increased? If all the cells were to undergo the same change in size, and extra ones of the same size were simply packed in, the result could be cells twelve times the length and a fifth of the thickness of the normal. But this tremendous elongation seems unlikely, and it appears more reasonable to suppose that, like those of the uterus, they are perhaps six times the length but, unlike them, only about two-fifths of the normal thickness. This is very speculative because we do not know the extent to which they overlap each other. The exact change will have to be decided by maceration and dissection, but in any case the arterial muscle-cells must be much thinner in proportion to their length.

At this point I thought I might get some further information from the size of the nuclei, because the nuclei figured in enlarged uterine cells are definitely enlarged in all dimensions. Comparing the size of the muscle nuclei in different arteries I found (what I did not know before but might have deduced) that the size of the nucleus in these cells is related to the size of the artery. Large vessels have cells with large nuclei, and small vessels cells with small nuclei. I was therefore driven back to comparing sciatic arteries and found that the length of the nuclei in the cells I knew to be greatly elongated were not measurably greater than those in the control vessel. On the other hand, it was evident from inspection that they were decidedly thinner (fig 7), though the difference was difficult to measure. On taking mean figures and comparing the bulk of each nucleus, as the product of length and breadth, it appeared that the normal cell nucleus is about twice as bulky as the nucleus of the elongated cell. This rather surprising result seems to suggest that, in the maximally enlarged collateral, an element of atrophy may supervene.

It is obvious that the stimulus to this peculiar alteration in the arterial structure must be quite different from that which produces the thick-walled artery of hypertension. Wherein lies this difference? As regards hæmodynamics, there is an analogy with arteriovenous fistula, in which the artery discharging into the vein dilates, the reason seemingly being the lack of peripheral resistance, and the result an increased blood-flow Such factors may operate in the ischæmic limb For example, a terminal anterior branch of the peroneal artery normally inosculates with the anterior tibial and shares its tension at the point of junction But suppose, as often happens, the anterior tibial becomes occluded proximal to this anastomosis, the tension at and beyond the anastomosis is *immediately* reduced, such pressure as there is being maintained mainly by the flow of blood from the lateral plantar artery In chronic peripheral ischæmia from atherosclerosis the arteries of the foot are commonly patent and patulous, so such an occlusion as I have supposed would permit an excessive flow of blood from the peroneal branch into an area of abnormally low tension in the foot It is common for the posterior tibial artery also to be occluded, which would still further decrease the pressure in the vessels of the foot and favour an even greater flow of blood through the peroneal anastomosing branch, which would dilate to pass the amount of blood normally transmitted by these two larger channels as well as its own normal contribution

It therefore seems that an artery in a position to transmit blood against a lowered peripheral resistance will *dilate*, whereas one transmitting blood against an increased peripheral resistance will thicken

MODE OF ACTION OF
ORAL ANTIDIABETIC COMPOUNDS

KNUD LUNDBÆK
M D Copenhagen
PROFESSOR OF INTERNAL MEDICINE

KAI NIELSEN
M D Copenhagen
ASSISTANT PATHOLOGIST

OLE J RAFAELSEN
M D Copenhagen
ASSISTANT PHYSICIAN

From the Second Clinic of Internal Medicine and the Department of Pathology, Kommunehospitalet, Aarhus University School of Medicine, Aarhus, Denmark

IN the three years that have elapsed since the publication of the first papers on carbutamide (Achelis and Hardebeck 1955, Bertram et al 1955, Franke and Fuchs 1955) many clinical observations and experimental results have been published dealing with various possibilities of site and mechanism of the hypoglycæmic effect of this compound and other " oral antidiabetic drugs "

We describe here the situation as we see it today, emphasising beforehand that a full understanding of the details of this mechanism has, of course, not been obtained—not even a high degree of certainty about its broad outline

Action on or via Endocrine Glands

In the treatment of diabetes mellitus the effect of the oral antidiabetic drugs is similar, in many ways, to that of giving small doses of insulin There is not, however, sufficient evidence that these drugs provoke an increase in the production and delivery of insulin from the cells of the pancreatic islets

In experiments on animals conflicting results have obtained from the study of islet-cell volume (Ashwor and Haist 1956, Kinash 1957) as well as from investigatio of the hypoglycæmic effect of small amounts of an diabetic compounds injected directly into the pancreatic duodenal artery (Loubatières 1946, Colwell et al 195 Houssay et al 1957a and b)

Pozza et al (1956) made cross-circulation experimen with carbutamide in eight pairs of dogs The blood sugar level fell in the recipient dogs, which receive blood from the pancreatic vein of the carbutamide treated donor dog, the blood-sugar level did not fall dogs connected to the mesenteric vein of donor dog However, only average figures of changes in blood-sug levels are given, and this kind of experiment does no seem to have been repeated by other workers

Some workers have described slight and inconstan changes in the staining reactions of the beta cells animals given oral antidiabetic compounds (Loubatière 1955, Kracht and Rausch-Stroomann 1956), but in th rat, at any rate, we feel convinced that no change take place in either the shape or the granulation of the insulin producing cells (Lundbæk and Nielsen 1958) (see table)

Another kind of " insulin action " was envisaged b Mirsky, who reported that the oral antidiabetic com pounds decreased the activity of insulinase in the liver of rats (Mirsky et al 1956, 1957) Evidently a decreas in the activity of an insulin-splitting enzyme would b equivalent to an increase in the activity of circulatin endogenous insulin In concentrations comparable t those eliciting a fall of the blood-sugar level this effect o insulinase activity was, however, very slight and perhap even dubious, and other workers have been unable t confirm Mirsky's hypothesis (Williams and Tucker 1956 Vaughan 1956, Cox et al 1956, Williams 1957)

The breakdown of insulin has also been studied with radioactive insulin Tolbutamide did not prolong th half-life of injected insulin labelled with ^{131}I (Wick et al 1957, Berson et al 1957, Volk et al 1957)

Even if neither the production nor the amount o circulating insulin were increased by the oral antidiabetic drugs, insulin action might still be enhanced by inhibition of one of the anti-insulin hormones Such a mechanism was one of the first to be proposed to explain the hypoglycæmic effect of these compounds Several investigators reported that 2-(*p*-aminobenzene-sulphamido)-5-isopropyl-thiodiazole (I P T D), carbutamide, and tolbutamide severely damaged the pancreatic alpha cells, thought to be the most important source of glucagon (von Holt et al 1956, Ferner and Runge 1956) Other workers found no damage to the alpha cells after administration of sulphonylureas (Volk et al 1956, Goldner et al 1957),

HISTOLOGICAL CHANGES IN PANCREATIC ALPHA AND BETA CELLS OF RATS AFTER ADMINISTRATION OF VARIOUS ANTIDIABETIC DRUGS
(From Lundbæk and Nielsen 1958)

Drug	No of animals	No of controls	Total dose (mg)	Histological changes of	
				Alpha cells	Beta cells
Carbutamide	75	29	75–3375	0	0
Tolbutamide	44	11	,,	0	0
I P T D	28	9		0	0
Synthalin A	10	3	20	+ → +	0
Total	*157*	52	—	—	—

nd our experiments with short- and long-term administration of large and small amounts of carbutamide, olbutamide, and IPTD in rats were completely negative Lundbæk and Nielsen 1958) (see table)

A hypoglycæmic effect due to depression of other antinsulin hormones seems to be excluded by the fact that he antidiabetic compounds are equally active or even nore active in animals deprived of the hypophysis, the drenal glands, the thyroid gland, the parathyroid glands, r the gonads (Loubatieres 1955, Houssay and Penhos 956, Lang and Sherry 1956)

Finally, if the hypoglycæmic action of the antidiabetic ompounds were an "insulin-like" effect—directly or indirectly—it would be expected to be accompanied regularly by hypophosphatæmia It has been reported that, in healthy people, intravenous tolbutamide decreases the amount of inorganic phosphate in the serum (Goetz et al 1956, Frawley et al 1957), but no change in the phosphate curve was found in diabetics in whom treatment with carbutamide or with tolbutamide significantly increased the tolerance of intravenous glucose, calculated on the blood-sugar values observed or on the "excess blood sugar" (Eskjær Jensen et al 1958) (fig 1)

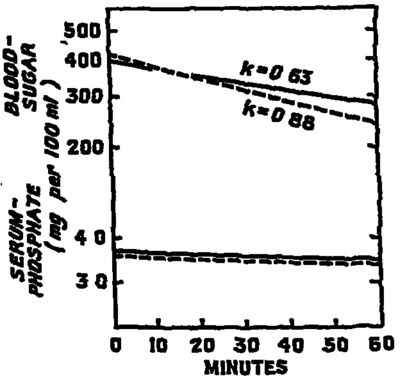

Fig 1—Average curves of intravenous glucose-tolerance tests and serum inorganic phosphate before (continuous line) and during (interrupted line) treatment with antidiabetic drug (Eskjær Jensen et al 1958)

On the whole it seems to us that, at present, the hypoglycæmic effect of the oral antidiabetic drugs has not been shown to be due either to augmentation of insulin action or to inhibition of the actino of the antidiabetic hormones

Site of Action

Intestines

In rats given large doses of carbutamide orally in short-time experiments Friedlich et al (1956) found a decreased intestinal absorption of glucose In human beings treated with tolbutamide there is no such effect (Frawley et al 1957), and it is well known that the antidiabetic compounds are very active when given intravenously

Liver

Several workers have found that the oral antidiabetic compounds influence the output of glucose from the liver Anderson et al (1956, 1957), who catheterised the hepatic vein in tolbutamide-treated dogs, observed a pronounced inhibition of the release of glucose from the liver This finding was confirmed by Schambye and Tarding (1957), and Kibler and Gordon (1956) observed the same phenomenon in diabetic patients

A hepatic effect is also obvious from the fact that the administration of oral antidiabetic compounds increases the amount of glycogen in the liver (Bänder and Scholz 1956, Tyberghein et al 1956, Miller and Dulin 1956)

The action on the liver has been studied further in vitro The production of glucose in liver slices has been reported to be reduced in the presence of antidiabetic compounds (Clarke et al 1956, Frawley et al 1957), but other workers have found either no decrease or a decrease only at excessively high concentrations (Ashmore et al 1956, 1957, Berthet et al 1956) Glucose-6-phosphatase activity is inhibited by carbutamide and tolbutamide, but also only in very high concentrations (Ashmore et al 1956, 1957, Tyberghein et al 1956, Hawkins et al 1956, Haist et al 1957, Berthet et al 1956, Kuether et al 1956, 1957)

It thus seems that, although the precise mode of action in the liver has not yet been elucidated, the inhibitory action of these compounds on the output of glucose from the liver may be accepted On the other hand, it is now known that the presence of the liver is no prerequisite for the hypoglycæmic effect of the oral antidiabetic compounds A fall of the blood-sugar level is seen in hepatectomised animals given tolbutamide or N'-β-phenethylformamidinyliminourea (Phenethyl-diguanide, DBI) (Dulin and Johnston 1957, Williams et al 1957)

At the Periphery

The possibility of an action on the uptake of glucose at the periphery, has been less intensely explored, probably because some of the earlier studies were regarded as rather definitive proofs against such a mechanism

In perfusion experiments with eviscerated animals no effect of carbutamide or of tolbutamide was found by Lang and Sherry (1956), Fritz et al (1956), and Wick et al (1956) Investigations of the arteriovenous blood-sugar difference after the administration of antidiabetic drugs in man have given conflicting results (Goetz et al 1956, Recant and Fischer 1957)

The Gemmill method, by which the uptake of glucose and the synthesis of glycogen in the isolated rat diaphragm are determined in vitro, should be a useful tool for elucidating this problem Clarke et al (1956), Cahill et al (1957), and Recant and Fischer (1957) reported that carbutamide and tolbutamide had no effect on the uptake of glucose from the medium, but DBI increases the uptake of glucose by the rat diaphragm (Williams et al 1957)

In our laboratory a clearly increased uptake of glucose was found with carbutamide as well as with tolbutamide and IPTD, also in concentrations comparable to the levels achieved in the blood when these drugs are used in patients (Rafaelsen 1958) (fig 2) We have also confirmed the finding of Williams et al (1957) that DBI has a strong effect on the uptake of glucose (fig 2) The reason for the failure of earlier workers to observe the relatively mild effect of carbutamide and of tolbutamide on the uptake of glucose by isolated muscle is not quite clear Most studies have, however, included only few experiments, and in the largest one (Recant and Fischer 1957) the standard deviation of the result is surprisingly high

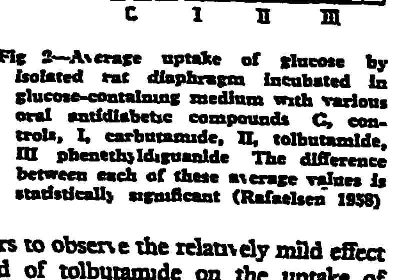

Fig 2—Average uptake of glucose by isolated rat diaphragm incubated in glucose-containing medium with various oral antidiabetic compounds C, controls, I, carbutamide, II, tolbutamide, III phenethyldiguanide The difference between each of these average values is statistically significant (Rafaelsen 1958)

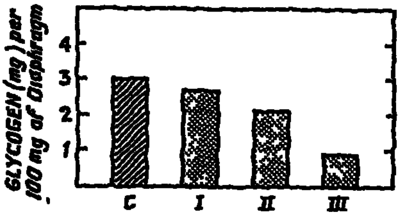

Fig 3—Average glycogen content of isolated rat diaphragm after incubation in glucose-containing medium with various oral antidiabetic compounds C, I, II, and III as in fig 3 III is significantly lower than C, I, and II (Rafaelsen 1958)

The amount of glycogen in muscle is not increased either by carbutamide or by tolbutamide (Rafaelsen 1958), it is even decreased by D B I (Williams et al 1957, Rafaelsen 1958) (fig 3) This finding suggests that the effect of the antidiabetic compounds on the carbohydrate *metabolism of muscle differs from that of insulin*, which in concentrations above 10^{-3} I U per ml always induces the accumulation of glycogen in the isolated rat diaphragm

On the other hand, we have found that these drugs influence the uptake of galactose and fructose without affecting that of *d*-arabinose, just as insulin does (fig 4)

The details of the mechanism of this peripheral action on muscle are under investigation at present—especially the question whether it works by either of the two pathways of glucose metabolism in muscle recently described by Shaw and Stadie (1957)

Experiments in which the effect of oral antidiabetic compounds on the formation of $^{14}CO_2$ from glucose labelled with ^{14}C was estimated have been published by several laboratories Wick et al (1956) and Williams et al (1957) found no demonstrable effect, but Miller et al (1957) and Rice (1957) reported a rather pronounced increase in the combustion of glucose, measured by this technique

It therefore seems that enhancement of the uptake of glucose at the periphery is one of the modes of action of the oral antidiabetic drugs Both the hypoglycæmia following the *administration* of these compounds in hepatectomised animals and the result obtained with isolated muscle point in this direction

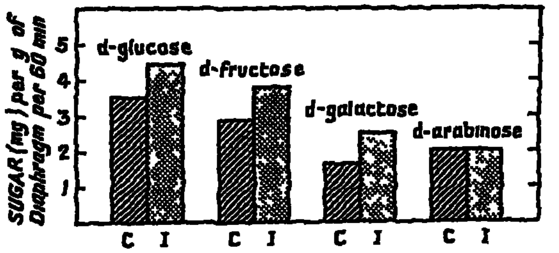

Fig 4—Average uptake of various sugars by isolated rat diaphragm incubated in media containing these sugars and carbutamide C and I as in fig 3 Increased uptake of *d*-glucose, *d*-fructose, and *d*-galactose due to carbutamide are statistically significant (Rafaelsen 1958)

Prerequisites for Hypoglycæmic Effect of Antidiabetic Drugs

The German workers who introduced carbutamide noted that it had no effect, or only a very slight effect, on patients with severe diabetes mellitus (Franke and Fuchs 1955, Bertram et al 1955) Most workers have found that I P T D, carbutamide, and tolbutamide are without effect in animals with severe alloxan diabetes (Loubatières 1946, Achelis and Hardebeck 1955, Lang and Sherry 1956, Bänder and Scholz 1956)

Mirsky et al (1957) compared the hypoglycæmic effect of tolbutamide on alloxanised rabbits with various degrees of hyperglycæmia In rabbits with only mild hyperglycæmia an antidiabetic effect could be obtained, but rabbits with very high blood-sugar levels did not respond

Other workers have emphasised that the action of insulin seems to be potentiated by antidiabetic drugs when carbutamide or tolbutamide is given to pancreatectomised dogs receiving constant amounts of insulin, the blood-sugar level is lowered further (Sirek and Sirek 1956, Houssay et al 1957, Ricketts et al 1957)

These clinical observations and experimental results have been regarded by many workers as evidence that the presence of insulin, either from functioning beta cells or as administered insulin, is a prerequisite for the hypoglycæmic action of these compounds

D B I, the latest oral antidiabetic drug to be discovered, does, however, produce hypoglycæmia in young patients with severe diabetes mellitus and in animals with severe alloxan diabetes (Williams et al 1957), and in our preliminary in-vitro experiments with diaphragms of alloxanised rats a statistically significant increase in the uptake of glucose was found even with carbutamide (Lundbæk and Rafaelsen 1958)

Finally, a clearcut fall of the blood-sugar level can be obtained in the hypophysectomised pancreatectomised dog (Houssay et al 1957a and b) Such dogs have no source of insulin, but their blood-sugar level is close to normal

Perhaps the results obtained in different degrees of severity of clinical diabetes mellitus and of experimental diabetes in animals should be formulated not in terms of the presence or the absence of insulin in the organism but in terms of the degree of severity of the diabetes It seems that the milder of the compounds—carbutamide and tolbutamide—act on carbohydrate metabolism to produce demonstrable effects when, and only when, the endocrine balance is normal or rather close to normal, not when a profound state of disequilibrium obtains D B I has a stronger effect and can normalise a more pronounced diabetic aberration of metabolism

Summary

On present evidence the hypoglycæmic effect of the oral antidiabetic drugs cannot be explained by interference with the endocrine balance of the organism

Among the modes of action of these compounds inhibition of the output of glucose by the liver and enhancement of the uptake of glucose at the periphery seem to be acceptable The detail of the changes in enzyme activities probably involved in the hepatic and peripheral effects have not been elucidated

It is suggested that the hypoglycæmic effect of the oral antidiabetic compounds is determined not by the presence or absence of insulin but by the degree of diabetic aberration of metabolism

HEINZ-BODY ANÆMIA DUE TO SALICYLAZOSULPHAPYRIDINE

SALICYLAZOSULPHAPYRIDINE was introduced by Svartz (1942) for treating ulcerative colitis Taken by mouth it is absorbed from the gut and is deposited in connective tissue, including that in the bowel, where aminosalicylic acid and sulphapyridine are gradually liberated Free sulphapyridine can be detected in the blood

It has been extensively used in the Scandinavian countries (Svartz 1948, 1954, 1956, Lagercrantz 1949, 1955), and has been used in America under the names of 'Azopyrin' and 'Asulfidine' (Morrison 1952, 1953) Bargen (1955), who has a very large experience of ulcerative colitis, states that "the most valuable drug that has been introduced for the treatment of ulcerative colitis in the years that I have been interested in the problem is salicylazosulfapyridine"

In this country the drug has been available only for the past three years, under the name 'Salazopyrin' Since it seems possible that its use will increase, it is necessary to be aware of its toxic effects Nausea or vomiting develops in 1 patient in about 5 or 6 treated with salazopyrin Less common are skin rashes, drug fever, and joint reactions Serious toxic reactions are said to be rare, the principal one being neutropenia going on to agranulocytosis

After seeing 2 patients (cases 1 and 2 below) in whom toxic anæmia with Heinz-body formation developed during salazopyrin therapy, we began to make regular examinations for Heinz bodies in all patients receiving the drug, and a further case has since been discovered (case 3)

Technical Methods

Demonstration of Heinz Bodies

Method I (wet preparation).—A few drops of blood from a finger-prick are taken into about double their volume of 0·5% methyl-violet in isotonic saline solution (The stain solution must be filtered before use.) After the blood has stood for a few minutes, a drop of it is examined under a cover-slip with the oil-immersion objective

Method II (permanent preparation).—A few drops of blood from a finger-prick are taken into isotonic saline solution containing 0 5% sodium citrate. The tube is centrifuged until the cells are deposited, and the supernatant fluid is poured off The red cells are resuspended in isotonic saline solution containing 0·5% methyl-violet (This solution must be filtered immediately before use.) The tube is centrifuged again, and films are made from the deposited red cells with the least possible delay These are air-dried and mounted without any counterstain

By either of the above methods Heinz bodies are shown as darkly stained discrete particles in the almost colourless red cells

Reticulum is visible as a diffuse violet mottling or speckling

Other Methods

All other hæmatological techniques used were those recommended by Dacie (1956)

Case-reports

Case 1.—A man, aged 28, was put on salazopyrin therapy on Aug 23, 1956, for severe ulcerative colitis He had a past

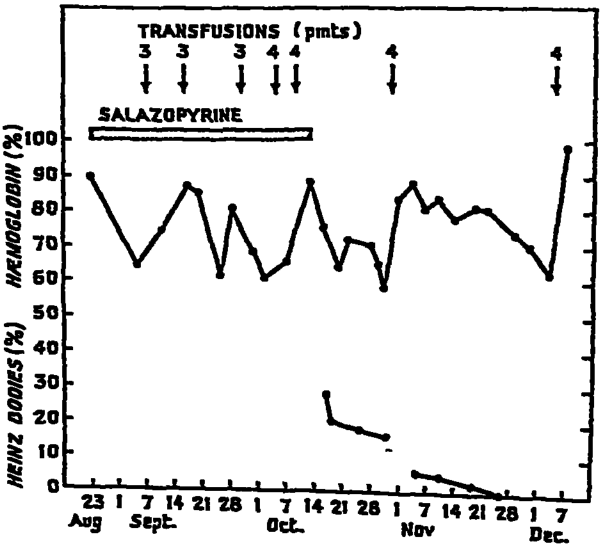

Fig 1—Treatment and course in case 1

history of tuberculosis, beginning with a pleural effusion in May, 1949, and ending with antituberculous treatment in 1951 and 1952 for caries of the spine His first episode of diarrhœa was in January, 1956, lasting only three days, and further episodes occurred in March and in May of the same year From June, 1956, he had continuous abdominal discomfort and increasingly loose bloodstained motions containing mucus An inflamed and ulcerated mucosa was seen on sigmoidoscopy By August, 1956, he was having upwards of twenty-five motions daily and required repeated transfusions to maintain his hæmoglobin

Salazopyrin therapy was begun on Aug 23, 1956 The initial dose of 2 0 g q d s was reduced after five days to 1 0 g q d s At the same time the patient was given corticotrophin gel 80 units daily for twenty-one days, followed by 40 units daily for twenty-one days, and (because of the history of tuberculosis) intramuscular streptomycin 0 5 g b d

Hæmatology —After ten days the patient became less ill and during the next month the diarrhœa was considerably improved and obvious blood ceased to be present in the stools, but increasingly frequent blood-transfusions were needed to maintain a satisfactory level of hæmoglobin (fig 1) On Oct 3, 1956, and again on Oct 9, 1956, spherocytes and fragmented red cells were seen in blood-films, and the reticulocytes were 9 6% and 5 0%, red-cell fragility and plasma-bilirubin were normal The Coombs test was negative, and there was no methæmoglobinæmia On Oct 13, 1956, the salazopyrin was discontinued because it was thought to be responsible for the anæmia Heinz bodies were first looked for on Oct 15, 1956, and were found in 30% of the red cells Over the next four weeks the percentage of affected red cells diminished steadily and they finally disappeared (fig 1) The fragmented cells also disappeared, and only two more blood-transfusions were necessary before the patient was discharged from hospital. When last seen the patient was at full work, with hæmoglobin 105%, and symptom-free

The main hæmatological data are set out in table I

Case 2 —A woman aged 65, was treated with salazopyrin for a malabsorption syndrome due to an ileocolic fistula After having a perforated appendix in 1936 she had several operations for intestinal obstruction, including an anastomosis and a resection of a segment of bowel In 1942 she began to have diarrhœa with loose bulky offensive stools From 1947 onwards she was treated for macrocytic anæmia and steatorrhœa

Salazopyrin therapy —In November, 1956, the patient was readmitted under Prof G W Pickering Barium studies showed an ileocolic fistula, and, to reduce bacterial colonisation of the small intestine, salazopyrin was given in a dosage of 2 g t d s , beginning on Dec 2, 1956

Hæmatology —Before salazopyrin was given the patient had a normal blood picture On Dec 17, 1956, her hæmoglobin level was 78%, and the reticulocyte-count was 4 5% The reticulocyte preparation showed large inclusion bodies in 95% of the red cells, and these were shown to be Heinz bodies (fig 2 shows the appearance next day) A blood film showed much fragmentation and distortion of the red cells The plasma-bilirubin level was 0 9 mg per 100 ml , and a little methæmoglobin was found The fragility of the red cells was normal, and a direct Coombs test was negative

Salazopyrin was immediately discontinued The hæmoglobin level, which had fallen to 58% by Dec 19, 1956, began to rise spontaneously, while the Heinz bodies showed a steady fall (fig 3) Five weeks after the salazopyrin had been discontinued the blood-picture was normal

The main hæmatological data are given in table II

Case 3 —A man, aged 61, was given salazopyrin for ulcerative colitis On starting medical treatment he was having twenty-five motions daily and had pyrexia and tachycardia

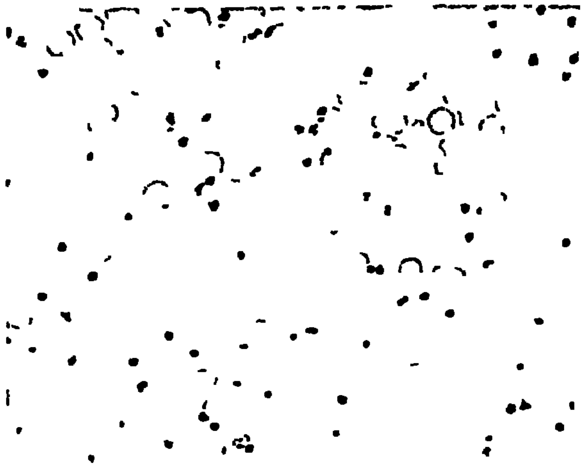

Fig 2—Blood of case 2 stained supravitally for Heinz bodies

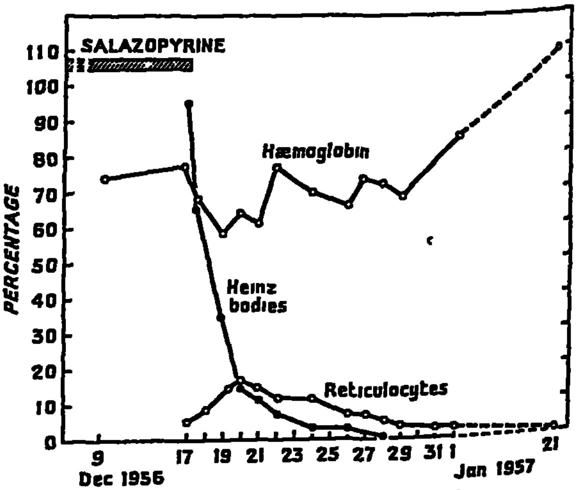

Fig 3—Treatment and course in case 2.

Under treatment with intramuscular corticotrophin gel 80 units daily and blood-transfusions the diarrhœa lessened and the stools no longer contained obvious blood On Feb 22, 1957 corticotrophin was withheld and the patient was put on to salazopyrin 1·0 g q d s He required a blood-transfusion of 4 pints on Feb 26, and again on March 12, 1957, and March 22, 1957

Heinz bodies were first found on March 25, 1957, and were present in 26% of the red cells Salazopyrin was immediately discontinued, and thereafter the percentage of cells containing Heinz bodies decreased steadily, reaching very low levels in a fortnight No further transfusions were necessary On discharge from hospital the patient was symptom-free

The main hæmatological data are set out in table III

Discussion

With few exceptions the presence of large numbers of Heinz bodies points to chemical poisoning Among numerous toxic substances which cause Heinz bodies to form are benzene derivatives with amino- or nitro-groups such as phenylhydrazine, phenacetin, and the sulphonamides (Fertman and Fertman 1955) In the last group sulphanilamide and sulphapyridine are particularly active. Probably many of the cases of anæmia reported as being due to sulphonamides (Wood 1938) were of this type, but until the publications of Moeschlin (1940, 1941) the characteristic inclusion bodies were not sought for

In the present three cases salazopyrin was the only drug used which forms Heinz bodies Withdrawal of the salazopyrin was followed by an immediate fall in the Heinz-body count and an arrest of the hæmolytic anæmia It therefore seems certain that the anæmia was due to salazopyrin intoxication.

The hæmolytic anæmia associated with Heinz bodies is principally determined by the diminished life-span of the affected red cells Reported figures for the rate of disappearance of Heinz bodies after cessation of drug treatment lie between four days (Markoff 1943) and thirty days (Gasser 1953) The Heinz bodies in the three present cases had disappeared after forty-nine, eleven, and fourteen days Possibly the Heinz bodies may be extruded during the life of the red cell, if not, the shape of the disappearance curves indicates either that the affected cells are randomly destroyed or that different cells in the same sample have very different life-spans according to number of Heinz bodies

The anæmia is probably aggravated by the degradation of hæmoglobin in the affected red cells Chemical studies and electron-microscopy have shown that Heinz bodies are very dense and contain a large amount of iron (Rozsa and Spicer 1953), and it is generally agreed that they are derived from hæmoglobin The facts that they can be produced in red blood-cells by numerous chemical agents in vitro and that they are seldom, if ever, found in reticulocytes or in nucleated red cells indicate that the inclusions are formed in vivo in the circulating mature red cells Methæmoglobinæmia and other abnormal pigments sometimes occur in these anæmias (Dacie 1954), and methæmoglobin was found in case 2

In view of our experience with these cases we have made it a routine to examine the blood for Heinz bodies in all patients receiving salazopyrin Since Heinz bodies are invisible in Romanowsky-stained blood-films, it is essential that they should be looked for specially Hæmolytic anæmia is easily overlooked in a patient with ulcerative colitis who is losing blood If such a patient is being treated with salazopyrin, the special examination for Heinz bodies provides an easy means of showing when the anæmia is due not to the disease but to the treatment.

Summary

Three cases of Heinz-body anæmia due to the use of salicylazosulphapyridine (' Salazopyrin ') are reported

The blood of patients treated with salazopyrin and other sulphonamides should be regularly examined for Heinz bodies

We are grateful to Dr A H T Robb-Smith, Dr R G Macfarlane, and Prof L J Witts for helpful criticism and to Prof Sir George Pickering for permission to include case 2

ADDENDUM

Since this article was written, another case of Heinz-body anæmia has occurred in a patient receiving salicylazosulphapyridine We have now made regular observations on 32 patients with ulcerative colitis being treated with this drug, so that this case, together with case 3, shows that the complication is fairly common

SERUM-PROTEINS IN PATIENTS WITH NON-HÆMOLYTIC TRANSFUSION REACTIONS

A Polak
M D Zagreb
OF THE BLOOD-TRANSFUSION CENTRE, ZAGREB, YUGOSLAVIA

M Fišer-Herman
Ph D Vienna
OF THE INSTITUTE OF CLINICAL CHEMISTRY, ZAGREB

Though *there are more and more blood-transfusions*, hæmolytic reactions are rare, because they are eliminated by adequate compatibility tests, and the perils of contamination are practically excluded by expert preparation and handling of the blood and instruments On the other hand, troubles are cropping up which we cannot explain in spite of all precautions some patients react unfavourably to transfusions which are correctly administered These troubles may arise during or shortly after the transfusion Most frequently they present with symptoms of fever and allergy—shivering, laboured breathing, cyanosis, low blood-pressure, rashes, and sometimes shock Such conditions are always distressing and may be dangerous

Symptoms of this kind are seen chiefly in exhausted patients with hypoproteinæmia or with dysproteinæmia

MEAN LEVELS OF TOTAL PROTEIN AND OF ELECTROPHORETIC FRACTIONS IN SERUM (G PER 100 ML)

Group	No of persons	Total protein	Albumin	Globulin				A/G ratio
				α_1	α_2	β	γ	
Healthy donors	18	7 14	4 02	0 42	0 56	0 79	1 36	1 29
Non-reactors	34	7 2	3 46	0 36	0 77	0 74	1 89	1 00
Reactors	24	6 2	2 72	0 36	0 67	0 75	1 73	0 88

Such patients can usually be given safely either blood partially freed from plasma, or (better still), washed erythrocytes suspended in saline solution Dameshek and Neber (1950) described transfusion reactions caused by some constituents of plasma, and Crosby and Stefanini (1952) published similar cases Possibly, therefore, non-hæmolytic reactions might be induced by the composition of the patient's plasma and/or by that of the transfused blood

So far no reliable method has been developed by which we can investigate the compatibility of plasma-proteins as a routine in the same way as we test the compatibility of the patient's and donor's plasma and erythrocytes We take blood for transfusion from "healthy donors" without knowing much about the composition of their plasma-proteins We still use these proteins in transfusions as we formerly used the erythrocytes of "universal donors," assuming that the composition of the donor's plasma is almost always constant On the other hand, we know that the recipient's plasma is very often abnormal, and methods in current use make it possible to establish important individual differences in the plasma-proteins of our patients

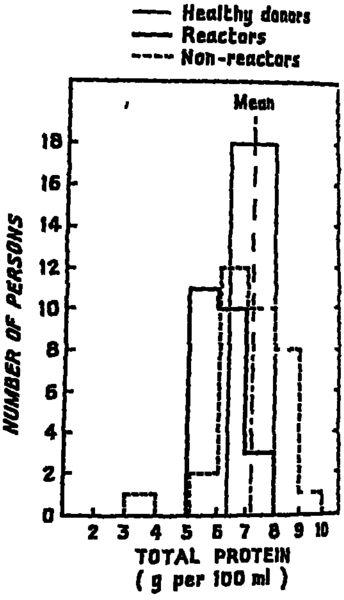

Fig 1—Distribution of levels of total proteins in serum

We accordingly investigated the serum-proteins of patients who had had non-hæmolytic reactions to transfusion We tried to discover (1) whether there were significant differences between the serum-proteins of patients who had reacted and those who had not, (2) whether examination of the serum-proteins of a patient could indicate hypersensitivity to whole blood, and (3) whether such reactions could be avoided by transfusing sensitive patients with blood partially or totally freed from plasma

Materials and Methods

At our request, hospitals sent us samples of fresh blood from every patient who had reacted unfavourably to a blood-transfusion, as well as from many patients who had not so reacted, together with all available information about the diagnosis, clinical course, and previous blood-transfusions Serum was taken from these samples and analysed the same morning All samples which came from patients who had had hæmolytic reactions to transfusion, and all hæmolytic sera, were discarded

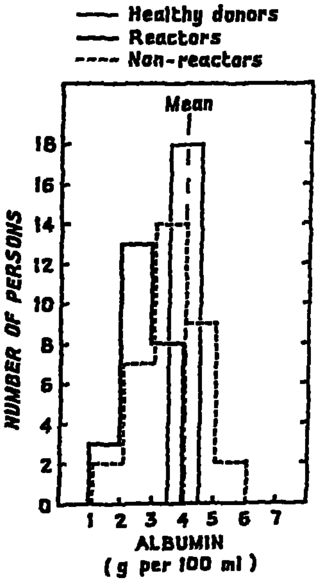

Fig 2—Distribution of serum-albumin levels

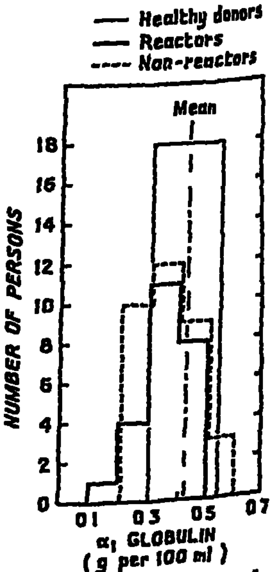

Fig 3—Distribution of α_1-globulin levels in serum

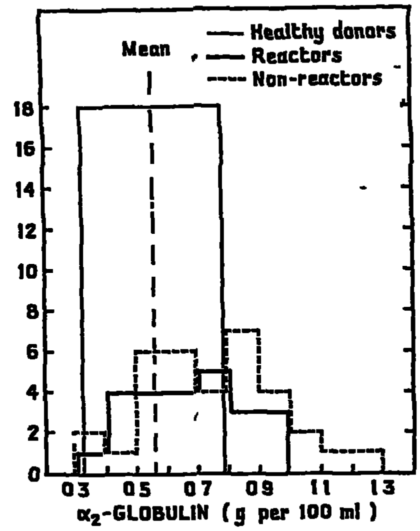

Fig 4—Distribution of α_2-globulin levels in serum

Laboratory analysis consisted in determination of total protein by the biuret method of Wolfson et al (1948) and of paper electrophoresis carried out horizontally in a closed chamber in M/20 phosphate buffer pH 8 9 The dried strips were stained with bromophenol blue and percentages of fractions estimated by cutting out, elution, and photometry These values were converted into absolute concentrations by multiplication by the factor for total protein

This procedure was applied to the sera of a random group of healthy blood-donors, a random group of recipients of blood-transfusions who had had no symptoms of reaction, and all those patients whose unfavourable reaction to blood-transfusions could not be ascribed either to faulty matching of blood-groups or factors or to contamination

Results

The mean levels of total protein and electrophoretic fractions in the serum of healthy donors, patients who had no reactions, and those who had non-hæmolytic reactions are shown in the accompanying table and their distribution in figs 1–6

It is evident that, in our groups, non-hæmolytic reactions to blood-transfusions were commoner in patients who had low serum-protein levels, especially low serum-albumin levels As regards β-globulins, we found no significant difference between recipients who reacted and those who did not α_2-globulin levels were more often raised in non-reactors than in reactors, whereas α_1-globulin levels were more often subnormal in non-reactors than in reactors

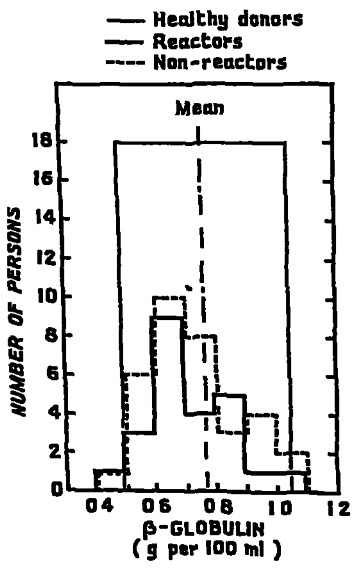

Fig 5—Distribution of β-globulin levels in serum

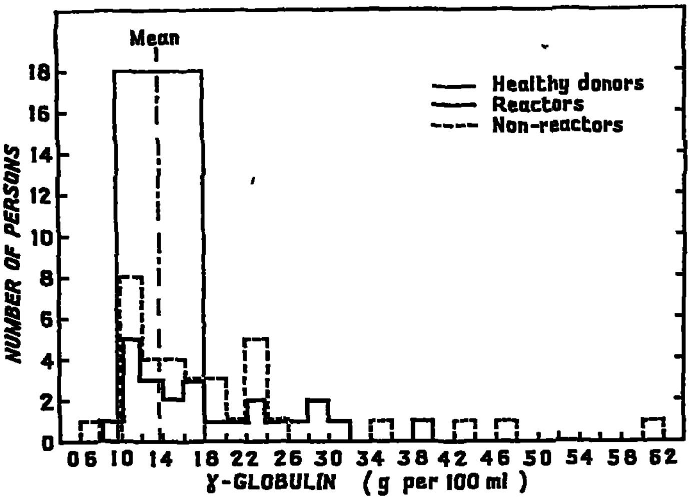

Fig 6—Distribution of γ-globulin levels in serum

In both groups some patients had hypergammaglobulinæmia, but, in our experience, hypergammaglobulinæmia does not contribute to the development of transfusion reactions On the contrary, patients with extreme hypergammaglobulinæmia (2 with kala-azar, 1 with leukæmia, 1 undiagnosed) took blood-transfusions very well

The albumin/globulin ratio in the serum was in many patients lower than normal, the means (see table) were below normal in both groups of recipients, being lower in the reactors than in the non-reactors In most cases the low ratio was not due to hyperglobulinæmia but to hypoalbuminæmia

Conclusions

It seems to us, that, when transfusion is not very urgent, it might be useful to analyse the patient's serum-proteins Several patients who reacted unfavourably to whole blood took washed erythrocytes very well These patients had low serum-protein levels, especially a low serum-albumin Patients with such abnormalities in plasma-proteins should be given blood practically free from plasma Such blood should always be given to patients who have had a non-hæmolytic reaction to a previous blood-transfusion

Washed erythrocytes, of course, have not the biological value of whole blood, they can still be useful to a weakened organism By giving them one can spare the recipient's plasma-proteins, which are used for synthesising hæmoglobin (Whipple 1948)

We claim that this treatment is more physiological than the routine use of antiallergic and other drugs to prevent transfusion reactions

When we had almost completed our investigation, we found that Wigand (1957), Moller (1957), and Kryger (1957) had also found that non-hæmolytic reactions to blood-transfusion were commoner in patients with abnormal serum-protein levels

Summary

The serum levels of total protein and electrophoretic protein fractions were estimated (a) in patients who had had (non-hæmolytic) reactions to blood-transfusion, (2) in healthy blood-donors, and (3) in patients who had taken blood-transfusion well

Subnormal total-protein levels—and especially a low serum-albumin—were found most often in the patients who had reacted badly to blood-transfusion

It is recommended that, in non-urgent cases the patient's serum-proteins should be determined before transfusion

Where the serum-protein, and especially the serum-albumin, is low, the patient should be given washed erythrocytes instead of whole blood

TOTAL GASTRECTOMY FOR BENIGN PEPTIC ULCER

J A Balint
B A , M B Cantab , M R C P
MEDICAL REGISTRAR, CHARING CROSS HOSPITAL, LONDON, W C 2

J W P Gummer
M S Lond , F R C S
ASSISTANT SURGEON, CENTRAL MIDDLESEX HOSPITAL, LONDON, N W 10

TOTAL gastrectomy is rightly regarded as a serious undertaking and is usually reserved for treating carcinoma of the stomach Balint et al (1957) suggest, however, that total gastrectomy "should be done in any patient in whom anastomotic ulcers continue to recur after adequate vagotomy and partial gastrectomy" Their 3 patients who underwent total gastrectomy had moderately good health afterwards

We review here the experience of 12 patients who underwent total gastrectomy for benign peptic ulcer at the Central Middlesex Hospital

Case 1 —A man, aged 42, was admitted on Oct 11, 1951, with nine years' history of typical ulcer dyspepsia, which had become more severe for eight months before admission, with nausea, vomiting, anorexia, and a loss of weight of 21 lb A barium meal showed an apparently malignant ulcer on the lesser curve of the stomach and involving the antrum At gastroscopy, however, the ulcer appeared to be simple At operation on Nov 24, 1951, an extensive ulcer in the middle third of the lesser curve was found, with many enlarged glands The appearances suggested carcinoma, and a total gastrectomy with end-to-end œsophago-duodenostomy (fig 1) was done Histological examination proved the ulcer to be benign

Postoperative progress —The patient's preoperative weight of 8 st 13 lb had decreased to 7 st 8 lb when he was discharged from hospital After this he gained weight despite the fact that, on radiological examination, barium reached the terminal ileum five minutes after it had been swallowed In August, 1952, he weighed 7 st 11 lb He continued to gain weight and by February, 1953, had reached 8 st 2 lb and could eat a good diet His weight remained steady until February, 1956, when it decreased to 7 st 12 lb and a small lesion was noted in his right lung but was thought to b quiescent By January, 1957, his weight had decreased to 6 st 2 l and tubercle bacilli were found in his sputum He is still receiv antituberculous chemotherapy and is responding slowly Treatment is complicated by the development of streptomycin sensitivity H haemoglobin is 82%.

Summary —A man, aged 42, underwent total gastrectomy with œsophago-duodenal anastomosis for what was histologi cally proved to be a benign ulcer His subsequent course was satisfactory, with gain in weight and a fair appetite, until th development of pulmonary tuberculosis four years and four months after the operation

Case 2 —A woman, aged 47, had a severe hæmatemesis from a duodenal ulcer in 1946 A Polya-type partial gastrectomy was do in 1947 because of continuing ulcer pain. Her symptoms soo returned, and an anastomotic ulcer was found radiologically in 194 In March, 1950, laparotomy was done after a further hæmatemesis, when an anastomotic ulcer and a pancreatic adenoma were found No resection was done at this operation, but in October, 1950, the patient was admitted with a view to a further partial gastrectomy for severe ulcer pain, but she developed a volvulus of the cæcum and underwent a right hemicolectomy, and the partial gastrectomy was done later She had to be readmitted after a hæmatemesis in June, 1951, when another anastomotic ulcer was found She was treated medically A melæna in April, 1952, was treated at home, but in September, 1953, admission to hospital was again necessary becaus of severe hæmatemesis A total gastrectomy was done with an œsophageal anastomosis to the side of a Roux loop of jejunum (fig 5) The patient was discharged after a stormy convalescence due to a subphrenic abscess in December, 1953 In May, 1951, she weighed 8 st 13 lb In March, 1954, six months after the total gastrectomy she weighed 8 st but was eating well and her bowels were regular In March, 1956, she weighed 7 st 7 lb but was well, with regular bowel actions and a good appetite She has remained well since with no further loss of weight

Summary —This woman had a total gastrectomy with Roux-en-Y reconstruction for recurrent anastomotic ulceration Four years later she was well but had lost 20 lb in weight in three years Her weight has not changed since Her hæmoglobin is 90%, and she is doing her housework

Case 3 —A man, aged 31, had a Polya-type partial gastrectomy in 1941 for duodenal ulcer of five years' standing Ulcer symptoms returned in 1943, and he had periods of medical treatment in 1943, 1944, and 1949 In September, 1952, a further Polya type gastrectomy was done for anastomotic ulceration Three months later ulcer symptoms returned once more with some loss of weight, and in September, 1953, a total gastrectomy, with an end to side œsophago-jejunostomy and a side-to-side entero-enterostomy between afferent and efferent loops (fig 3), was done for a large anastomotic ulcer The patient made an uneventful recovery In November, 1952, after the second partial gastrectomy, he weighed 10 st 5 lb and in September, 1953, 10 st 3 lb In January, 1954, four months after the total gastrectomy he weighed 9 st 5 lb and had a fair appetite but was troubled by heartburn, bilious vomiting, and dysphagia A barium meal, however, showed a normally functioning anastomosis His symptoms remained unchanged, but he continued to lose weight until March, 1956, when he weighed 8 st 10lb Revision of the anastomosis was considered at this time, but it was thought that the symptoms did not warrant the risks involved When last seen in August, 1957, four years after the total gastrectomy,

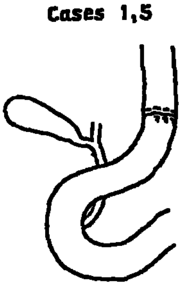

Fig 1—End-to-end œsophago-duodenal anastomosis

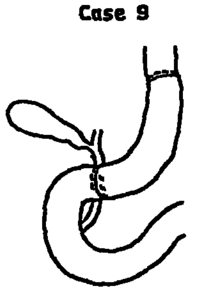

Fig 2—Jejunal-loop replacement with œsophago - jejunal and jejuno-duodenal anastomoses

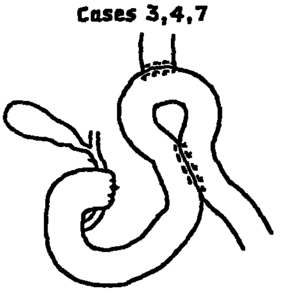

Fig 3—End-to-side œsophago-jejunal anastomosis with side-to-side jejuno-jejunostomy

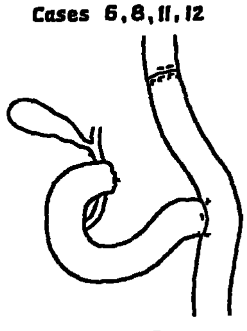

Fig 4—Roux-en-Y reconstruction with end-to-end œsophago-jejunal anastomosis

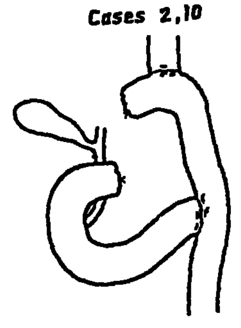

Fig 5—Roux-en-Y reconstruction with end to-side œsophago-jejunal anastomosis

the patient still had heartburn, bilious vomiting, and a poor appetite, but his weight was steady at 8 st 10 lb His hæmoglobin was 89% He is at work

Summary.—This man had recurrent anastomotic ulceration following a Polya-type partial gastrectomy for duodenal ulcer, it recurred after a further gastrectomy Total gastrectomy, with an end-to-side œsophago-jejunal anastomosis and a side-to-side entero-enterostomy between afferent and efferent loops, was done four years ago He has lost 23 lb and is troubled by heartburn, bilious vomiting, and a poor appetite but he is able to work.

Case 4.—A man, aged 52, presented in December, 1953, with eighteen months' history of loss of weight (3 st.), epigastric discomfort, and anorexia A barium meal showed deformity of the pyloric antrum suggesting carcinoma At operation the antrum was found to be indurated and the subpyloric glands enlarged and hard A total gastrectomy, with end-to-side œsophago-jejunostomy and side-to-side entero-enterostomy between afferent and efferent loops (fig 3), was done The patient made an uneventful recovery Histological examination of the resected stomach and glands revealed no evidence of malignancy In October, 1953, two months before the operation, he weighed 12 st. 9 lb By March, 1954, six months later, his weight had decreased to 11 st. 12 lb , his appetite was poor, and he complained of bilious regurgitation and dysphagia A barium meal, however, showed no hold-up By August, 1954, there was some improvement in appetite and energy, but the bilious regurgitation persisted, and he had lost another 3 lb in weight He was last seen in June, 1955, eighteen months after the total gastrectomy, when his condition was unchanged His hæmoglobin was 92% He could not be traced in November, 1956, having moved from London

Summary—This patient had a total gastrectomy, with an end-to-side œsophago-jejunal anastomosis and side-to-side entero-enterostomy between afferent and efferent loops, on the mistaken radiological and operative diagnosis of carcinoma of the pyloric antrum After this he lost 14 lb in weight and has had troublesome bilious vomiting

Case 5—A married woman, aged 71, was admitted in December, 1953, with severe ulcer dyspepsia and melæna She had had previous bouts of ulcer dyspepsia in 1913, 1943, 1951, and 1952 Gastroscopy showed an hour-glass deformity of the stomach and three gastric ulcers A barium meal was reported as showing a single ulcer At operation the appearances were those of a gastric carcinoma, and a total gastrectomy with an end-to-end œsophago-duodenostomy (fig 1) was done The postoperative course was uneventful Histologically the gastric ulcer was benign, but a leiomyoma was also found near by Before the operation the patient weighed 7 st 6 lb , three months later, in March, 1954, she weighed 7 st 3 lb , could eat normal meals, and was feeling well, and her bowels were regular She had palpitations and faintness sometimes, mainly after sweet foods Since then she has improved steadily, with increasing appetite, energy, and weight, and fewer dumping symptoms When last seen in May, 1957, she weighed 7 st 13 lb , could eat anything, and had regular actions of her bowels Her hæmoglobin was 84%

Summary—This old lady had a total gastrectomy with an end-to-end œsophago-duodenostomy because of the operative diagnosis of gastric carcinoma, which was proved to be erroneous She has gained 10 lb in weight since the operation and is in excellent health three and a half years later

Case 6.—A man, aged 47, underwent partial gastrectomy for a duodenal ulcer of ten years' standing Ulcer pain recurred a year later, and he lost a great deal of weight in the next three years In January, 1954, a barium meal showed a large anastomotic ulcer, so a total gastrectomy with a Roux-en-Y œsophago-jejunal reconstruction (fig 4) was done His postoperative course was marred by a wound infection, but he made a good recovery Before the original partial gastrectomy he weighed 10 st., but by October, 1953, his weight had decreased to 9 st 5 lb After the total gastrectomy he lost weight despite a good appetite and regular bowel actions He reached his lowest weight—8 st 12 lb —in July, 1954, but since then he has gained weight and when last seen in April, 1957, he weighed 9 st 3 lb He was then well, with a good appetite and energy, occasional bulky stools, and a mild iron-deficiency anæmia (Hb 80%)

Summary—This man, aged 51, had a total gastrectomy with a Roux-en-Y reconstruction in January, 1954, for anastomotic ulcer Three years later he is well, with a good appetite and energy His weight is almost the same as before total gastrectomy

Case 7—A boy, aged 15, had duodenal-ulcer dyspepsia in 1940 He had a perforation and hæmatemesis in 1942, while in the Merchant Navy, a partial gastrectomy was done in 1948, a further gastrectomy, with a vagotomy, was done in 1950 for anastomatic ulcer He was treated medically in 1952 for another anastomotic ulcer, and in 1953 a gastrocolic fistula was repaired A further vagotomy was attempted in 1954, but later that year a further gastric resection was necessary Within a few months the patient had his sixth anastomotic ulcer, and a total gastrectomy, with end-to-side œsophago-jejunostomy and side-to-side entero-enterostomy between the afferent and efferent loops (fig 3), was done in February, 1955 Convalescence was complicated by an empyema, which resolved with conservative treatment. In 1950, at the time of his third gastrectomy, he weighed 7 st 5 lb After the repair of the gastrocolic fistula his weight fell to 6 st 9 lb At this time he had very severe steatorrhœa, which persisted after the total gastrectomy, his weight two months later being only 6 st Since then, however, his condition has improved slowly, and when last seen in January, 1957, two years after the total gastrectomy, he was regaining some appetite and his weight had increased to 8 st 2 lb He is still troubled by steatorrhœa, but this can be controlled partially by aureomycin

Summary—This young man had his first partial gastrectomy at the age of 23 After further resections and vagotomy had failed to prevent the recurrence of ulcers, the sixth recurrence was treated by total gastrectomy, the œsophagus being anastomosed to the side of a jejunal loop, with entero-enterostomy between afferent and efferent loops Severe steatorrhœa persisted after this operation, but the patient has managed to gain weight.

Case 8.—A man, aged 38, had melæna in 1917 He was operated on in 1924 at another hospital and again in 1929 for further hæmorrhages He had twelve further attacks of melæna up to 1943, when, after yet another severe melæna, a Polya-type partial gastrectomy was done for duodenal ulcer In the next twelve years the patient had sixteen more episodes of gastrointestinal hæmorrhage He had never had ulcer pain He had always bled profusely from cuts, but a full investigation of his blood by Dr J V. Dacie revealed no abnormality By the time he was referred to the Central Middlesex Hospital in March, 1955, he had had 200 bottles of blood by transfusion At this time a total gastrectomy with a Roux-en-Y reconstruction (fig 4) was done for a large anastomotic ulcer He made a good recovery In November, 1956, eighteen months after the total gastrectomy, his general practitioner reported " I think he could eat a larger meal than I " He was gaining weight and at work. In November, 1957, he wrote " I feel very fit and in the best of health My weight is nearly 12 st With regard to food, I can eat anything, usually four good meals a day "

Summary—This patient had recurrent gastrointestinal hæmorrhages between 1917 and 1955 and received 200 pints of blood by transfusion The hæmorrhages continued despite three gastric operations, the last a Polya-type partial gastrectomy A total gastrectomy with a Roux-en-Y reconstruction was done in March, 1955, and in November, 1957, the patient is in excellent health

Case 9.—A man, aged 32, was seen in 1946 with four years' history of ulcer dyspepsia A barium meal confirmed the diagnosis of duodenal ulceration The ulcer perforated in 1950 and was treated by suture In August, 1951, a Polya-type partial gastrectomy was done, but, because of continuing loss of weight, was refashioned to a jejunal-loop replacement gastrectomy in January, 1952 In February, 1953, streptococcal liver abscess developed and required surgical drainage In March, 1954, ulcer pain returned, and an anastomotic ulcer was found in the jejunal segment. This was resected and a Billroth-I anastomosis made While the patient was still in hospital another anastomotic ulcer developed, and a vagotomy was done but failed to cure the ulcer, which persisted despite medical treatment In April, 1955, a total gastrectomy, with a jejunal segment replacement (œsophago-jejuno-duodenal anastomosis) was done (fig 2) Postoperative convalescence was uneventful Before the first partial gastrectomy this patient weighed 9 st 6 lb , and just before the total gastrectomy, despite his stormy career, 9 st 2 lb Six months later his weight was 8 st 8 lb and it has remained unchanged since When last seen in August, 1957, he was still complaining of epigastric fullness after meals and some pain and nausea He has mild steatorrhœa, but his hæmoglobin is 92%

Summary—This man had an unsuccessful Polya partial gastrectomy in August, 1951 Conversion to a jejunal-loop replacement gastrectomy was followed by recurrent anastomotic ulceration, which was not cured by conversion to a Billroth-I

SUMMARY OF DATA OF 12 PATIENTS TREATED BY TOTAL GASTRECTOMY FOR BENIGN PEPTIC ULCER

Case no	Sex	Age at T G (yr)	Reason for T G	Type of reconstruction	Weight before T G (lb)	Weight at F U (lb)	Length of F U (ms)	Results
2	F	54	A U	Roux-en-Y	125	105	50	Good
6	M	51	A U	Roux-en-Y	129	128	39	Very good
8	M	56	A U	Roux-en-Y	Not known	Increasing	32	Very good
10	F	34	A U	Roux-en-Y	87	98	31	Fair (pain in thoracotomy scar)
11	M	54	A U	Roux-en-Y	Not known	Not known	21	Very good
12	M	49	A U	Roux-en-Y	150	149	20	Very good
1	M	48	G U	Œsophago-duodenal anastomosis	125	87	74	Poor (pulm tuberculosis)
5	F	71	G U	Œsophago-duodenal anastomosis	104	111	41	Very good
3	M	45	A U	Loop reconstruction with lateral entero-anastomosis	143	122	48	Poor
4	M	52	G U	Loop reconstruction with lateral entero-anastomosis	177	162	18	Fair
7	M	31	A U	Loop reconstruction with lateral entero-anastomosis	93	114	24	Fair (steatorrhœa)
9	M	47	A U	Jejunal replacement œsophago-jejuno-duodenal anastomosis	128	120	28	Fair

A U, anastomotic ulcer F U, follow-up G U, gastric ulcer T G, total gastrectomy

reconstruction or by vagotomy In April, 1955, total gastrectomy with a jejunal-loop replacement was done The result has been only moderately good

Case 10 —A married woman, aged 23, began to have ulcer symptoms in 1944 and shortly afterwards a duodenal ulcer perforated and was sutured By May, 1950, pyloric stenosis had developed, and a gastroenterostomy was done Eighteen months later ulcer symptoms recurred, and an anastomotic ulcer was found in August, 1953, and was treated by a Polya-type partial gastrectomy Ulcer pain recurred again within three months, but no anastomotic ulcer was found The patient was referred to the Central Middlesex Hospital in April, 1955, and a barium meal now showed an anastomotic ulcer Total gastrectomy with a Roux-en-Y reconstruction (fig 5) was done Postoperative convalescence was uneventful We have no record of her earlier weight, but two months after the total gastrectomy she weighed 6 st 4 lb She then complained of retrosternal discomfort after meals but was otherwise well In January, 1956, nine months after her operation, she was readmitted with retrosternal pain radiating to her shoulders Physical examination, barium meal, and œsophagoscopy were unrevealing In December, 1956, she weighed 6 st 8 lb, still had some pain, and had iron-deficiency anæmia (Hb 72%) In November, 1957, her general practitioner reported that she now weighed 7 st, her appetite was fair, and her hæmoglobin was 90% He wrote "Having had so much trouble in the past, she finds it difficult to believe she has not another ulcer " She is doing her housework

Summary —This young woman had an unsuccessful gastroenterostomy for a duodenal ulcer with pyloric stenosis in 1950 A Polya-type partial gastrectomy was done in 1953 for anastomotic ulceration This recurred, and in April, 1955, total gastrectomy with a Roux-en-Y gastrectomy was done She still complains of chest pain but has gained weight and has a fair appetite

Case 11 —A man, aged 30, began to have ulcer dyspepsia in 1931 In 1933 he had a gastroenterostomy for duodenal ulcer The ulcer pain returned twelve years later, and in 1945 a further operation was done In 1947 and in 1949 further anastomotic ulcers were excised, and in 1951 a vagotomy was done for yet another ulcer In 1953 a further ulcer caused a hæmatemesis, which was treated medically, and in April, 1955, a large anastomotic ulcer, adherent to the eighth rib anteriorly, was excised In November, 1955, the patient was referred to the Central Middlesex Hospital, where a barium meal showed a large stomal ulcer He was readmitted in January, 1956, and total gastrectomy with a Roux-en-Y reconstruction (fig 4) was done His postoperative course was uneventful In November, 1957, twenty-two months after the total gastrectomy, his general practitioner reported that the patient had given up using pethidine, had an excellent appetite, and was gaining weight The doctor wrote "He is absolutely marvellous compared to the old days I am most impressed with this case as the transformation is astonishing "

Summary —This man had a series of anastomotic ulcers excised and vagotomy done after an initial gastroenterostomy for duodenal ulcer Total gastrectomy in January, 1955, with Roux-en-Y reconstruction has given a very good result, judged twenty months later

Case 12.—A man, aged 27, began to have ulcer dyspepsia in 1934 A perforation of a duodenal ulcer followed in 1939 In 1943 a Polya-type partial gastrectomy was done In 1944, 1947, and 1951 he had perforations of anastomotic ulcers treated by suture He continued to have ulcer pain for the next two years and had melæna in 1952 After this he was well for two years, but in September, 1955, he was admitted with a perforated anastomotic ulcer and had a subtotal Polya-type gastrectomy In December, 1955, he had another anastomotic ulcer He was admitted in February, 1956, and underwent total gastrectomy with a Roux-en-Y reconstruction (fig 4) His postoperative convalescence was uneventful In April, 1955, during a period of relatively good health, he weighed 10 st 10 lb In April, 1956, two months after the total gastrectomy, he complained of heartburn at night but was able to eat a full meal He was troubled by constipation, for which he took 'Senokot' His weight was 10 st 1 lb By June, 1956, he was back at work, and when last seen in November, 1957, twenty months after his total gastrectomy, he was very well, could eat anything, and weighed 10 st 9 lb He said "Why did you not do this operation ten years ago?"

Summary —This man had a series of anastomotic ulcers following a Polya-type partial gastrectomy in 1943 In September, 1955, a subtotal gastrectomy was done for yet another perforated anastomotic ulcer, but two months later anastomotic ulceration had recurred, and in February, 1956, total gastrectomy with a Roux-en-Y reconstruction was done, with very good results

Conclusions

No total gastrectomy for benign ulcer was done at the Central Middlesex Hospital before 1951 Since then 12 patients have had this operation for benign ulcer, and all have survived In 9 patients the operation was done for recurrent anastomotic ulceration, in the remaining 3 patients the lesion was a gastric ulcer, mistaken for carcinoma at operation

The accompanying table summarises the results obtained in these 12 patients There is no doubt that those patients who had the Roux-en-Y reconstruction have had the best results Of these 6 patients (cases 2, 6, 8, and 10–12), all operated on for anastomotic ulcer, 4 are very well, eating normal meals, and leading normal lives twenty to thirty-nine months after the operation 1 other patient is well but has lost 20 lb in weight, but other factors may be partly responsible, and the remaining 1 is well in every way but continues to be troubled by pain in the thoracotomy scar 3 patients (cases 3, 4, and 7) have had loop reconstructions with lateral entero-anastomosis, none of these has been really successful, though they are able to work 1 has severe steatorrhœa, present even before total gastrectomy, but has managed to gain weight with the aid of aureomycin The 2 others have lost weight and are troubled by bilious vomiting and heartburn Direct œsophago-duodenal anastomoses were done for 2 patients (cases 1 and 5), with excellent results in 1 The other patient has no dyspeptic symptoms but has contracted severe pulmonary tuberculosis four years and four months after the operation

The creation of an artificial gastric reservoir from a jejunal loop has not been a success in the 1 case where this was done (case 9) These results agree with the experience with patients undergoing total gastrectomy for carcinoma at the Central Middlesex Hospital Brintnall et al (1956), on the basis of a careful analysis of 58 patients with total gastrectomy mainly for carcinoma, also concluded that the Roux-en-Y reconstruction (24 patients) gave the best results They too were disappointed with the results of direct œsophago-duodenal anastomosis (3 cases), mainly because of loss of weight and bilious regurgitation They found that iron was the only factor required in larger than normal amounts in their patients

All our patients have had regular doses of intramuscular vitamin B_{12}, and no instance of macrocytic anæmia has been found among them Iron-deficiency anæmia, however, is liable to occur, and we agree with Brintnall et al (1956) that these patients need additional oral iron, in the same way as do patients who have undergone partial gastrectomy

From our experience with these 12 patients we feel that total gastrectomy, if done with a Roux-en-Y reconstruction, is a justifiable operation for patients with anastomotic ulceration not cured by an adequate partial gastrectomy and vagotomy, and even in patients with simple gastric ulcer in whom, at operation, the findings strongly suggest malignancy and in whom subtotal resection would not have given sufficient clearance Adequate maintenance doses of vitamin B_{12} and oral iron are essential for the well-being of these patients In our experience the nutrition of patients with Roux-en-Y reconstructions is entirely satisfactory They can eat a normal amount of food and can maintain their weight

Summary

The case histories of 12 patients who have had total gastrectomy for benign peptic ulcer are presented

The Roux-en-Y reconstruction gives satisfactory results and is to be preferred to other methods of reconstruction The operation is justified in patients with obstinate anastomotic ulceration not arrested by adequate gastrectomy and vagotomy

The nutrition of patients with the Roux-en-Y reconstruction is satisfactory They must, however, be given regular maintenance doses of vitamin B_{12} and oral iron

These patients were all admitted to the Gastroenterological Unit of the Central Middlesex Hospital under the care of Dr F Avery Jones, to whom we are indebted We also wish to thank our colleagues, Mr T G I James, Mr F A Henley, and Mr H Hasheman

URICOSURIC EFFECT OF DICOUMAROL

Ole Evald Hansen
M B Copenhagen
CLINICAL ASSISTANT, MARSELISBORG HOSPITAL, ÅRHUS, DENMARK

Cai Holten
M D Copenhagen
PROFESSOR OF MEDICINE, UNIVERSITY OF ÅRHUS

SINCE dicoumarol was introduced about fifteen years ago into therapy by Butt et al (1941) and Lehmann (1942) it has been increasingly used prophylactically and therapeutically in conditions connected with thrombo-embolism The attention of pharmacologists and clinicians has been focused on its effect on clotting of the blood by hampering the formation of proconvertin and prothrombin in the liver Some workers look on this as its sole pharmacological action (Møller 1955, Goodman and Gilman 1955), but this standpoint is no longer tenable

TABLE I—SERUM URIC-ACID LEVELS (MG PER 100 ML) IN SERUM BEFORE AND AFTER DICOUMAROL IN HEALTHY PERSONS

—	Person no				
	1	2	3	4	5
Before	5 3	4 9	5 4	4 1	6 1
After	3 7	4·4	4 4	3 4	5 0
% fall	30	10	19	17	18

Sougin-Mibashan and Horwitz (1955) investigated the effect of 'Tromexan' (ethylbiscoumacetate) on the metabolism of uric acid in the rat, the dalmatian dog, and man, using Brown's colorimetric method for determining the uric acid (Kolmer and Boerner 1945) After a single dose of tromexan 1 2–1 8 g by mouth they found a pronounced fall in the level of uric acid in the serum and a significant rise in the ratio of uric-acid clearance to creatinine clearance

We have investigated whether dicoumarol produces similar effects We estimated the uric acid in both serum and urine by enzymatic spectrophotometry by the method of Prætorius (1949) modified by Prætorius and Poulsen (1953) All the determinations were made as double determinations, the deviations from the average rarely exceeding ±3%

Material and Method

The levels of uric acid in the serum were determined in 40 patients before and during anticoagulant treatment 27 patients had myocardial infarction, in 9 patients this disease was suspected, 3 had pulmonary embolism, and 1 had undergone a bypass operation on a femoral artery

The anticoagulant treatment was given according to principles described by Holten (1955) Initially a dose of 500–750 mg of dicoumarol was given, after which dicoumarol was withheld for two or three days The next dose depended on the effect of the initial dose on the prothrombin time, and the daily maintenance dosage was adapted according to daily determinations of the prothrombin time During the first two days after the start of treatment intramuscular long-acting heparin 15,000–20,000 I U was injected at intervals of eight hours

To determine the effect of dicoumarol on the uric-acid level in the serum under comparable conditions we chose as standard the first fasting sample taken and related this to the lowest level of uric acid in the serum after the initial dose of dicoumarol

Results

In the vast majority of cases the level falls During treatment with the maintenance dosage of dicoumarol the uric-acid level in the serum rises again to a fairly constant value, which in almost all cases is lower than that of the first fasting sample

The average fall was 1 8±0 2 mg per 100 ml In 31 patients—i e, more than 75%—the level of uric acid in the serum fell more than 20%, in 4 patients it fell 10–20%, and in 5 patients no significant change was observed The possibility that this fall might be due to the myocardial infarction or to the heparin was investigated by determining the level of uric acid in the serum before and after a dose of 500–700 mg of dicoumarol in 5 healthy persons (table I)

The uric-acid levels in the serum were determined at least thrice during the first twenty-four hours after the administration of dicoumarol and subsequently daily for three to seven days In table I the lowest levels after dicoumarol are given, these were usually found twenty-four hours after the administration of dicoumarol

TABLE II—SERUM LEVELS, EXCRETION, AND CLEARANCE OF URIC ACID AND CLEARANCE OF CREATININE

Person no	Day no	Uric acid in serum (mg per 100 ml)	Urinary excretion of uric acid (mg per 24 hr)	Clearance (ml. per min.)	
				Uric acid	Creatinine
4	1	4 1	714	11 4	161
	2	4 0	777	11 7	107
	3	4 1	944	15 2	132*
	4	3 8	860	15 4	126
	5	3·4	691		118
	% difference	−17	+27	+31	
5	1	6 1			100
	2	5 7	426	4 9	70
	3	5 2	482	5 8	70
	4	4 9	445	4 6	65
	5	5 7	625	7 4	67*
	6	5 0	621	7 0	104
	7	5 2	517		
	% difference	−18	+39	+45	

* Dicoumarol 500 mg was given after fasting blood-samples had been *drawn at the beginning of days 3 and 5*

In 2 of the healthy persons (nos 4 and 5) the urinary excretion of uric acid in twenty-four hours was determined for several days, simultaneously the clearance of endogenous creatinine was determined The results are given in table II

Discussion

These results show that dicoumarol increases the urinary excretion of uric acid and decreases the level of uric acid in the serum It is generally believed that uric acid is freely filtered in the glomeruli, and that about 90% of the uric acid filtered is reabsorbed in the tubules Since the clearance of creatinine is not changed while that of uric acid increases after the administration of dicoumarol, dicoumarol probably decreases the tubular reabsorption of uric acid

The well-known uricosuric drugs have similar actions This has been shown for probenecid by Gutman and Yu (1951), for salicylic acid by Crone and Lassen (1955) and for tromexan by Sougin-Mibashan and Horwitz (1955)

This uricosuric effect of the coumarin derivatives is of interest in connection with the significance of the level of uric acid in the serum in the pathogenesis of atherosclerosis Huchard (1899) compared the changes in the arteries in uric arthritis with the changes in the heart in rheumatic fever, and Roberts (1900) mentioned the significance of "uric-acid diathesis" for the development of thromboembolic processes Gertler and White (1954) mention the possible significance of uric acid in the serum as a harmful agent causing deposition of cholesterol The question arises do the coumarin derivatives improve the prognosis of myocardial infarction solely by their anticoagulant effect, or is their uricosuric effect also important? At any rate it is well established that the effect on clotting is not the only effect of the coumarin derivatives

Summary

In 40 patients with myocardial infarction and other thromboembolic conditions dicoumarol in initial doses of 500–750 mg caused an average decrease of 1 8±0 2 mg per 100 ml in the level of uric acid in the serum On maintenance doses of dicoumarol this level rose a little but not to its pre-treatment value

In experiments on healthy volunteers dicoumarol caused a significant fall in the level of uric acid in the serum and increased urinary excretion of uric acid, probably because dicoumarol hampers tubular reabsorption

FRACTURES OF THE PARIETAL BONE IN CHILDREN

Maurice Ellis
M A, M B Cantab, F R C S, D T M & H
SURGEON-IN-CHARGE, CASUALTY DEPARTMENT,
GENERAL INFIRMARY, LEEDS

There is a type of fracture of the parietal bone in children with distinctive clinical features In 1955-57 twelve such cases were seen in the casualty department of the General Infirmary at Leeds, in which 38,000 new cases annually are treated

Clinical Picture

An anxious parent brings to the casualty department a small child with a lump on the side of its head and a history of a fall on to its head some days previously After the initial upset the child went on eating, sleeping, and playing as before The parent found nothing wrong with the head shortly after the fall but discovered some days later (in this series 1–14 days) a lump on the side of the head In the casualty department the child is found to be perfectly healthy with no physical signs except the lump

The lump has special characteristics In some children rather long hair over it makes it difficult to see without careful scrutiny Palpation, however, reveals a soft cystic swelling on one side of the head and of appreciable size—usually 3 or 4 inches in diameter It is roughly circular and not bounded by any of the suture lines of the skull Its edge is fairly easy to define but not clearcut There is no bruising in the overlying skin or superficial fascia The swelling is uniformly soft and bears no resemblance to the ordinary hæmatoma of the scalp, with its soft centre and firm edge

Diagnosis

A fracture of the underlying parietal bone can be confidently diagnosed on the physical characteristics of the swelling alone In ten of these cases immediate radiography revealed a linear fracture of the parietal bone, sometimes running into the neighbouring bones The size of the fracture bore no relation to the size of the swelling In one case, however, radiography two days after the injury, and again three days after, showed no fracture, but fourteen days later revealed the fracture line very clearly These eleven patients were aged from 6 months to 3 years The twelfth case was in a boy, aged 9 years, in whom radiography at his first attendance and twice subsequently, revealed no fracture, but nevertheless the clinical features and characteristics of the swelling were typical

Course

The courses of these cases were very similar The child remained perfectly well The swelling remained

unchanged in size for some days and then relatively abruptly began to disappear it shrank in size, diameter, and depth, but its consistence remained unchanged In a few days the swelling completely disappeared, leaving no trace In the eleven cases in which a fracture was demonstrated radiographically the swelling disappeared 12–21 days after it had appeared In the boy aged 9 years the swelling took 32 days to disappear In eleven of these twelve patients there were no further symptoms The twelfth patient, a boy aged 18 months, returned four months later with a history of four days' swelling in the same site, of apparently spontaneous origin Radiography showed the fracture line to be still present The subsequent course of this swelling was the same as that of the other swellings it disappeared in three weeks and has not recurred

Discussion

A search of standard surgical textbooks and special textbooks on head injuries revealed no reference to this swelling in association with a fractured parietal bone A search of the medical literature was equally without result Several articles have been published by radiologists describing fractures of the skull in children Ireland (1932) states that fracture of the parietal bone is the commonest fracture of the skull in children He points out that the fracture line in the parietal bone often runs into the neighbouring bones (as in many of the present cases) He makes no reference to any associated swelling overlying the fracture Pia (1953), who reviewed the literature on fractures of the skull in children and described a large number of personal cases, made no reference to the associated swelling in fractures of the parietal bone

The nature and site of this swelling are of considerable interest Because the swelling shows no overlying bruising and is not delimited by the suture lines of the skull, it is postulated that the swelling lies between the galea aponeurotica and the periosteum of the skull Investigation of the nature of the fluid, however, is hindered by consideration for the patient When experience has shown that the swelling is absorbed spontaneously, it is unjustifiable to subject a small child to elaborate investigations In the baby girl, aged 15 months, whose swelling and radiograph are shown in figs 1 and 2, the swelling was so large that aspiration was considered justified

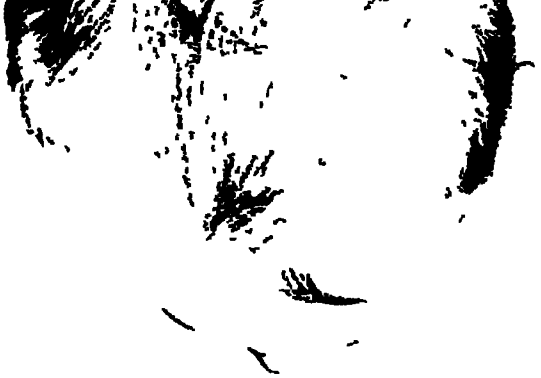

Fig 1—Swelling over parietal bone in baby aged 15 months

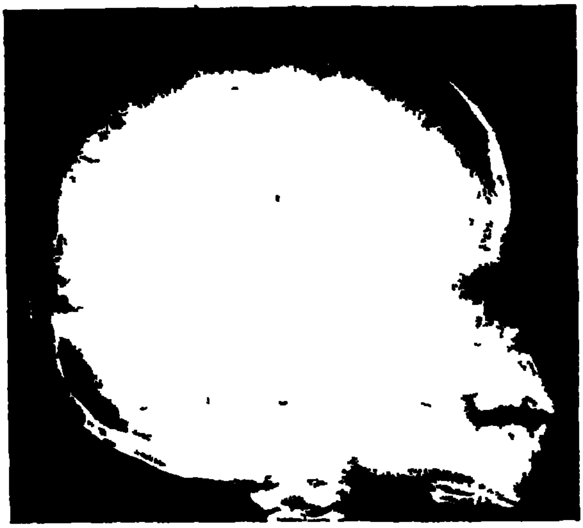

Fig 2—Radiograph of same case as in fig 1

Aspiration through the shaved scalp produced 50 ml of fluid which was heavily contaminated with blood and resembled that obtained by lumbar puncture after subarachnoid hæmorrhage On standing the blood settled in the container, leaving a red-stained thin fluid above it, which was taken to be cerebrospinal fluid (C S F) with some hæmolysis The sugar content of this fluid was consistent with its being C S F

Three days after aspiration a swelling had reappeared about half the original size but of exactly similar consistence Re-aspiration was not considered justifiable This new swelling was completely absorbed in two weeks

It is postulated that with the fracture of the parietal bone there was a subjacent tear of the meninges Leaking C S F mixed with blood oozed through the fracture into the loose tissue spaces below the galea In case 12, in which there was no fracture, fluid is assumed to have oozed between the suture lines Lumbar puncture would probably yield bloodstained fluid and support this theory It will be appreciated, however, that there was great reluctance to submit these children to such an unpleasant investigation, which was really only of academic interest

It seems fairly clear that, in these cases, there is no danger of intracranial compression, and all these patients were treated as outpatients

Summary

Twelve small children in whom a soft swelling developed over a parietal bone some days after an injury are reported In eleven cases there was a subjacent fracture of the parietal bone, and the swelling was spontaneously absorbed within three weeks

This type of swelling associated with fracture is apparently hitherto undescribed

It is postulated that this swelling is due to a leak of C S F and blood from a subjacent tear of the meninges, through the fracture line into the space below the galea aponeurotica

Preliminary Communication

THE MEMBRANE OXYGENATOR

SOME ASPECTS OF OXYGEN AND CARBON DIOXIDE TRANSPORT ACROSS POLYETHYLENE FILM *

CARDIAC surgery has entered a new phase in its development Operations within the chambers of the heart are commonplace, and most are possible because machines take the place of cardiopulmonary function during such surgery In the design of these machines the most vexed question remains the choice of method for gas exchange There is a general leaning towards the principle of imitation of the normal pulmonary anatomy, where the blood is separated from the gas by a membrane Pursuit of this ideal is exemplified by the continuing work of Clowes [1] and Kolff [2]

During experiments with a design made by one of us (M L B) of an oxygenator provided with a membrane certain factors have emerged which may alter the direction of emphasis in the search for the ideal membrane, and we have felt it of sufficient interest to report some of these initial experiments They underline the importance of the character of such membranes in regard to the transport of carbon dioxide and indicate that this property may be of greater significance than has hitherto been realised

METHOD

The membrane chosen for these studies was polyethylene $^1/_{1000}$ inch thick It was supplied by the Visking Corporation, of Centerville, California The mechanical description of the lung will be published elsewhere

The design tested provided a surface area of 9 5 sq m for gas exchange and allowed a blood-flow of 3 litres a minute Ancillary reservoirs, tubing, and a roller pump of DeBakey type, together with the oxygenator, contained 3 litres of blood and hence allowed a recirculation time of one minute for the blood contained

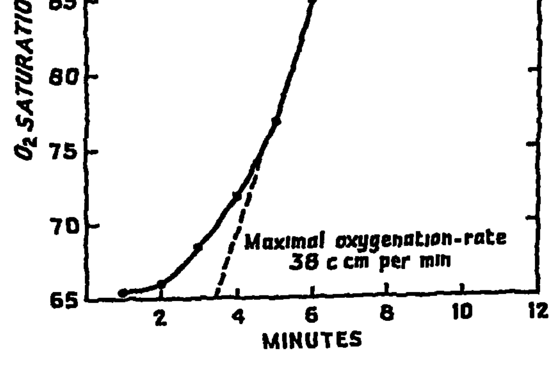

Fig 1—Change in oxygen saturation of blood on admission of oxygen into membrane lung

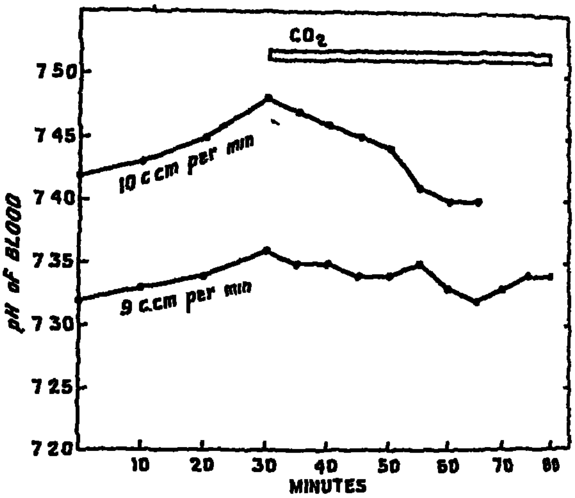

Fig 2—Change in pH before and after carbon dioxide is added to blood at 9 c cm a minute and at 10 c cm a minute

The flow of gas through the apparatus was more than 60 litres a minute to avoid stagnation The respiring gas was recirculated through a carbon-dioxide absorber and through a gas heater, which could maintain a constant temperature after the apparatus had been preheated to the required degree

For all the experiments beef blood was drawn from the slaughterhouse on the day of the study It was introduced after the apparatus had been thoroughly rinsed with warm saline solution and after the gas spaces had been completely filled with nitrous oxide This latter precaution allowed recirculation of blood within the apparatus without appreciable alteration in the oxygen saturation and thus ensured proper filling and mixing After repeated measurements for oxygen content had established a steady state, the nitrous oxide was vented, and its place was taken by oxygen admitted at a rate of more than 30 litres a minute Thereafter samples were withdrawn at one minute intervals until again a steady state was reached The measurements of oxygen content were made by cuvette oximeter †

During this period the blood pH was measured at five-minute intervals ‡ Such measurements were continued throughout the study

After the rate of oxygen transport across the membrane had been determined, the ability to excrete carbon dioxide was estimated This gas was added directly to the blood as it entered the oxygenator Injections were made at a rate which was either at or in excess of the expected rate of excretion calculated from the permeability coefficient and the partial pressure of carbon dioxide [3]

To eliminate inefficient absorption of carbon dioxide in the ventilating system a sample of the circulating gas was drawn continuously through a Liston-Becker CO_2 analyser,§ and at no time during the study was the presence of measurable amounts of carbon dioxide detected

RESULTS

The results indicate that the average diffusion-rate of oxygen into the blood was 38 c cm a minute in the described circumstances (fig 1)

Only an average of 9 c cm of carbon dioxide a minute could be added to the blood in these circumstances without causing a considerable change in the pH An increase to 10 c cm a minute depressed the pH uniformly (fig 2)

n the absence of appreciable metabolism of the blood uring the test it was inferred that the depression of the H represented a failure of the membrane to excrete the dded carbon dioxide at the rate of its addition

DISCUSSION

Plastic membranes have clearly defined characteristics in respect to the passage of gases across them, and it has become established practice to use such membranes for the continuous separation of gaseous mixtures by fractional diffusion Those in use in blood oxygenators at present are no exception to these laws

The ratio of permeability values for oxygen and carbon dioxide when polyethylene is the membrane is

$$\frac{\text{Permeability coefficient of } CO_2}{\text{Permeability coefficient of } O_2}=4$$

Hence four times as much carbon dioxide as oxygen may be expected to pass through a given membrane at the same partial pressure To achieve worthwhile efficiency in present oxygenator designs it is usual to maintain an environment of 100% oxygen outside the membrane and thus a partial pressure of about 750 mm Hg, but to maintain an acceptable blood pH the partial pressure of carbon dioxide in the blood cannot rise much above 50 mm Hg In fact, a partial pressure ratio of 15 to 1 could exist in favour of oxygen diffusion

In these circumstances the relatively greater diffusion-rate (four times) of carbon dioxide is insufficient to counteract the partial pressure ratio, and therefore carbon dioxide can only be transported at about a quarter of the rate obtaining for oxygen Similar characteristics must apply to all membranes whose function depends solely on gaseous diffusion, and, only if the permeability ratio for CO_2/O_2 were about 15, could a respiratory quotient of 1 be maintained in the presence of pure oxygen

The results obtained in the present study (that 38 c cm of oxygen but only 9 c cm of carbon dioxide could be exchanged across the polyethylene membrane) support these theoretical considerations and closely parallel the expected values We are thus forced to accept certain principles in the design of a membrane oxygenator Where *gaseous diffusion is the only mechanism of gas exchange* the rate of diffusion of carbon dioxide is the "bottleneck" determining the area of membrane required In the case of the polyethylene film studied this requirement necessitates a surface area four times as large as would be required for oxygenation with pure oxygen, which would involve the construction of an apparatus providing more than 250 sq m of surface area if adult man is to be adequately respired—for practical reasons an impossibility

Fortunately, much more efficient alternatives to polyethylene exist, but it seems unlikely from the known characteristics of such membranes that they will allow of a carbon-dioxide/oxygen diffusion ratio greater than 5 to 1 This infers that, if oxygenation demands cannot adequately be met when room air is the respiring gas, some other type of membrane will have to be found

Hitherto the search for effective membranes has been confined to those whose surface is "non-wetting" Such surfaces are inherently kind to blood and are desirable from this standpoint, but they do not allow use being made of an important physical property of carbon dioxide This is its solubility in water 25 times as great as that of oxygen It is this property which is used in the animal lung, and it may reasonably be inferred that the principal mechanism of transfer of carbon dioxide across a water-absorbent membrane is its passage as dissolved carbon dioxide

It may therefore be desirable to include the characteristics of "wetting" in the specifications of an ideal membrane Perhaps it may even be advantageous to use two types of membrane in such an oxygenator to obtain the greatest efficiency for both oxygen and carbon-dioxide transport

ASSOCIATION OF CLINICAL PATHOLOGISTS

THE Association's 60th general meeting was held at Trinity College, Dublin, on April 18 and 19 We publish below brief accounts of some of the papers presented at the meeting

Myasthenia Gravis

Dr A. L WOOLF and his colleagues had reported [1] for the first time striking changes in the intramuscular nerve-endings in a case of myasthenia gravis, and similar changes had now been found in two out of a further three cases The changes consisted of sprouting of the distal extremity of the subterminal nerve-fibres (which were sometimes irregularly swollen) and formation of multiple, bizarre, or unduly complex endplates Cholinesterase preparations showed minute deposits of cholinesterase over a wide zone around the endplates, indicating that there were far more sprouts than were detectable with the light microscope alone The changes resembled those seen in myositis, dystrophia myotonica, and thyrotoxic myopathy These diseases had little in common as regards contractility of muscle but all showed evidence of endocrine imbalance Dr Woolf thought the changes in the nerve-endings were the result of muscle-fibre degeneration and lymphorrhages caused by this imbalance, which was also responsible for the disordered contractility

Thyroid Gland after Treatment of Thyrotoxicosis

Dr. R C CURRAN, Dr H ECKERT, and Prof G M WILSON reported that, by searching a hospital's pathological records over many years, 7 cases were found in which the portion of thyroid gland left after partial thyroidectomy was available for histological examination the interval between the surgical operation and the necropsy or biopsy ranged from 1 to 14½ years For comparison, 13 glands treated by therapeutic doses of radioactive iodine had been obtained these 13 patients died in hospital at intervals of a few days to 5½ years after treatment Full necropsies were performed. After partial thyroidectomy, the portion of gland left showed progressively decreasing cellular hyperplasia and increasing colloid storage In the first weeks after treatment with ^{131}I, the irradiated glands showed disruption of follicles, necrosis and damage to epithelial cells, œdema and early fibrosis of the stroma, and widespread vascular lesions, including thrombosis The more chronic effects of radiation treatment included stromal fibrosis and increasing numbers of altered epithelial cells, but more striking were the microfollicular structure and the comparative lack of colloid

The two series of glands also seemed to differ metabolically, as judged by the results of giving a tracer dose of ^{131}I to patients rendered euthyroid by one or other method of treatment In the post-thyroidectomy cases, the level of protein-bound radio-iodine 48 hours after the test dose was almost invariably normal—that is, less than 0 4%—which suggested a normal iodine pool in the thyroid gland In contrast, in the irradiated series, the protein-bound radioiodine remained high on average, suggesting a reduced iodine pool in the thyroid gland, a result apparently in harmony with the histological finding of colloid lack

Histology of Chronic Bronchitis

Dr W K Taylor described the microscopical appearances of biopsy material taken from the carina in 54 cases of chronic bronchitis All cases showed an increase of goblet cells up to 100% of the epithelial cells Transitional-cell metaplasia was a very common finding (60%) and about 12% showed squamous metaplasia Carcinoma-in-situ was seen in a few cases In more than half the sections there was some degree of thickening of the basement membrane In the lamina propria there was often some œdema and, occasionally, dilated lymphatics Plasma cells were not infrequent but polymorphs were rare and no eosinophils were seen Elastic fibres were reduced in number and often absent Fibrosis was uncommon and when present it was fine and diffuse

Bronchiolitis from Nitrous Fumes

Dr A J N Warrack said that nitrous fumes were common in industry (dipping of metals, manufacture of toluene and cellulose, descaling and pickling of steel sheets after firing and rolling) Symptoms varied with concentration of the gas and duration of exposure low concentrations merely provoked mild irritation of the eyes and upper respiratory tract, strong concentrations could cause severe pulmonary œdema Sometimes, however, there was a latent interval of many hours or even days, and symptoms then took the form of dyspnœa, cyanosis, and paroxysmal cough Secondary infection was a danger A man carrying nitric acid in a rubber bucket noticed a leak and held the bucket over another of galvanised iron He was enveloped in thick brown fumes for 30 seconds He felt all right and finished his work Seven days after exposure he sought medical attention, and he was admitted semicomatose and cyanosed to hospital two weeks after the original incident He later died Postmortem examination showed both bronchial trees filled with thick mucopus The lungs were solid and section showed tiny yellow areas with the appearance of purulent bronchiolitis Microscopical examination showed varying degrees of obliterative bronchiolitis from simple epithelial desquamation to complete bronchiolar destruction with surrounding alveolar organisation There was presumably secondary infection of these areas, and it was thus important that antibiotic therapy should be given

Phenol Reaction for Blood-sugar Estimation

Dr T M Healy, reporting on the use of this test for the past two years, said that simple sugars when treated with phenol and concentrated sulphuric acid gave an orange yellow colour, stable for some hours The method gave accurate and consistent results Compared with Folin and Wu's method the results were of comparable accuracy but the phenol method took a third of the time and needed less apparatus and cheaper reagents There had been no accidents with the concentrated sulphuric acid The method was suitable for routine use

Megaloblastic Anæmia of Pregnancy and the Puerperium

Dr C Giles and Dr Eileen M Shuttleworth investigated pregnancy anæmia in 369 patients in Stoke-on-Trent during the twelve months ending Feb 28, 1958 In 67 cases sternal puncture revealed a megaloblastic marrow All patients responded to folic acid Reticulocyte-counts varied from 8% to 33%, and the serum-iron fell after two or three days' treatment 18 out of 53 cases tested had achlorhydria and the fæcal fat was raised in 7 out of 15 patients No seasonal incidence was noted The overall diet during pregnancy was poor in a much higher proportion of megaloblastic anæmias than with other types of anæmia this was particularly evident in the case of meat

Virology and the Clinical Bacteriologist

Dr P N Meenan said that tissue-culture methods of viru isolation had now become so widely used that new agents were constantly being recovered, many of them from apparentl healthy people The clinical bacteriologist had been slow to adopt the newer techniques, perhaps because of an exaggerated idea of their difficulties Using these methods at least 5 viruses of man could be studied, and the value of a hospital laboratory would be enormously enhanced if it adopted such methods The basic equipment was simple a supply of sui able glassware and a deep-freeze cabinet (a secondhand ice cream freezer) for the storage of specimens High-speed centri fuges or even roller-drums were not at first essential Tissue culture media were now standardised and easy to prepare o obtain, simple antibiotic mixtures would eliminate bacterial o fungal contamination For small laboratories the most suitabl tissues were probably trypsinised human amnion or HeL cells, in some laboratories uterus, minced and used as plasma clot cultures, would be more convenient but was not a sensitive

Precocious Puberty due to Chorionepithelioma of th Pineal

Dr J H Stephens, Dr D F Cappell, and Dr J L Emer reported two cases of pineal tumour associated with precociou development in boys

(1) A precociously developed boy of 4 years was admitted wit headache, vomiting, and a tumour of the pineal region This wa treated by X rays, and about 4 weeks later he died suddenly of intra ventricular hæmorrhage At necropsy the cerebral tumour was wholl necrotic but the lungs contained multiple hæmorrhagic nodules wit the structure of chorionepithelioma, from which it was inferred tha the pineal growth was of this nature

(2) *A boy of 10 had signs of somatic and sexual precocity* and mil polyuria About 9 months later nervous symptoms developed, wit diplopia, mild fits, athetoid movements, and drowsiness Examina tion revealed a pineal tumour with hydrocephalus for which a short circuit operation was performed Death followed suddenly from intraventricular hæmorrhage, and necropsy revealed a large hæmor rhagic growth replacing the pineal and invading the adjacent brain substance There were no secondary growths

Despite the known activity of such growths in secreting chorionic gonadotrophin, the development of somatic and sexual precocity was not likely to be attributable to these effects, but it was thought to be similar to that responsible for precocity in other pineal growths—e g, teratomata, and in certain lesions, both tumours and inflammatory or destructive, in the posterior part of the hypothalamus—by the interruption of the inhibitory nervous pathways which control the release *of hormones from the anterior pituitary*

Prophylaxis of Pulmonary Embolism

Dr N M Gibbs had investigated the relationship between venous thrombosis of the lower limbs and bed rest Thrombosis began in two separate and clearly defined sites—namely, the leg and the thigh—where venous stasis was particularly likely A simple apparatus had been designed which afforded complete control of exercise of leg and thigh muscles in patients confined to bed The "soleus ergometer" consisted of a pivoted platform attached to a spring of variable tension The platform was depressed by plantar flexion of the feet and each full movement of the platform was recorded on a meter The apparatus was mounted on an adjustable carriage clamped to the foot of the bed The spring tension and position of the apparatus may be adjusted with regard to height, age, and strength of the patient *An average of 30 recorded acts of plantar* flexion per hour during the waking hours was thought to be adequate in preventing thrombosis

Cytological Observations on Carcinoma

In their study of invasion of tissues by carcinomas, Dr R A Q O'Meara and Mr R D Jackson had applied standard cytological methods to fresh biopsy material Staining of the *Golgi apparatus* had shown different results in humans from those obtained by Ludford[1] in animals In squamous-cell carcinomas it was found that the arrangement of the Golgi apparatus in the normal epidermis corresponded to that found in carcinoma invading the tissues, in so far as the basal cells of the epidermis corresponded to the peripheral cells of invading carcinoma, and the mature cells of the epidermis undergoing keratinisation corresponded to those of the central parts of the carcinoma Thus, in squamous carcinoma, the tumour was maturing by mitosis and keratinisation towards the centre of the growth, while the peripheral cells of the carcinoma were growing outwards into the tissues in the opposite direction. It was found that the peripheral cells, when stained to show mitochondria, appeared to be forming fibrils, which were deposited on the outlying invading cells Sometimes the invading cells were overwhelmed by the deposit and they were then removed by phagocytes, for the most part they thrived and grew outwards into the deposit The fibrils could be found in advance of the main body of the tumour, forming a coagulum in the tissue spaces, thus interfering with the nutrition of the cells of the part and providing the carcinoma cells with an advantage

HEBERDEN SOCIETY AND DUTCH SOCIETY OF RHEUMATOLOGISTS

The Heberden round and a joint meeting of the Heberden Society and the Dutch Society of Rheumatologists were held at Leiden on April 25 and 26

Rheumatoid Arthritis and Pericarditis

Prof J Goslings gave the annual Heberden round at the University Hospital He described 13 cases of pericarditis and rheumatoid arthritis, 3 of which had come to necropsy Most of the patients had severe active rheumatoid arthritis, and some had other visceral involvement Several had the lupus-erythematosus (L E) cell phenomenon In 4 patients pericarditis had been recognised where the duration of rheumatoid disease had been less than eighteen months The clinical recognition of pericarditis might be difficult, physical signs might be transient and the electrocardiogram negative in cases showing pericarditis at necropsy Professor Goslings thought that this difficulty might explain some of the differences in the reported prevalence of pericarditis between patients and necropsy series

Incidence of Fractures

Dr S A Den Oudsten and Dr B Speyer (Rotterdam) had compared the frequency of spontaneous fractures of long bones and crush fractures of the spine in a group of adult patients with severe rheumatoid arthritis, with that in a control group of comparable non-rheumatoid invalids In both groups the age of the patient and the degree of immobilisation contributed significantly to the development of both types of fracture, but no significant difference could be found between the rheumatoid group and the controls Cortisone in the usual therapeutic doses did not seem to increase the incidence of fractures

Latex Fixation Test

Dr H A Valkenburg and Dr C A De Mos (Leiden) had used the 'Latex' fixation test of Singer and Plotz for the diagnosis of rheumatoid arthritis, with certain slight modifications including the use of a glycine buffer (pH 8 2) instead of a borate buffer, and a longer time between preparation and reading of the test A titre of 1 20 was taken as positive, and the test showed good reproducibility Serum samples from 1023 patients and controls were tested Of those with definite rheumatoid arthritis, 86% showed positive reactions, 83% of non-rheumatoid patients and 92% of the normal subjects gave negative reactions When the results were analysed in terms of strong reactions only, the proportion of non-rheumatoid positive reactions was reduced to 3 6%

L.E. Cells

Dr W Hijmans and Dr H R E Schuit (Leiden) discussed the L.E.-cell phenomenon In 2000 patients with various diseases they had discovered 200 positive cases, but only 1 of these positive cases could not be classified as belonging to the group of so-called collagen diseases The hypothesis (as yet unproved) that the L E cell was the result of an immunological mechanism had received strong support from many workers It seemed that nuclear protein, or a part thereof, but not desoxyribonucleic acid, could be regarded as antigen, and the L E -cell factor (a component of L.E globulin) as autoantibody They had shown that the L E -cell factor could react with the nuclei of calf thymocytes and of hen red blood-cells Even if phagocytosis were prevented, the typical "inclusion" bodies could be formed, though of course they were then free and unincluded, and therefore phagocytosis itself was not an essential part of the reaction They had shown that leucocytes would engulf nucleoprotein itself in the presence of L E factor

Leukæmia

Dr E Kruyff (Wassenaar) reported that of 1996 Dutch patients with ankylosing spondylitis treated with radiotherapy, in whom a follow-up rate of over 90% had been achieved, there had been 256 deaths, 25 of which were due to leukæmia or aplastic anæmia—thus confirming the increased incidence of leukæmia after radiotherapy, to which Van Swaay had called attention in 1950 Several instances of leukæmia in patients treated with deep X-rays for conditions other than ankylosing spondylitis had been reported The incidence of leukæmia was steadily rising in the Dutch population as a whole

Aspirin and Occult Blood

Dr L Th F L Stubbe (Leiden) had found occult blood, judged by a positive benzidine reaction, in the stools of about 70% of 180 persons (140 patients, 40 normal controls), to whom aspirin had been administered in tablet or powder form The phenomenon was reproducible in patients who showed it, and the alternation of aspirin with sodium salicylate was followed by the appearance and disappearance of the occult blood from the stools The amount of aspirin taken had little influence on the appearance of occult blood From the strength of the reaction, and from spectrophotometric determinations, it was shown that the positive benzidine reaction was indeed due to blood, and that up to 4 ml a day might be lost in this way This figure exceeded the normal blood-loss of menstruating women, and might be significant in the production of anæmia in rheumatoid arthritis

Reviews of Books

Applied Physiology of the Eye

The late H Willoughby Lyle, M D, F R C S, assisted by T Keith Lyle, C B E, M D, M R C P, F R C S London Bailliere, Tindall, & Cox 1958 Pp 342 45s

The physiology of vision is a subject seldom adequately presented to the undergraduate student, for it includes not only the whole of the processes involved in the formation of retinal images and their appreciation in the visual cortex but also those mechanisms concerned with the maintenance of the ocular circulation, metabolism, and pressure, and the neuromuscular apparatus of ocular movement This is one of the reasons why the average medical graduate finds difficulty in interpreting signs and symptoms of ocular disorder, and it accounts too for the relative seclusion of ophthalmology as a purely postgraduate specialty A textbook of applied physiology of the eye could do much to remedy this defect, and in the 22 chapters of this volume there is much that will enable the student and the aspirant to higher qualifications to interpret physiologically some of the visual disorders he sees

Anatomy must have a prominent place in the discussion of nervous mechanisms, and the fact that this part of the subject is treated descriptively rather than diagrammatically is responsible for its occupying the major part of the text in the chapters dealing with the ocular tissues and the cerebral structures associated with visual processes The parallel physiological explanation is lucid, and it is supplemented by reference to pathological conditions which provide a useful clinical background to the main description The selection of these pathological examples is perhaps in keeping with the eclectic character of the work as a whole, but it does not always contribute to the clinical perspective which the authors evidently seek The emphasis laid on encephalitis lethargica and the omission of tabes dorsalis as a cause of ptosis may be cited as a minor example of this, and the inclusion of episcleritis as the sole example of ocular collagen disease is another

The chapters dealing with cerebellar coordination, the thalamus and hypothalamus, and the VIIIth-nerve mechanisms form stimulating additions to the more purely ophthalmological parts of the text, but it is disappointing that so little space could be devoted to the visual tracts and the fields of vision The omission of any reference to the optical mechanisms of retinal image formation will also be missed by the ophthalmologist in training The short sections on ophthalmological eponyms and the Greek derivation of certain ophthalmological terms, however, form a welcome addition to the bibliography at the end of the book

The Handicapped and Their Rehabilitation

Editor HARRY A PATTISON, M D , F A C P , director of the Potts Memorial Institute, Hudson, N Y Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1957 Pp 944 *112s 6d*

THE rapidity of a patient's return to full activity after an illness once depended on the efforts of only two people—the patient himself and his doctor They will always be the two prime movers in reablement, but this new symposium from America draws attention to the number of allies whose assistance they may now profitably invoke Forty-four writers have contributed, nineteen of them medically qualified the others include physiotherapists, industrial psychologists, social workers, trade-union officials, a chaplain, and even a musician The editor suggests that the help of any or all of these ancillaries may be required to restore a patient to the complexities of modern life

Ten chapters relate to the treatment of particular illnesses (diabetes, tuberculosis, and cardiac diseases, for example), but most of them describe generally applicable rehabilitation methods, including some, such as music therapy and bibliotherapy, which have seldom been accorded separate consideration in this country A comparatively small part of the book is concerned with legislation and administrative details peculiar to the United States

Even allowing for the range of topics it describes, the book gives the impression that each chapter is addressed to a different audience Sometimes (as in the section listing technical faults in cleft-lip repair operations) that audience seems very specialised But many sections, such as an admirable one dealing with epilepsy, are of wide interest Though it does not deal with practical details, or the reablement of individual patients, the book discusses some problems, such as those posed by colostomy and by facial deformity, not mentioned elsewhere , and these sections will help many physicians and surgeons Moreover, in its entirety, the volume will help all those responsible for that coordination of the activities of many specialists which effective rehabilitation requires

The Mammalian Cerebral Cortex

B DELISLE BURNS, M R.C S , assistant professor of physiology, McGill University, Montreal London Edward Arnold 1958 Pp 103 *21s*

THIS monograph, which is the fifth in the present series sponsored by the Physiological Society, discusses only a few selected aspects of its title Those who know Dr Burns' work on the isolated cerebral cortex will not be surprised that this provides a central theme for the book "Isolated cortex" in this context refers to a slab of tissue from the surface of a cat's cerebrum which retains its pial blood-supply but has had all its neuronal connections severed The electrical properties of such preparations are described, and this provides a background for discussion of possible neurophysiological mechanisms which may be involved in activities like remembering and learning and in the interaction of different cortical areas The question whether or not spontaneous activity (here defined as the capability to discharge at moments not dictated by the precise times of arrival of energy from outside) is a characteristic of cerebral neurones is considered at some length without, however, any conclusion other than that the answer is not of immediate importance

Much of the ground usually covered in textbook accounts of the physiology of the cerebral cortex is omitted, but Dr Burns has succeeded well in his declared intention of writing for those "who do not operate oscilloscopes" about particular aspects of neurophysiology which intrigue him Readers whose curiosity is aroused by these topics will find plenty to hold their interest in this clearly written and adequately illustrated book

Polymyositis

JOHN N WALTON, M D , M R C P , first assistant in neurology, King's College, University of Durham, RAYMOND D ADAMS, M D , Bullard professor of neuropathology, University of Harvard Edinburgh and London E & S Livingstone 1958 Pp 270 *32s 6d*

THE authors review the group of disorders which includes dermatomyositis, scleroderma, generalised myositis fibrosa, relapsing myositis, and calcinosis universalis, and add 40 new cases of polymyositis of which 25 were seen by one or both authors They describe the clinical picture and differential diagnosis, paying particular attention to the points of distinction from muscular dystrophy, notably the presence of weakness of the neck muscles and sometimes of swallowing in polymyositis Skin lesions may be a valuable aid to diagnosis, but they are by no means necessary to the diagnosis The differential diagnosis is of importance because patients with polymyositis may benefit from corticoids The book is full of valuable references to the literature, but so much detail is given that it is not an easy book to read, and the salient features may be lost in detail

---

Frazer's Anatomy of the Human Skeleton (5th ed London J & A Churchill 1958 Pp 247 50s)—Dr A S Breathnach's revision of Prof J E Frazer's classic will appeal to anatomists, and to surgeons training for the primary fellowship It is 18 years since the last edition, and much recent work on the development and growth of bone has been included. Dr Breathnach has, however, wisely maintained the original qualities of the book, which still offers the best text in descriptive osteology Frazer's illustrations remain largely untouched. Though not attractive in style, they are so clear and accurate in relating soft parts to bones that it would not be easy to improve them A few new drawings and, for the first time, radiographs have been added There has been some rewriting, and this has improved the text, we hope that it will be extended in later editions A wider bibliography would have made the volume more valuable to professional anatomists Like many texts of descriptive anatomy, it is parsimonious in functional interpretation of structure, and an addition of a few pages would invigorate and illuminate Old favourites like the arches of the foot are mentioned, but ribs are still chiefly a protection to viscera, we tour the orbit and leave it with no views on its functional appropriateness, the femur is long, but we are not told why If anatomists do not give some time to the significance of gross anatomy, who will ?

The Door of Serenity (London Faber & Faber 1958 Pp 119 21s)—This book by Dr Ainslie Meares describes and illustrates by a series of 24 coloured plates the stages of a lengthy and eventually satisfactory psychotherapy of a young schizophrenic girl Jennifer, as she is called, was 19 when first seen by Dr Meares, and the usual types of treatment proved unsuccessful She then began to bring him paintings, and over the next few years produced over 200 of these, from which he was gradually able to learn and interpret to her the root causes of her illness The book is not a complete or detailed case-history, but an outline of an interesting voyage of discovery undertaken by patient and therapist together

THE LANCET
LONDON 17 MAY 1958

American Reactions to the Staphylococcus

LIKE ourselves our American colleagues are worried by the high incidence of staphylococcal sepsis.[1] They note that reports of the same problem come from what they describe (apparently without intended irony) as "all medically advanced parts of the world". With characteristic energy and thoroughness, the American Medical Association, supported by sixteen other influential agencies, convened a conference of experts to discuss all aspects of the problem at Cleveland on Nov. 14, 1957. The essentials of the conference have now been published.[1,2] The experts remarked on the widespread dissemination throughout the hospitals of the United States and Canada of highly virulent, readily communicable, antibiotic-resistant strains of *Staphylococcus aureus* with a tendency to produce nasal carriers, skin lesions, wound sepsis, soft-tissue infections, and pneumonia. Neonatal infections and breast abscesses among nursing mothers were especially noted as troublesome to the sufferers and likely sources of spread of dangerous staphylococci to the general population. The conference thought that the situation arose from a tendency to relax the rigorous aseptic precautions which should be observed in hospitals and to rely instead on prophylactic administration of antibiotics. Vigorous investigation followed by rigorous measures often controlled infection in particular hospitals for the time being. Nevertheless, the conference considered that the troublesome hospital staphylococci had a special propensity for becoming resistant to a wide range of antibacterial agents, including leucocytes. It was on no less certain ground in proclaiming that we lack basic information about the ecology, pathogenesis, immune relationships, and variability of staphylococci —our knowledge of these matters being much poorer for staphylococci than for streptococci, pneumococci, and other pyogenic microorganisms. The conference recommended encouragement and money for research into these matters, and it suggested that every hospital should charge a responsible officer or committee with the investigation, control, and prevention of infections within the hospital. The whole community was advised to tackle the problem of spread of staphylococcal infection beyond hospitals through medical societies, local health departments, and inter-hospital committees on infections.

Of the need for some such actions there can be little doubt. How many hospitals in our own country are confident about the efficacy and safety of their sterilising and laundry procedures? How many provide clean air, or even abstain from doing operations and wound dressings in air that is richly charged with pyogenic bacteria? How many hospitals have effective procedures for checking whether members of staff with septic lesions on their persons are going about their duties and operating on, or otherwise attending to, patients whose tissues may have a lowered capacity to resist infection? In how many hospitals are junior medical staff or even nursing staff left to prescribe whatever antibiotics they happen to think might be useful? To what extent are antibiotics needlessly used as prophylactics in circumstances where the probability of sepsis is less than the risk of poisoning or sensitising the patient or producing another focus of antibiotic-resistant microorganisms? In practice, we regularly transgress in all these aspects of hospital routine. Defective sterilisers blow steam around without certainly producing sterile dressings. Laundries contaminate articles that were formerly free of pathogens. Hospital air is sucked from anywhere to anywhere else—even through the sterilised dressings inside sterilisers. Ward maids with pan and brush sweep rooms in which mothers put their infants to the breast. Nurses make beds immediately before or even during dressing rounds. Fluffy woollen blankets provide warmth scarcely needed in centrally heated hospitals; they cannot be sterilised or even very often washed without ruining them, and they fill the air with bacteria-laden dust. Nurses with boils on their noses remain on duty because they do not know the menace that they carry to their patients. Chiefs with an optimistic assurance that they have no trouble—whoever else may have it—leave instructions with sister to "give an antibiotic if it is needed". In the midst of all this, the bacteriologist may lecture, the superintendent may feel vaguely worried, the matron may consider that polishing is not enough, but—in the absence of flagrant disaster—nobody has power to act. Nobody, in all probability, even knows or can ascertain the exact rate of cross-infection in his own hospital. Probably things are at their worst in big hospitals with many separate units under distinguished chiefs. Disagreeable facts are not always revealed to the chief; to his eye all appears to go well. Terrible things, it is rumoured, happen downstairs and up above—but not here. And so the menace continues.

In considering which of the American proposals are applicable to our own situation, we hesitate to urge more sittings of committees or more committees. Many hospitals now have cross-infection committees. There should be one in every hospital, for its educative value may be considerable. But probably the general establishment of the post of hospital infection officer will have to be considered. Such a person should be senior in years and of consultant status. All infections, however trivial, should be reported to him, and he should see that they are properly investigated and the results recorded. He should be encouraged to go everywhere and probe everything that strikes his mind as possibly in need of investigation. He should systematically make the results of his work known to people concerned and to the medical and nursing staff as a whole. He should keep the administration in mind of its duty to provide a clean and wholesome hospital. Education and propaganda may accomplish some useful results, but they are not sure enough When it is important to ensure results responsibility must often rest with a single person That is why we now advocate the appointment as hospital infection officers of men of the highest professional and personal qualities This action has long been advocated by COLEBROOK,[3] and we believe that it is now required in order to control the increasing scandal of hospital cross-infections —a scandal which we seem unable to prevent by the gentle processes of self-education and self-discipline

Extracorporeal Circulation

> " THE real key to further advance in the surgical treatment of established cardiac defects will only be provided by some simple and efficient method of maintaining the cerebral circulation while the heart is temporarily out of commission Naturally there are many other problems of a more local nature for solution but, so long as the surgeon is faced with the certainty of irreparable cerebral damage if he interrupts the circulation for any appreciable period, he has little incentive to devise operative procedures which can never be carried out "

THE late LAWRENCE O'SHAUGHNESSY wrote these words in 1939,[4] and they were repeated by Dr JAMES WATT, director of the National Heart Institute of the U S Public Health Service, in his opening address to the Conference on Extracorporeal Circulation in Chicago in September, 1957 O'SHAUGHNESSY recognised the ultimate need for extracorporeal circulation at a time when even closed operations on the heart were little more than a theoretical possibility He described some of his early experiments in animals with a perfusion apparatus, and clearly appreciated the essential part that was to be played by animal experiment

Following the work of a few pioneers in this country, in Sweden, and in the United States, the possibilities implicit in the successful application to man of the methods of extracorporeal circulation have been widely realised, and in the past three years a tremendous surge of enthusiasm has resulted in the cure of many patients During this period of development a vast quantity of experimental data—animal, biochemical, technological, and clinical—has accumulated and rival schools of technique were beginning to emerge In March, 1957, the surgical study section of the National Institutes of Health of the United States Public Health Service were asked by the National Advisory Heart Council to organise a conference on a world-wide scale to bring together workers in this field The conference, held in Chicago in September, was most successful, and a full report of its proceedings has just been published in this country[5]

Among all the scientific data may be found clinical results of great excellence J W KIRKLIN, for example, reports from a total of 245 cases no deaths due to perfusion in the last 39 patients and DE WALL from a slightly greater number of cases only 1 death from any cause in the last 40 patients, most of whom can be considered cured Such good results from these experienced workers were not obtained early in their series KIRKLIN reports 6 deaths in the first 10 patients and a further 6 deaths in the succeeding 27 While some of these early deaths could now be avoided even by the inexperienced, because the causes are becoming clear, it seems inevitable that such a complex procedure will continue to carry a high initial mortality Proper selection of cases will undoubtedly help to improve results, the selection of early cases is a grave responsibility for physician and surgeon alike

The general methods of perfusion and surgical technique are now established, and both apparatus and operative procedures are being constantly improved The goal of a really satisfactory oxygenator using diffusion of respiratory gases through a membrane is still distant, but it may have been brought a stage nearer by the report from Dr MELROSE and his colleagues on p 1050 The difficulties are partly mechanical (namely, in providing a surface area of membrane comparable to that in the human lung) and partly physiological (namely, in securing a material for the membrane which is innocuous to blood, is readily sterilised, and has the necessary diffusion characteristics for respiratory exchange)

It is becoming increasingly apparent that progress in this field is expensive The National Advisory Heart Council in the United States has approved grants of over $700,000 for future use in research on extracorporeal circulation, and this is over and above money derived from the universities and private benefaction In this country funds for research have been derived principally from the universities and from the Nuffield Foundation, but, with the reliability of oxygenators established, the main charge should fall henceforth on the National Health Service The need now is for a few teams, well supported technically, working constantly together clinically and in the laboratory

Modified A I D.

THERE has lately been heightened interest in the legal and moral issues raised by artificial insemination with donor's semen (A I D) for solving the problem of the childless couple where male infertility is the cause Clearly A I D is open to weighty objections, and any alternative method deserves careful consideration At the Hadassah University Hospital in Jerusalem Dr S ROZIN has been testing a modified technique of artificial insemination[6] ROZIN obtained semen samples from infertile husbands and separated the spermatozoa from the plasma The spermatozoa were then suspended in plasma obtained similarly from a normal donor's semen Five women of childless marriages were inseminated with their husband's spermatozoa suspended in this way and two of them became pregnant Firm conclusions obviously cannot be based on such limited figures, but ROZIN's idea merits some discussion

Successes with this method would be open to at least two explanations—namely, that donor spermatozoa were accidentally included in the material used for insemination, or that abnormality of the plasma of the infertile semen impaired the normal function of the spermatozoa Complete removal of spermatozoa from semen by centrifugation is remarkably difficult Centrifugation sufficient to produce a dense pellet of spermatozoa and other particulate bodies at the bottom of the tube may still leave actively motile spermatozoa suspended freely in the supernatant plasma The presence of these cells may go unsuspected, for the dilution of the spermatozoa is so extreme that their detection under the microscope requires patient examination It is reasonable to suppose that the spermatozoa that remain suspended in the plasma are there chiefly because they were among the most actively motile cells in the sample population Centrifugation may therefore have selected the most vigorous and presumably potentially the most fertile spermatozoa of the donor's semen, and their presence would constitute a very special hazard if the plasma were employed by ROZIN's method Abnormality of the plasma of infertile semen might manifest itself as a deficiency of some normal component, but it is most unlikely that lack of a normal constituent per se could underlie failure of spermatozoa to initiate conception, for pregnancy can be obtained by inseminating spermatozoa recovered from the epididymis and suspended in physiological-saline solution[7] On the other hand, deleterious effects on spermatozoa may conceivably result from gross imbalance of plasma composition, from a normal plasma constituent in abnormally high concentration, or from a foreign toxic substance in the semen These possibilities are largely hypothetical, and much work is still needed to establish their occurrence and practical significance

[5] Extracorporeal Circulation (edited by J GARROTT ALLEN) Springfield Ill Charles C Thomas Oxford Blackwell Scientific Publications 1958 Pp 518 57*s* 6*d*

[6] See N Y *Times*, April 14 1958

Many observations have been made on conditions affecting spermatozoa in vitro[8], and it is known that they are, on the whole, more resistant than most body cells to changes in physical and chemical environment Motility is, of course, abolished if conditions depart sufficiently from normal, and it is reduced by metabolic enzyme inhibitors Usually spermatozoa recover their motility if removed from the medium containing the inhibitor before too long a time has passed and are placed in a medium lacking inhibitory effect Recovery occurs perfectly well in artificial media, and therefore does not depend on the presence of any constituent of the male accessory secretions Broadly speaking, fertility is correlated with motility[9 10] Generally, fertility is lost before motility, and PARKES[11] and PARKES et al[12] have shown loss in this order to be especially constant following the use of certain enzyme inhibitors, which remove fertility without greatly affecting motility WERTHESSEN et al,[13] in a study of seminal properties and fertility in stud stallions, exchanged the spermatozoa and the seminal plasma of several animals and noted that the plasma of different animals differed in its capacity to maintain spermatozoon motility Maintenance of motility was inversely correlated with the concentration in the plasma of non-protein sulphydryl compounds, which evidently exerted a deleterious influence on the spermatozoa Further investigations showed that fertility also was inversely associated with the concentration of these compounds Finally, the investigations were extended to man, and here again the concentration of non-protein sulphydryl compounds, though much lower than in stallion semen, was inversely correlated with motility maintenance WERTHESSEN et al infer, therefore, that in man, too, the sulphydryl concentration may be inversely related to fertility

Thus in the human male infertility may sometimes be due primarily to abnormality of the seminal plasma, and this abnormality may possibly take the form of unusually high levels of non-protein sulphydryl compounds If this were proved to be so, remedial measures would involve removal of the spermatozoa from their native plasma Insemination would require resuspension of the spermatozoa in another medium, but this need not necessarily be seminal plasma unless the damage suffered by the spermatozoa could be repaired only by a specific factor in normal semen Meanwhile much further research is clearly needed

A NEW AUSTRALIAN MEDICAL SCHOOL

IT is exciting to contemplate the long-overdue rebuilding of some of the medical schools in this country—for example, at Liverpool, as we report on p 1066 But how much more exciting to welcome a completely new school! Men and women of Western Australia wishing to study medicine have had to leave their home State, usually for Adelaide, for the preclinical and clinical years, and in 1955 the Government decided to establish a medical school at Perth—provided that the university could show that public opinion was in favour by the stringent test of raising £400,000 by appeal (the population of the State is less than 700,000) The result of the appeal was unequivocal, for more than £500,000 was subscribed, and plans for a new school were begun, and on April 10 Sir Charles Gairdner, the Governor, formally opened it.

The faculty of medicine is the ninth in the university Teaching began with the academic year in 1957, when a first-year class of 85 students was enrolled, and 16 Western Australian students who had been studying at Adelaide began their sixth-year work at Perth The departments of anatomy, physiology, and biochemistry began teaching in March

The school buildings are not yet complete, but more interesting than the prospects of new buildings are the prospects for teaching and research In designing its teaching programme the new school is doubly free, for not only has it no traditional curriculum but also it begins work at a time when the General Medical Council has relaxed its detailed control and permits experiments Until 1957 the Council had been precise and detailed, and while its influence had certainly maintained an adequate standard of education in English and Australian medical schools, it had tended to stifle individual enterprise in the framing of new forms of teaching or new approaches to the medical curriculum " Today the staff have an opportunity for boldness For research there is ample money available, since, besides several bequests made in the years before the appeal and a gift to establish a research foundation (primarily for investigation of cardiovascular disease), £250,000 of the appeal moneys has been set aside for research and special projects, and the balance, beyond the sum needed to establish the school, has been used to form a permanent endowment fund We send our greetings and good wishes to all concerned in the new school

HYPERTENSION DUE TO RENAL-ARTERY STENOSIS

ANY lesion which significantly narrows a renal artery may induce hypertension This type of hypertension is important particularly because it may be relieved by restoring an unobstructed blood-flow to the kidney, or by nephrectomy if the disease is unilateral[1] It has long been recognised that such conditions as unilateral atrophic pyelonephritis may be associated with reversible hypertension, but that stenosis of the main renal artery can cause increase of blood-pressure has become apparent only in the past few years A renal humoral mechanism, similar to that demonstrated by Scott and Bahnson,[2] in thoracic coarctation of the aorta, is thought to be responsible Hypertension due to unilateral renal arterial stenosis differs, however, from that due to coarctation in that the contralateral kidney is exposed to the full effects of the disease

Although few instances of hypertension associated with renal-artery stenosis have been reported, a surprising variety of lesions has been noted in young people congenital stenosis and other anomalies of the renal-artery, aneurysm of the renal artery, and coarctation of the abdominal aorta, in older patients atherosclerosis, trauma, compression, thrombo-angiitis, and embolism of the renal artery

The symptoms and signs of this type of hypertension are unfortunately no different from those of other types the diastolic level is high and stable, and signs and symptoms progress rapidly Diagnosis is therefore not easy and depends essentially on arteriography It would obviously be unwise and unnecessary to subject every hypertensive patient to renal arteriography, and much judgment is needed to select patients for this elaborate investigation DeCamp and Birchall[3] advise arteriography in all patients whose hypertension develops (in the absence of primary renal disease) before the age of 25, and in all in whom persistent severe diastolic hypertension comes on after the age of 50—similar recommendations to those of Poutasse and Dustan[4] In the intervening age-groups they undertake aortography if there is something in the history which does not conform to the normal pattern of essential hypertension It is important to exclude as far as possible a phæochromocytoma before aortography, as the injection may provoke a fatal hypertensive attack In the adult aortography is performed by translumbar puncture of the aorta just above the mouths of the renal arteries if placed too high the dye escapes into the other major aortic branches and the renal vessels are not plainly seen In children the dye may be put in retrogradely by catheterisation of the femoral arteries

Adequate renal circulation may be restored by excising the strictured area and reconstructing the artery by end-to-end suturing, by endarterectomy, or by using the splenic artery as an end-to-side anastomosis DeCamp and Birchall[3] believe that, with arteries of the size of the renal, free grafts (homografts or synthetic) are best avoided Freeman[5] followed three cases in which the renal artery was occluded during endarterectomy for aortic thrombosis, the grumous material being accidentally forced into the orifice of a renal artery In one of the patients severe hypertension developed but subsided after nephrectomy

Aortography during investigation of high blood-pressure would be advised more commonly if the technique was free of complications Huger et al[6] have attempted to minimise the risk of renal parenchymal damage, during the flooding of the kidney with dye, by giving an intra-aortic injection of procaine before the dye There is evidence that in dogs this gives some protection, but in man this is less clear, and two other factors are much more important—the site of injection and the dose of contrast medium The constant factor in reported cases of severe bilateral renal damage has been the large dose of concentrated organic iodide used Renal arteriography should be done with 30 ml or less of one of the less toxic dyes, such as sodium diatrizoate (' Hypaque '), with such a quantity the risk of parenchymatous damage is very slight

THESAUROSIS

ANOTHER foreign body is being added to our reticulo-endothelial system's treasure chest Bergmann et al[7] report the case of a 27-year-old receptionist who had mild malaise and increasing fatigue for two or three months and was admitted to hospital with a chest radiograph which showed bilateral fuzzy hilar enlargement and reticulated infiltration of all parts of both lungs A general examination six years before had included a chest radiograph, which had been entirely normal Physical examination and many tests all yielded normal results except for the chest picture Resection of the right scalene fat pad produced three moderately firm lymph-glands, one of which yielded no organisms on a wide variety of cultures Histological examination of the other two showed pronounced hyperplasia of large epithelioid cells with occasional giant cells Again no organisms could be found, nor was there any fat in the cells of the granulation tissue There were, however, round granules in the epithelioid cells and interstitial tissue The only foreign body which could be incriminated was a hair-spray which the patient had used for two years, during the last six months of which her hair had been sprayed twice daily After the use of the spray was stopped, radiographs of the chest showed partial clearing of the infiltration and lymphadenopathy in two months and a normal picture after four months Shortly before this, a 22-year-old married woman had been seen as an outpatient because of an abnormal chest radiograph found on routine examination there was extensive bilateral reticulated infiltration of both lung fields and enlarged lymph-nodes in both hilar regions, but the patient was in good health and denied any respiratory symptoms A pre-employment radiograph two years earlier had been normal When nothing else could be found to account for the conditions, the patient was asked about inhalants She had used a hair-spray almost daily, sometimes twice a day, for about three years Two months after stopping the use of the spray, radiography showed regression, and another month later the picture was virtually normal

These stories seem simple in retrospect, but consternation was caused by the discovery of an apparently serious, widespread infiltrative process in the lungs in supposedly healthy young women Bergmann et al could not determine the exact nature of the particulate matter found in the lymph-glands in the first case They evaporated to dryness 20 ml quantities of hair-spray, suspended the residues in saline solution, and injected the suspension subcutaneously into guineapigs One to two months later the sites of injection showed granulomatous lesions in which particulate matter was found in foam cells, and similar granules were found sometimes in liver, spleen, or lung The reaction was typical of the macromolecular substance reaction[8] given by the various natural and synthetic resins used in cosmetics as well as for many other purposes While most of these substances are chemically inert, and relatively large quantities may be stored in the reticulo-endothelial system without affecting function, there is always the possibility that one may be carcinogenic[9], and the diagnostic difficulties to which they may give rise should be generally recognised

DETERMINING PROTEINS IN LOW CONCENTRATION

THE most accurate methods for determining the relatively small amounts of protein that may be present in biological fluids, such as urine and cerebrospinal fluid, involve either gravimetric estimation after precipitation, or estimation of the nitrogen content of the precipitated and washed protein by the micro-Kjeldahl technique But these methods are time-consuming and thus unsuitable for use in busy routine laboratories All the methods in routine use sacrifice, to some extent, accuracy for speed They depend either on estimation of the volume of the precipitated protein, as in the unsatisfactory Esbach method, or, better, on precipitation of protein and comparison of the resulting turbidity with turbidimetric standards, or, better still, on comparison of the colour developed in the biuret reaction with that developed by a standard biuret or standard protein solution This last method usually gives an answer within 5% of that given by a micro-Kjeldahl technique[10] The error of the turbidimetric methods is usually less than 10%, but occasionally may be as high as 20%[11] The Esbach method may give results varying from half to twice the true amount[12]

Closs[13] has described a new reagent for precipitating urinary proteins, which are then determined turbidimetrically in a photoelectric colorimeter The reagent is an 0 2% solution of sodium polythionate brought to a pH of about 2 1 ml of urine is mixed with 10 ml of reagent in the cold, and the turbidity produced after 30 minutes can be assessed qualitatively or estimated quantitatively The reagent is made freshly each week from a stock solution, which will keep indefinitely at room-temperature Closs finds that, qualitatively, the method is as sensitive as Heller's test, which will detect 7 mg of protein per 100 ml[14] Quantitatively the method, applied to urinary protein, appeared to agree somewhat more closely with the micro-Kjeldahl technique than is usual with turbidimetric procedures Its usefulness in determining the protein content of other biological fluids has yet to be ascertained

This method has certain small advantages, in that the amount of fluid required is 1 ml or less, the degree of dilution reduces the error that may arise with initially turbid urines, no heating is necessary, and interfering precipitations or colorations are rare

SURVEY OF CHILDREN

IT is a matter of common clinical experience that infants and children from poor homes do not thrive as well as the socially better favoured But the precise effects of social conditions on physical and mental health and development are not easily defined A study by Douglas and Blomfield[15] provides much long-awaited material

The starting-point of the work was the investigation by the Population Investigation Committee and the Royal College of Obstetricians and Gynæcologists into the circumstances and costs of all confinements in Great Britain during the first week of March, 1946 Of the 14,000 families involved in that inquiry[16] 5000 children were selected for longitudinal study, and it is their life-stories up to the age of 5 that Douglas and Blomfield are now concerned with

These children spent their early years in the unsettled post-war era and have been subject to the manifold social changes of the time, not least of which was the inception of the National Health Service when they were 2 During the survey period (1946–50) housing conditions steadily improved, and many of the families moved upward in the social scale This background has to be remembered in assessing some of the findings of the survey, or in extrapolating conclusions for present-day needs

Poor social conditions showed differing effects according to the age of the child In the perinatal period such conditions were associated with an increase in prematurity and neonatal death, in infancy with early and severe respiratory infections, and in childhood with significant depression of growth At all ages the direct cause of socially determined disorders was "maternal inefficiency" with poverty, overcrowding, and large families appearing as predisposing factors The report shows clearly that successful mothering of a large family, where the housing conditions are poor and the budget is slender, requires care, resourcefulness, education, and supportive advice The best showing was made by the families of "black-coated workers" As a group they are not materially better favoured than skilled workers, but by care, ability, and utilisation of child-welfare services they achieve not only favourable development for their children but also often fulfilment of their social aspirations

Douglas and Blomfield feel that "the social and educational approach" offered by the local-authority child-welfare services has done much to improve standards of maternal care, and that this is " still of primary importance in the saving of infant life " They urge that the existing services be retained, with some reorganisation, saying that the time is not yet ripe for their disbandment But it must be noted that in the survey material the incidence of fatal illness was highest before treatment by family doctors became available to all without fee under the N H S , that the incidence of infections (without regard to severity) in all but the highest social groups was no lower among the " careful " mothers, and that schoolchildren and chronically infected adults were important spreaders of family infections Moreover, the infant-welfare clinics failed to attract the mothers most in need of their services

Other matters no less important are illuminated by the study The possible ill effects of separation, family breakup, and the employment of mothers were investigated Although the inquiry was necessarily superficial, no convincing evidence appeared that these had any adverse effect on the physical or emotional wellbeing of the children There was some suggestion that when the separation involved admission to hospital neurotic symptoms increased Victims of accidents tended to be superior children, indicating the inevitable risks incurred by those with a healthy body and adventurous spirit The findings on toilet-training confirm the impression that girls more quickly acquire continence than boys Enuresis is strongly associated with poor maternal care, and early pot training within a secure home is followed by the most rapid attainment of sphincter control This is contrary to the often-expressed view that early potting is a manifestation of coercive training likely to be followed by failure and neurosis

The Institute of Child Health (University of London), the Society of Medical Officers of Health, and the Population Investigation Committee are to be congratulated on sponsoring this study It is good news that the Nuffield Foundation have made a grant to enable the study to continue until the children reach the age of 15

THE BONE CRYSTAL COMPLEX

PROGRESS in work on the structure of bone has been reviewed by McLean[1] The histological unit is the osteon—the Haversian system with canal, concentric bony lamellæ, cells, and canaliculi—150 µ in diameter and several millimetres in length Throughout adult life there is a constant process of " Haversian remodelling " of compact bone, at any given time a certain amount of labile reactive bone—about 1% of the total mass of bone—is present, and it is this 1%, actively exchanging substance with the surrounding tissue-fluids, that makes bone a living and not a dead material The organic unit of bone is the collagen fibril—800Å made up of macromolecules secreted by the osteoblast The inorganic unit is the rod-shaped bone crystal—$3Ca_3(PO_4)_2\ Ca(OH)2$, hydroxyapatite—about 200Å long and 75Å in diameter The crystals are oriented in the long axis of the collagen fibril and packed round the region of the periodic cross-banding, leaving uncovered gaps along the fibril[2] Owing to their minute size the crystals have an enormous surface-area per unit of mass—of the order of 200–300 sq m per gramme It is thus expanse of crystal surface that gives bone its most important non-mechanical function—the " homeostatic regulation of the ionic composition of the circulating fluids of the body, and a reservoir of th calcium ion "[3]

Around each crystal, and partly bound to its surface, a layer of hydrated ions together with a " shell " of wate Each gramme of crystal, it is claimed, can hold 0 8 g of water in this way, and so there is a greater volume o water than crystal Any ion from the surrounding flui can diffuse into the water shell The layer of hydrate ions—calcium, phosphate, and hydroxyl—is constantl exchanging with similar ions in the surface layer of th crystal lattice, and there is a much slower ionic interchange between the surface and the interior of th crystal Of the ions circulating in the body-fluids K^+ and Cl^- can penetrate only as far as the hydration shell Na^+, UO_2^{++}, CO_3^{--}, and citrate^{---} can displac calcium phosphate or hydroxyl ions from the crystal lattic surface, while Ca^{++}, Sr^{++}, Ra^{++}, PO_4^{---}, and F^- ca penetrate into the interior of the crystal structure Such ionic movements take place wherever body-fluids are i contact with the crystal complex of reactive bone As the crystals age and increase in number, they displace th water and so become dehydrated and inert like natura mineral deposits

Some quantitative data on interchange of ions between blood and bone have been obtained by means of radioactiv isotopes such as ^{45}Ca, ^{32}P, and more recently ^{47}Ca External counting gives approximations of the magnitude and rate of this exchange For instance, it is known that in young animals the total calcium in the blood (10 mg per 100 ml) is replaced,every minute

Equilibrium between the blood and the reactive bone of the mineralising osteon is maintained by constant adjustment through ionic interchange between bone, extracellular fluid, and serum This immediate control mechanism may, it is believed, also involve bone-cell activity, with the formation of citric acid, which acts as a carrier and conveys calcium from bone to blood-stream The level of citric acid in bone is influenced by parathyroid and vitamin D[4]

In addition to the minute-by-minute regulation the parathyroid glands are essential for the maintenance of the plasma-calcium at the physiological level of 10 mg per 100 ml If the parathyroid glands are removed the calcium level falls to 7 mg per 100 ml , and with parathyroid hyperactivity it may rise to 15 mg per 100 ml Parathyroid reaction to changes in calcium-ion concentration is effective in terms of hours, compared to the more immediate results of ionic transfers, and is brought about by the dissolution of mineral from the stable bone—probably by the activity of mobilised osteoclasts[5]

More work on the electron microscopy of bone is required—particularly with regard to the disposition of the bone crystals, the fine structure of the ground substance, and the study of radio-isotopes at the level of ultrastructure

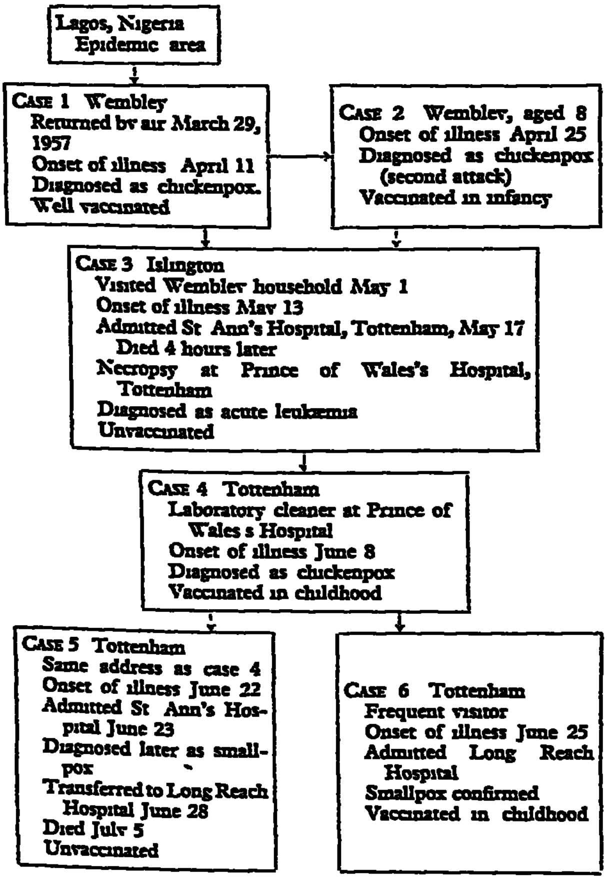
G DONALD W MCKENDRICK
M A , B M Oxon , M R C P
CONSULTANT PHYSICIAN IN INFECTIOUS DISEASES,
ST ANN'S HOSPITAL, TOTTENHAM

C GRANT NICOL
M.B Lond , D.P H , Barrister-at-Law
MEDICAL OFFICER, MINISTRY OF HEALTH

LOOKED at in retrospect and in the accompanying graphic chart, the smallpox outbreak in Tottenham in the summer of 1957 appears small and neatly disposed of as an epidemiological study This does not mean, however, that the incident was not a full-scale exercise in accepted methods of investigation and control, or that it was without clinical, social, and administrative features of special interest. What may not be so easy to explain is why the disease did not spread more widely despite the measures taken



Lagos, Nigeria
Epidemic area

CASE 1 Wembley
Returned by air March 29, 1957
Onset of illness April 11
Diagnosed as chickenpox.
Well vaccinated

CASE 2 Wembley, aged 8
Onset of illness April 25
Diagnosed as chickenpox (second attack)
Vaccinated in infancy

CASE 3 Islington
Visited Wembley household May 1
Onset of illness May 13
Admitted St Ann's Hospital, Tottenham, May 17
Died 4 hours later
Necropsy at Prince of Wales's Hospital, Tottenham
Diagnosed as acute leukæmia
Unvaccinated

CASE 4 Tottenham
Laboratory cleaner at Prince of Wales's Hospital
Onset of illness June 8
Diagnosed as chickenpox
Vaccinated in childhood

CASE 5 Tottenham
Same address as case 4
Onset of illness June 22
Admitted St Ann's Hospital June 23
Diagnosed later as smallpox
Transferred to Long Reach Hospital June 28
Died July 5
Unvaccinated

CASE 6 Tottenham
Frequent visitor
Onset of illness June 25
Admitted Long Reach Hospital
Smallpox confirmed
Vaccinated in childhood

Foremost in the experience gained was the sense of close cooperation which existed from the moment the first case was suspected, and remained throughout subsequent events, between the Ministry of Health, the North East Metropolitan Regional Hospital Board, the Virus Reference Laboratory, Colindale, the members of the panel of smallpox opinion, local hospitals' medical and administrative staffs, general medical practitioners, and the medical officer of health's department.

The Early Stages

By telephone at 10 15 A M on Friday, June 28, 1957, the medical officer of health (G H H) was informed by the consultant physician for infectious diseases (G D McK) at St. Ann's General Hospital, Tottenham, of a case of suspected smallpox in that hospital

An unvaccinated boy aged 6 (case 5), had been admitted to the poliomyelitis unit of the hospital on June 23 with a history of backache, fever, abdominal pain, and vomiting On admission he was ill, with abdominal tenderness and guarding, and a temperature of 102°F He had general ichthyosis and superimposed patches of eczema The practitioner's provisional diagnosis of poliomyelitis was not borne out by this further examination, which suggested an acute abdominal emergency At laparotomy the appendix (which was removed) was found to be normal, but the mesenteric glands were seen to be enlarged During the next three days the patient remained febrile and ill, and there was some bleeding around the abdominal wound On admission a few macules had been noted in the interscapular area, and by June 27 it was evident that he had a rash, predominantly papular and peripheral, besides the chronic skin condition. At the time eczema herpeticum was thought to be more likely than smallpox, but skin scrapings and fluid from one or two vesicular lesions were sent to the Virus Reference Laboratory, Colindale

Next morning there was a striking change in the child's appearance The rash was vesicular and becoming confluent, and smallpox could be confidently diagnosed on clinical grounds Following the telephoned report of these facts to the medical officer of health, an immediate consultation was held at the hospital, when it was agreed to call in a second member of the panel of smallpox opinion (Dr A M Ramsay) and to report the situation by telephone to the principal medical officer of the epidemiology division of the Ministry of Health (Dr W H Bradley) Before noon both Dr Ramsay and a medical officer from the Ministry (C G N) had arrived at the hospital and agreed to the clinical diagnosis of smallpox Arrangements were made for the immediate transfer of the patient to Long Reach Hospital, Dartford, under the care of the late Dr M Mitman During the same day a preliminary report was received from the director of the Virus Reference Laboratory (Dr F O MacCallum) that the complement-fixation test was strongly positive for variola-vaccinia On July 5 the boy died Throughout his stay at St Ann's Hospital he had been barrier-nursed in single cubicles—for the first four hours in the poliomyelitis unit and for the remainder of the time in another cubicle block

Before the clinical diagnosis had been confirmed, his parents had been interviewed by the chief public health inspector (Mr E T Jenkins) and detailed information of the members of the household and their occupations obtained The father, a bus conductor, had reported at his depot that morning, since this was an obvious risk the medical officer of health at once spoke on the telephone to the chief medical officer of the London Transport Executive

This early inquiry into the home circumstances revealed a further case of smallpox, the boy's grandmother (case 4) living in the same house and by this time convalescent

This patient, vaccinated in childhood and now aged 61, had fallen ill on June 8, a rash (which was thought by her doctor to be that of chickenpox) developed on June 12 She was seen by two of us (G H H and C G N) in consultation with Dr Ramsay The clinical findings were equivocal but consistent with a modified attack of smallpox In view of the satisfactory vaccinal state of the rest of the household, now refreshed by further vaccination, it was considered justifiable to await the result of laboratory examination of scrapings taken from the most suitable of the few remaining lesions To complete this patient's subsequent history, the complement-fixation test was reported as positive on the following day, when she was removed to Long Reach Hospital, and a positive egg culture was reported as further confirmation two days later This patient continued an uninterrupted convalescence and was in due course discharged from hospital

From the chief public-health inspector's inquiries, it was learned that the patient was employed as a domestic worker in the pathological laboratory at another hospital in the Tottenham group of hospitals—a circumstance which it was felt must afford some explanation of her infection (This matter is referred to later in the account of the outbreak)

ACTION TAKEN AT ST ANN'S HOSPITAL

It was agreed that immediate responsibility for vaccination and other control measures at St Ann's Hospital should be undertaken by one of us (G D McK) who had arranged for the supply of enough lymph to vaccinate the whole complement of the hospital, and for the preparation of a list of all primary contacts on the staff with their vaccinal history and that of the other patients on the two wards in which case 5 had been nursed

There were 42 primary contacts among the staff and 31 patients in the two wards, only 6 of the patients had been vaccinated Permission to vaccinate these children was sought by telegram and all but 2 were vaccinated within twelve hours—the remaining 2 being vaccinated next day when permission was received

When we discovered the inadequate vaccinal state of the children nursed in the cubicles adjacent to case 5, we decided to give them hyperimmune anti-variola gamma-globulin forty-eight hours after vaccination, and accordingly these 15 children each received 5 ml All 42 primary contacts among the staff had been vaccinated at some previous time, but in 9 there was no satisfactory proof of recent *successful* vaccination, and each was therefore given 10 ml of hyperimmune gamma-globulin Our findings agree with the observation of Kempe et al (1956) that administration of hyperimmune gamma-globulin (twenty-four hours after vaccination in their series) does not interfere with the course of vaccination, for all 24 of our vaccinations were successful Vaccination of the remaining hospital patients and staff (about 1000 persons) was started on June 29, and continued throughout the early part of the following week, revaccinations being done where necessary

The hospital was closed for admissions and discharges on Friday morning (June 29) and visiting was restricted to those seriously ill During the weekend a zone of isolation was set up (on the " hospital within a hospital " principle) using one previously empty ward, which was made into living quarters, and the two wards where case 5 had been nursed This area was roped off, and all 26 primary contacts among the resident staff of the hospital were isolated within it Entrance was restricted to the infectious-disease physicians, the senior administrative nurses, physiotherapists, and engineers Protective clothing was worn (cap, mask, gown, and boots) Food was supplied in destructible containers and all combustible material was removed to the incinerator in bins on a trolley reserved for the purpose

On July 1 a further ward was prepared to receive staff with vaccination reactions and doubtful illnesses requiring isolation and investigation This proved a valuable adjunct, and during the fourteen days it remained open 8 patients were admitted

St Ann's is a general hospital of 520 beds, of which 120 form an infectious-diseases unit There is normally considerable interchange of staff both between this unit and other departments and between the hospital and the other hospitals in the group By re-allocation of duties it was readily possible to avoid or reduce such interchange to the minimum, but the situation within St Ann's Hospital of the central laundry for the whole group gave rise to much concern It was found that no articles used by case 5 had been sent for laundering, and it was therefore decided to maintain the existing laundry services, save that the zone set aside for smallpox contacts would be provided with a washing-machine for each ward

No material therefore left the smallpox zone, except that destined for the incinerator

The closure of the group laundry would have caused considerable disruption in the work of all the contributing hospitals—so much so that the group laundry manager (Mr C H Adams) subsequently followed up the matter elsewhere, with the cooperation of one of us (C G N), and we understand that military mobile laundry units of varying capacities can be hired to meet such an emergency

It seems that the precautions were adequate, for there was no secondary case in the hospital or within the group, and with the uneventful effluxion of the sixteen days' surveillance it was possible to determine all isolation measures on July 15

Public-health Action

Reporting of Outbreak

During the afternoon of the first day, an official telegram was sent to the Ministry of Health confirming the earlier telephone message, the county medical officer was notified, the senior administrative medical officer of the North East Metropolitan Regional Hospital Board was informed of the position, and a circular letter (thereafter issued daily) stating the situation was sent to all general medical practitioners in the borough and to medical officers of health in adjoining local authorities The chief medical officer of the Ministry of Health notified all medical officers of health in the country and port medical officers of the progress of the outbreak by circular letters issued on June 28, July 1, and finally on July 5

Contacts of Case 5 before Admission to Hospital

Case 5 had been attending school until Friday, June 21 The school was visited before closure for the weekend, and duplicate registers and names and addresses of staff were obtained for purposes of offering vaccination or revaccination A list of recent visitors to the patient's home was prepared, including relatives, friends, neighbours, and tradesmen A list of patients since conveyed in the same ambulance was obtained from the local depot Arrangements were made with the Central Public Health Laboratory, Colindale, for the supply of 2000 capillary tubes of calf lymph for immediate vaccination or revaccination of primary contacts and the staff of the health department

Public Relations

On Saturday, June 29, a joint statement was issued to the Press by the hospital and public-health authorities

" In view of the suspected case of smallpox transferred from St Ann's General Hospital on the 28th June, the hospital has ceased to admit or discharge cases Members of the staff who were in direct contact with the patient have been confined within the hospital or if non-resident asked to remain within their own homes The remainder of the staff of the hospital will continue to work in the usual way and are not confined to the hospital All contacts of the suspected case will have been vaccinated during the week-end The clinical diagnosis of smallpox has been confirmed and a relative of the patient has been admitted to a smallpox hospital as a suspected case There is *no* indication for mass vaccination of the general public All those who might receive immediate benefit from vaccination are being visited "

Vaccination within the Borough

A sustained effort followed on Saturday afternoon and Sunday to secure the vaccination of all known contacts in their own homes For this purpose the deputy medical officer of health organised three parties comprising doctor, health visitor, and public-health inspector, to carry out house-to-house vaccination of all contacts Concurrently the deputy area medical officer and area chief clerk opened an emergency vaccination centre at Chestnuts, St Ann's Road, which was continuously staffed over the weekend and for as long as necessary thereafter

Hyperimmune Gamma-globulin

Since doubts were felt about the effectiveness of vaccination so late after contact with the primary case, it was decided to reinforce vaccination with anti-variola gamma-globulin Application was at once made to the Ministry of Health, and half the available stock was released This amount was divided equally between the hospital and public-health departments A dose of 10 ml (1000 mg) for an adult and 5 ml (500 mg) for a child was given to the previously unprotected primary contacts In practice it was found that much patience was needed in preparing the injection The protein proved extremely difficult to get into solution or suspension, and each dose took about ten to fifteen minutes to prepare

Origin of the Infection

In midsummer, in a patient with no known history of recent arrival from, or links with, those parts of the world in which smallpox is endemic, a report of smallpox must immediately arouse two considerations in the minds of those in the central government department concerned with smallpox—that there has been a misdiagnosis (for smallpox in this country is nearly always imported during our winter), or that if the diagnosis proves correct, the disease must have been present in the country, unsuspected, for some little time, and that evidence of this can be found if search is made in the right quarter

In the incident now related examination of case 5 had left no doubt as to the diagnosis No case of smallpox had been notified for some three years, and there had been no recent suspicion of the disease. It was quickly established that there was no link or association between cases 4 and 5 and any foreign country Few could have led a more circumscribed existence than the widowed grandmother, and the boy's (case 5) small world did not extend outside his part of the borough By inference, therefore, it seemed wellnigh certain that a study of recent and not-so-recent death certificates would provide a lead to the source of infection The complete absence of any reported cases of smallpox elsewhere in the country suggested either that the earlier missed case (or cases) must have been modified clinically and have arisen in a patient who was himself vaccinated and belonged to a small well-vaccinated group, or that in this earlier case the patient must have died before his disease had reached the infectious stage The search was therefore at once narrowed to a retrospective inquiry for someone who had died in the early stages of hæmorrhagic smallpox, and the presumption was that the cause of death most likely to have been assigned would be leukæmia Accordingly, at the suggestion of one of us (C G N) a scrutiny was made of all death returns for the past four months, and 4 deaths during that time seemed worthy of investigation, the stated cause of death in all cases including the term "leukæmia" Further inquiries readily disposed of any possible suspicion in the first 3 cases, late residents of Tottenham, but in the case of the fourth (case 3), a licensee lately of the adjoining borough of Islington, an interview with the widow revealed that she and her late husband had visited his brother (case 1) in Wembley, who, with his daughter (case 2, aged 8) had been suffering from "chickenpox" Thirteen days later case 3 became very ill and was admitted late at night to St Ann's General Hospital

This patient had had an acute febrile illness with hæmaturia, massive purpura, and an enlarged liver and spleen, from which he died four hours after admission The leucocyte-count was 28,000 per c mm, 48% of which were primitive cells of the polymorph series *Hæmophilus influenzæ* and pneumococci were recovered in large numbers from a blood-culture As the cause of death was uncertain, the coroner was notified and the body removed to the Prince of Wales's General Hospital for necropsy The purpuric condition, with a leukæmoid blood film, suggested a diagnosis of acute leukæmia, but in retrospect he must be regarded as a case of hæmorrhagic smallpox

Necropsy specimens were sent to the pathology laboratory, where it may be assumed that the cleaner (case 4) became infected The brother-in-law (case 1) of Wembley, a well-vaccinated subject, had returned to this country by air from Lagos, Nigeria, on March 29, and on April 11 had developed a mild illness diagnosed at the time as chickenpox His daughter (case 2), aged 8, vaccinated in infancy, became ill on April 25 also with a mild attack of "chickenpox", but was said to have had a previous attack of chickenpox In retrospect both father and daughter probably had smallpox, and were the source of infection of case 3

Progress of Outbreak in the Borough

Throughout Sunday, June 30, the immediate focus of attention was on the primary contacts Systematically the lists were worked through and gamma-globulin and vaccination, or revaccination alone, was given to the members of the public at greater risk—there were no refusals

A girl, aged 11, not a contact of case 5, was sent on suspicion to Long Reach Hospital, but later proved to have chickenpox An aunt of case 6, who had been vaccinated in infancy and had nursed case 4 (her mother), became unwell and the following day was admitted to Long Reach Hospital, smallpox was later confirmed In due course she made a slow but uneventful recovery The engineering firm where case 6 worked was visited and the staff were advised to accept vaccination Other primary contacts of special mention, living in the neighbourhood, included a married couple and their daughter, the wife of a U S A F airman, who was expecting her first baby at the time She was given gamma-globulin intramuscularly Later in the week she was admitted to an isolation cubicle at the American Hospital, Ruislip, for a normal delivery

The public-health inspectors meanwhile continued to obtain names and addresses of groups of persons at special risk (e g, laundry workers who might have handled contaminated linen from families involved), and directed them to the emergency vaccination centre Gradually the public at large pressed in ever-increasing numbers for vaccination These were diverted to their own general medical practitioners, who obtained supplies of calf lymph held at the Town Hall In the meantime vaccination of children at the school attended by case 5 proceeded well, and was undertaken by the mobile teams of doctors and health visitors The classroom of the patient, and the rooms at the houses where his and other cases of smallpox arose, had been sealed and disinfected Vaccination or revaccination of the ambulance workers at the Edmonton depot was arranged by the medical officer of health of Edmonton

On Tuesday and Wednesday, July 2 and 3, routine home visiting of primary contacts was continued, and many cases needed daily observation, including hospital out-residents and special cases referred by doctors in the district and health visitors—many of these were reactions to vaccination This surveillance continued for sixteen days

Notification of Chickenpox

Because of the close contact with local doctors, who agreed to report all cases of chickenpox, it seemed unnecessary in the early stages to seek action under Section 147 of the Public Health Act, 1936

General Liaison

Under the direction of the chief clerk, rapid compilation of records and distribution of information became the first task of the public-health officers

Other work was put aside except for matters of absolute urgency, and the whole staff concentrated on control of the outbreak This called for sustained work until late at night throughout the first weekend and following week Bulletins to general practitioners and adjoining medical officers of health were sent out daily Lists of contacts, which arrived from St Ann's Hospital and other sources, were classified according to the districts where they lived The medical officers of health of the districts concerned were first telephoned and the information was confirmed the same day by letter For those living within the borough, contact sheets were made out and passed to the district public-health inspectors who undertook surveillance for sixteen days

Besides the information which had to be telephoned out, there were continuous incoming telephone messages and inquiries As a result, despite six telephone extensions in the department there was often an acute shortage of telephone facilities It was also necessary to arrange for the switchboard operators to stay on duty to deal with calls which continued throughout the evenings

National Insurance Benefits

None of the smallpox patients was a contributor for National Insurance benefits, but some primary contacts were able to claim upon the certificate of the medical officer of health

A special emergency procedure, laid down in a Ministry of Pensions and National Insurance memorandum for dealing with claims arising from an outbreak of smallpox, relieves the local national insurance office of any direct contact with the claimants The effect of this was that the public-health department was called on to act as agent for all the claimants It was thus necessary to arrange for the contacts to complete various benefit-claim and authorisation forms, which were retained in the department, and from these to complete weekly certified summaries, which were forwarded to the Ministry of Pensions and National Insurance A lump sum covering the benefits accruing was paid weekly to an officer in the public-health department, who was responsible for its distribution to the claimants

Compensation for Loss of Earnings

Section 51 of the Tottenham Corporation Act, 1952, enabled the local authority to compensate primary contacts for loss of earnings resulting from their exclusion from work The Corporation agreed that compensation should be paid to the extent of making up the difference between the earnings lost and the national insurance benefits received Fortunately the early restriction of the outbreak so limited the number of primary contacts that expenditure on this account did not exceed £100

Supplies of Goods to Households in Isolation

A particular difficulty was that whole households had become primary contacts and were subjected to isolation within their homes This meant there was nobody available to do essential shopping, and in one or two cases the families had no ready money to pay for the goods needed A health visitor was, therefore, asked to visit these families daily and to do any necessary shopping on their behalf Recognition is due to the local tradesmen for their ready cooperation in providing goods on credit pending settlement of the families' claims for National Insurance benefit

Distribution of Calf Lymph

Lymph was made available to doctors at the Town Hall The demand grew rapidly after the first weekend, and altogether 11,500 units were obtained for use by family doctors and at the public vaccination centre 4291 units were issued to medical practitioners and the remainder used by the local authority staff A certain amount of wastage resulted from the use of lymph supplied in multiple units of 10, 25, and 50

Summary

An outbreak of smallpox in Tottenham in 1957 is described

The disease probably entered the country when a man incubating it returned from Lagos 6 probable or confirmed cases were traced, 4 patients, who had been vaccinated, survived, and 2, who had not been vaccinated, died

Anti-variola gamma-globulin was used to give additional protection to the previously unvaccinated primary contacts No secondary case arose within this group, and it seems that this may have in part been due to the protection afforded by the gamma-globulin

We wish to express our appreciation of the part played by all public-health and hospital staff, and particularly to thank Dr J Epsom and Dr J M Medlock

No Smallpox in Lincolnshire

Our report last week of a confirmed case of smallpox at Scunthorpe was unfortunately incorrect A clinical diagnosis of smallpox was made in a 30-year-old Arab and he was admitted to Laceby Hospital Laboratory tests were negative, however, and further inquiries disclosed that the man had been in close contact with children suffering from chickenpox

Scotland in 1957

According to preliminary figures[1] in Scotland the birth-rate last year was 19 0 per 1000 population, compared with 18 5 per 1000 in 1956 The stillbirth-rate—24 per 1000 live and still births—was the same as in 1956 The death-rate was 11 9 per 1000, which is 0 1 below the rate for 1956 The maternal-mortality rate (as in 1956) was 0 5 per 1000 live and still births The infant-mortality rate (as in 1956) was 29 per 1000 live births, and the neonatal death-rate was 20 per 1000, which was 1 above the rate for 1956 The death-rate from tuberculosis (all forms) was 14 per 100,000—9 below the five-year average

Conferences

STRESS DISORDERS

A CONFERENCE organised by the Society for Psychosomatic Research was held in London on May 2–4.

Relation of Stress to Three Groups of Disorders

ESSENTIAL HYPERTENSION

Dr JOHN HAMBLING (Canterbury) described the correlation observed in the labile hypertensive between fluctuations of diastolic blood-pressure and discussion of emotionally charged topics. Suppressed rage and resentment were the most potent diastolic pressor factors. To verbalise or act out these feelings could produce a dramatic fall in pressure. The potential hypertensive usually had at least one parent who was dominating or driving, and he tended to see his life situation in terms of dominance-submission, being ultrasensitive to any authoritarian element.

ITCHING SKIN DISORDERS

Dr BRIAN RUSSELL outlined the neurophysiology and biochemistry of normal and pathological itching. It might ultimately be found that emotionally activated itching had a biochemical mechanism, but this was still unknown. Itching sensations were conveyed by the non-medullated C sensory nerve-fibres and were a form of weak protopathic pain. A stimulus of greater intensity eliminated the itching and replaced it by burning pain, often more tolerable. This itch→burning pain→itch sequence might explain the maintenance by scratching of some dermatoses. It was often difficult to establish the temporal link between "stress" and itching skin disorders without prolonged observation. Dr Russell drew attention to the psychological significance of the terms associated with itching and irritating skin conditions. In his experience itching skin disorders were more often associated with aggressive than with libidinous impulses. Pruritus might occur when a person feared to give expression to repressed or guilt-laden drives.

GASTROINTESTINAL DISORDERS

Dr DESMOND O'NEILL prefaced his remarks with the reminder that disease should be considered in terms of reaction patterns rather than of systems, a new taxonomy was needed, and what Dr Michael Balint called "the pathology of the whole person" had still to be written. The gastrointestinal system reacted to stress in many different ways. Overeating, leading to obesity, was the reaction of some patients to feelings of depression and discontent. Under-eating might alternate with this, or might progress to anorexia nervosa because of guilt about eating. Recurrent vomiting in children was another familiar reaction. In his experience duodenal ulcer was a stress disorder, gastric ulcer not always so. Another syndrome he called "abdominal discontent": the patient felt "fed-up," and complained of heartburn, flatulence, and discomfort, and had sexual difficulties. Most recurrent abdominal pain of which the cause was known could be related to stress. Diarrhœa, constipation, and ulcerative colitis were other disorders of the gut in which the relation to stress was well recognised.

Dr PHILIP HOPKINS said that, in his general practice, of 259 patients with stress disorder 45 had gastrointestinal symptoms. These had responded to simple psychotherapy with improvement, maintained over five years' observation.

Dr NICOLAS MALLESON said that of 500 university students to whom he had given a questionary 150 had reported some disorder of the gut. Stress disorder seemed to show itself more commonly in this system than in any other. He thought this might be because the human stomach, as was suitable to a ground ape, secreted gastric juices all day long. We were built for a casual omnivorous diet, but in modern life we ate like carnivores—alternately gorging and fasting.

Experimental Stress

STRESS IN AVIATION

Group-Captain V. H TOMPKINS (Portsmouth) said that the effect of stress on the airman had been the subject of discussion since the earliest days of flying. As Dr Denis Williams had pointed out, the stresses to which the nervous system of the airman had to become adapted were threefold: the way of life, the job, and the physical conditions of the job (speed, radial acceleration, oxygenation, cold, &c.). It had been found in practice that in these physical conditions there was no specific stress factor comparable in its effects to the psychological factor of fear. Fear was considered responsible in 99.6% of a series of 2200 flying crew who broke down with neuroses. Somatic reactive stress symptoms were usually mild or transient in airmen, who were highly selected. He had the impression that men with mild obsessional traits were more apt to show such symptoms.

EXPERIMENTAL STRESS IN MAN

Dr D RUSSELL DAVIS (Cambridge) discussed the problems encountered by the psychologist attempting to study this subject. Pavlov's dogs, posed an insoluble problem, would develop "experimental neurosis", but the man had a wider range of solutions, his interest was less easily engaged, and he readily "withdrew." Methods using non-specific stimuli such as electric shocks or loud noises yielded little of importance. He had overcome these difficulties in some war-time studies, subjecting pilots to tests of their newly acquired skills. He paid tribute to the work of Kurt Lewin and Zeigarnik. Laboratory methods, however, remained unsatisfactory for the study of sustained stress: its effects were better observed in natural experiments and by clinical methods.

ANIMAL OBSERVATION

Dr R A HINDE (Cambridge) spoke of some studies of the behaviour of animals in nature under stress. Short-term autonomic responses to stress—for example, when two conflicting tendencies were present—might result in a compromise form of behaviour or in a "displacement activity." Many "displacement activities" were now thought to depend on autonomic response to one or other conflicting tendency. He also discussed the theories about the population cycles of certain wild animals, and why after a peak period the population may fall rapidly or "crash". Some workers had described a syndrome marked by liver atrophy and hypoglycæmia in animals that died during the crash period. Selye had pointed out that this "shock disease" resembled a disease of adaptation. This agreed with the finding of a direct relation between adrenal weight and population density in mice in the laboratory.

PHYSIOLOGY OF STRESS RESPONSES

Dr W J H BUTTERFIELD presented the results of his studies of volunteers receiving oral hydrocortisone and of 25 burned patients. Most of the metabolic changes caused by burns could be mimicked by hydrocortisone The size of the metabolic response was roughly proportional to the stress, measured by the percentage of the body burned The liver's failure to metabolise adrenal steroids might play an important role in metabolic changes after burning A further effect of this was the development in some burned patients of diabetes of Cushing-disease type, this might later become insulin-dependent

Stress and Occupation

STRESS DISORDER IN SOCIETY

Dr F M **MARTIN** (Edinburgh) said that epidemiology, had so far contributed little to the study of stress disorder This was because the two prerequisites of accurate counting and significant analysis of data were so rarely fulfilled There was need for the sociological as well as the clinical approach in gathering and evaluating data When rapid changes were in progress in a community the sociologist would focus attention on the stresses this might cause In more stable societies he would look for dysfunctions in the organisation of society and the effect on the individual of his quest for culturally sanctioned goals There was a danger of circular reasoning He did not think the concept of " the stress and strain of Western civilisation " very helpful Hypertension fitted in with this, but duodenal ulcer was common not only in the American Negro but in natives of Nigeria and of South India He thought that the factor of social cohesion merited attention, this had been shown to be significant in the epidemiology of suicide and schizophrenia In this way the social scientist could hope to throw light on stress disorder

STRESS IN INDUSTRY

Dr J J **O'DWYER** felt that industry and work conditions were often blamed for stress caused by family or social maladjustments The social contacts in industry were important, and promotion often caused stress because it made even a charge-hand feel somewhat isolated In managerial staff it might involve the individual and his family being uprooted to move to where the higher job was The industrial medical officer and the general practitioner each knew too little of the other's view of the worker-patient

THE UNIVERSITY STUDENT

Dr **MALLESON** said that about 70% of the students of University College, London, consulted the physicians of the student health service during their three-year course of studies They usually came with some physical symptom, mostly as a face-saving excuse for seeing the doctor for troubles which they themselves attributed to " nerves " The stress affecting the average student fell into two main categories adolescence (sex problems, leaving home, self-management, " growing-up ", &c), and studying for a degree Figures for 1950 and 1951 showed that the more severely neurotic student failed his examinations about twice as commonly as the average, but the slightly neurotic had a lower-than-average rate of failure For the student, as for civilised man, it might be a choice between stress and stagnation

The Person in his Family Setting

THE FAMILY DOCTOR

Dr H N **LEVITT** said that, as a general practitioner, he would agree with Dr Stephen Taylor's estimate that at least a third of general-practice cases were psychiatric The bulk of dyspepsia he himself saw was non-organic The family doctor could often see the effects of the pressure of family, home, neighbours, work, and community, like concentric rings in a magnetic field, surrounding and influencing the patient Sometimes, to break the circuit, removal of the patient to hospital or nursing-home was essential

PERSONALITY DEVELOPMENT

Dr **JOSEPH SANDLER** described the case of a married woman, aged 35, treated by psychoanalysis for vaginismus and phobic symptoms It had become clear in the analysis that the patient had unconsciously sought a stressful condition as a means of gratifying masochistic needs and of averting worse evils

STRESS IN CHILDHOOD

Dr **JAMES ANTHONY** said that in considering stress disorders in children it was difficult to distinguish correlation from causality In one series of 100 children with bowel-training difficulties there was found to be strong correlation between the type of training and later behaviour Strictness and insistence on early sphincter control by the mother was found to result in the child's encopresis or strong aversion to fæces, and undue laxity in training to be connected with soiling Sleep disorders were also associated with stress The child with eidetic imagery was more likely to have nightmares, while the child of haptic, kinæsthetic make-up reacted by sleep-walking

Special Articles

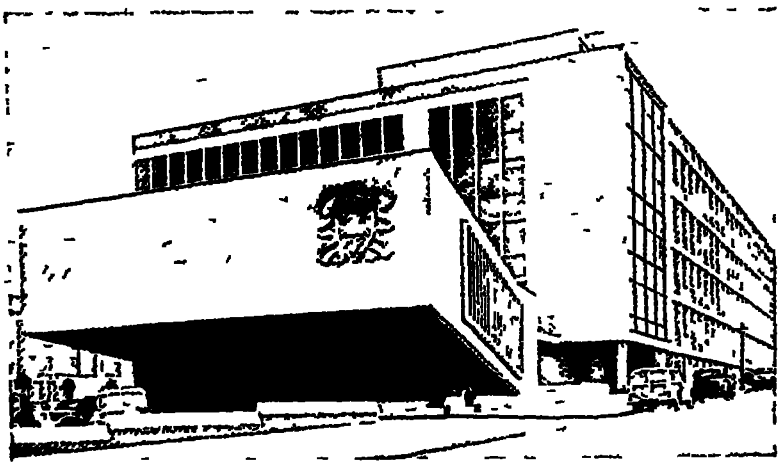
THE NEW LIVERPOOL MEDICAL SCHOOL

THE growth of all departments and the creation of new ones has meant that the medical school at Liverpool (like many others) has been spread around the precincts of university and hospital—in a converted house, a former nurses' home, and part of the city laboratories At last many departments—of pathology, bacteriology, medicine, pharmacology, and obstetrics and gynæcology, with the subdepartment of radiodiagnosis—have been gathered into a new building in Ashton Street

The department of medicine has well-equipped laboratories (provided through the generosity of the family of the late Sir Montague Burton) where electroencephalography and hereditary factors in disease are among the subjects investigated In the department of pharmacology and general therapeutics the studies include the action of drugs on the nervous system, myasthenia gravis, and the thymus In the department of pathology, formerly housed in the Thompson-Yates Laboratories opened by Lord Lister sixty years ago, work is in progress on endocrine aspects of cancer, and in the department of obstetrics and gynæcology cancer in women, toxæmia, and sterility are being studied The work in the department of bacteriology includes investigations on the viruses of smallpox and poliomyelitis and on tissue cultures Each department is housed on one floor, except that the department of pathology occupies most of two floors

Besides these departments the new building contains three lecture theatres and class laboratories for the 506 undergraduate and 177 postgraduate students, as well as the dean's offices, a staff common-room, and a committee-room

Designed by Mr A G Bullen, F R I B A, the building has a flexible plan, for the floor-space on each storey is unbroken, rooms of any size can be made by internal partitions based on mullions at five-foot intervals along the perimeter The frame is of reinforced concrete, with prestressed concrete beams The facing is also of concrete, except for Portland stone on the Pembroke Place elevation (illustrated here), where the principal lecture theatre projects from the main building in a striking manner The whole building is centrally heated and air-conditioned, with provision for removing noxious gases (e g, formaldehyde) and preventing the spread of infection It is hoped to link the present building with a further block fronting Elizabeth Street the completed medical school will then house all departments of the faculty



The new building was officially opened on Wednesday, May 7, by H M Queen Elizabeth the Queen Mother, after an address by Lord Cohen of Birkenhead, professor of medicine in the university, who sketched the development of the Liverpool School of Medicine from its foundation in 1834 He said that the pride of a school "lies not simply in the beauty and dignity of its architecture, but in the contribution which those who labour within its walls make to 'the advancement of learning and the ennoblement of life'" He referred to the work of three great Liverpool contemporaries—Sir Ronald Ross, Sir Robert Jones, and Sir Charles Sherrington, all born a hundred years ago

Later, at a congregation in the Philharmonic Hall, the honorary degree of LL D was conferred on Her Majesty, and on Lord Adrian, Sir David Campbell, Sir Allen Daley, and Sir John Hobhouse Speaking on their behalf, Her Majesty paid tribute to the part Liverpool had played in advancing medicine, in Liverpool, she said, "visitors are conscious of a pulse like a hammer and a vigour which nothing can daunt"

Parliament

An Institute of Criminology

ON the adjournment on May 7 Mr MONTGOMERY HYDE pointed out that, unlike other European countries and the United States, we had in this country no institute of criminology though it was generally agreed that crime and its methods of prevention and treatment deserved careful and detailed study No university in the United Kingdom had a chair of criminology, though Cambridge had a department of criminal science with a director at its head Otherwise the university teaching of criminology in this country usually formed part of the syllabus for the study of sociology, psychology, or other social sciences At present, readerships in criminology existed only in Oxford and London, the latter tenable at the London School of Economics and Political Science Some of the provincial universities provided courses in the subject or some branch of it, but teaching was mostly confined to a few odd lectures, though at the Queen's University, Belfast, special attention was paid in the department of psychology to juvenile delinquency No degrees or diplomas in criminology were available here A British institute of criminology could coordinate the teaching and research If it were to concentrate at first on postgraduate work, its activities might stimulate the teaching of criminology to a graduate level in the universities Then, if it set the high standards which were to be expected, a qualification in criminology might well become desirable or even obligatory for those concerned with the administration of justice Later non-diploma courses conducted by the institute for justices, police, probation, and prison officers could prove of value, not least as a common meeting ground for discussion

Sir GEORGE BENSON paid tribute to the work of the new Home Office research section But its research was intensive and practical, and it was no substitute for an institute which would be a general educational force in the community We allowed our courts, our magistrates, and the whole administration of the penal system of the country to rest on pure guesswork and tradition Nowhere at present could the court and the penal machine look for guidance and information An institute of criminology was a vital need

Mr DAVID RENTON, the joint Under-Secretary of State for the Home Department, said that the Home Secretary had been giving much attention to the suggestion made to him by the Howard League that the time had come to encourage the establishment of an institute of criminology in this country He was convinced that the vigorous pursuit of research into the causes of crime and the treatment of offenders was urgent especially at a time when crime was increasing and none could say what were the fundamental causes of that increase Mr Renton himself thought that such an institute would have two ends—to train, preferably at postgraduate level, those who would carry out research and teach others in future, and to provide teaching facilities for those who were concerned in their daily work or in voluntary service with the prevention of crime, the administration of justice, or the treatment of offenders—for example, magistrates, probation officers, members of the police force and of the prison service In addition, such teaching might help to form a better-instructed public opinion

Much had been done in recent years to increase research and develop teaching in this field, and the Home Office had done its best to give such help and encouragement as its resources would allow Research was being planned or was being carried out on the nature of group relations in prisons, the changes brought about as a result of the "Norwich" experiment, the sentencing practice of the courts, the social consequences to offenders of being convicted and sentenced, crimes of violence in the Metropolis, and the development of prediction studies He agreed that Great Britain was today almost alone in having no institute for the study and teaching of criminology, no chair in criminology at any university, and no separate university qualification in this subject It might well be that a stage had been reached where the establishment of such an institute within one of our universities would be of great value, in order to give a new impulse to studies in this field, to set high standards in a subject whose academic status had not yet been fully recognised, and also to meet a growing demand for teaching in this subject The Home Secretary accepted that view and he had undertaken informal consultations with university authorities Those consultations were still in progress, and were necessarily still confidential, but he hoped that they would lead to useful results

Professional Income-tax Allowances

In moving the second reading of the Finance Bill on May 12 Mr J E S Simon, financial secretary to the Treasury, said that clause 14 embodied a proposal which would receive much support Relief would be allowed for annual subscriptions to professional and learned societies with activities related to the employee's work Subscriptions to Associations such as the medical defence Associations and the statutory registration fees, set out in the fifth schedule, paid by such people as architects and dentists as a condition of being allowed to practise, would also be allowed The Commissioners of Inland Revenue would approve societies for the purpose of allowance of subscriptions by reference to the criteria which were laid down in the body of the clause, and subject, of course, to the usual rights of appeal The general test would be whether a society's activities were wholly or mainly of a professional or learned character Where such a body also had significant activities of a different kind, such as the prosecution of salary claims, the clause provided for the deduction of a fairly apportioned part of the subscription

Mr Eric Fletcher here asked whether it was intended to deal with subscriptions paid to learned societies by way of covenant? Until recently these had the advantage of enabling learned societies to recover the tax paid A recent decision in the Court of Appeal had brought about a different result Was clause 14 intended to restore the position in that respect? Mr Simon replied that clause 14 did not deal specifically with that matter, although, where the institution otherwise qualified, money paid under the covenant would rank as a deduction

QUESTION TIME

Poliomyelitis Vaccine

Mrs Barbara Castle asked the Minister of Health what target he had set for the production of anti-poliomyelitis vaccine by Messrs Glaxo and Burroughs Wellcome, respectively —Mr. Derek Walker-Smith replied It continues to be the Government's intention that, as soon as supplies are sufficient, only the British type of vaccine should be used in the vaccination scheme The manufacturers are aware of this, and the issue of individual invitations to produce vaccine does not arise Nor is there any question of the Government setting a production target for individual firms

Mr Cledwyn Hughes Is the Minister aware that in many cases the British vaccine is being given for the first vaccination and a foreign vaccine for the second? Would he say whether that is approved by his Ministry's experts?—Mr Walker-Smith It is quite all right, on medical grounds, to vary the type of vaccine between the two injections

Mr Richard Fort asked the Minister when the substantial new supplies of Salk vaccine would become available for use in this country —Mr Walker-Smith replied 2 million doses of Salk vaccine which have passed their tests and been licensed for issue in America are due to arrive on May 13, and they will be distributed immediately to local health authorities Another $1^1/_2$ million doses of this vaccine are expected next week In addition, a batch of $^1/_2$ million doses of British-tested Salk vaccine is now being distributed, and further supplies are expected as tests are completed

London Teaching Hospitals

Mr Marcus Lipton asked the Minister what plans he was now considering to reduce or change the number of London teaching hospitals —Mr Walker-Smith replied None, Sir

Mr Lipton Has the Minister seen the reports stating that he is considering closing three London hospitals—Charing Cross, St George's, and Westminster? Is there any truth at all in those reports?—Mr Walker-Smith I did see a report in a usually well-informed newspaper, but, in fact, I am not considering that course There are certain proposals in mind with reference to Charing Cross and the Royal Free Hospital, but there is no question of amalgamation

In England Now

A Running Commentary by Peripatetic Correspondents

Reactions to the bus strike make an interesting medico-social study Observations outside a large South London hospital showed that over the first four days the passenger/car ratio increased from 1 7 to 3 2, a difference held to be significant at the 1% level and the increase appearing to be linear against the log time Unless the curve starts to flatten out there will be people sitting on the roof At busy times the cars queue up at bus stops waiting to offer lifts Further effects are less easy to measure directly, but one may readily conjecture a few the increasing networks of little friendships for a start " Oh do you always come this way, that *would* be kind ", then " Tomorrow morning as usual then ", and finally " Do bring the family round this Sunday " The increase of togetherness and raising of morale, not to mention chance romantic encounters, cannot but have a good effect on the mental welfare of the community as a whole, and hospital admissions should soon reflect this if Messrs Macleod and Cousins can be persuaded to remain adamant

Apart from the weather, we haven't had a direct stirring challenge for a long time and it will do us good My wife's evening class, for example, was on the first night of the strike and is never very well attended I said surely no-one would turn up, so she might as well get on with the supper, but it didn't work I had to drive her there and there was the biggest turnout of the year Motivational research should get going here did the class overcompensate to the difficulty as one man, or rather one woman? Or were they bored after a long day at home? Or was there some contaminating factor? A fruitful field awaits the enterprising worker these situations must be exploited by those pursuing PH D s

The effect on the busmen may be less happy, though in course of time the differential between drivers and conductors of peptic ulcer and coronary thrombosis (Morris 195-something) should iron out A survey of how strikers spend their time would be worth while Do conductors wander nostalgically up and down stairs? A number of them, of course, have their duties to attend, and face the same difficulties of getting to work as the rest of us A friend of mine offered a lift to a stranded bloke yesterday and only at the end of 15 miles did he discover his passenger was a strike picket going to his station

There are other smaller groups to be considered of course A friend in the bicycle and scooter trade is in danger of passing into an acute hypomanic state give the strike another fortnight, he says, and he will retire Trade-union officials, one fears, may be liable to anxiety attacks, and then of course there's the Government Apart from fluctuations in blood-pressure we would rather not commit ourselves on this delicate subject perhaps a medical M P could be persuaded to fill this gap in our scientific knowledge

* * *

It has been a good lambing time and the countryside is full of the attractive youngsters, playful, thoughtless, and impulsive, just like our own children I met three ewes and their lambs yesterday as I entered the enclosed road when coming off the fell from seeing Charlie's children The ewe on the offside had her lamb with her, so I steered quietly between the mothers, but one of the lambs on the nearside evidently belonged to her, and at the very last moment he dashed across the road and disappeared from my view behind my nearside wing Sixpennyworth of rubber left my tyres in a cloud of smoke, and I didn't feel a wheel go over him, nor did I feel him hit me, but I got out with a very empty epigastrium, and there, in the road behind, he lay, very still and with his nose bleeding I carried him to the roadside, and after ten minutes or so he was holding up his head, looking for his mother and seeming much better So I left him and went back to lunch, intending to go up and see if he was all right after afternoon surgery

Charlie came down for the children's medicine before I left, so I asked him if he had seen the lamb "Yes," he said, he had seen it It had a dirty nose and he thought it had had an accident, but it was with its mother and quite all right, and I was not to worry about it My wife heard this bit of conversation, and after he had gone she gave me one of those quizzical motherly smiles that she keeps for me when she finds out something that I hope she won't notice "So that was what was the matter at lunchtime," she said "You hardly ate a thing and didn't say a word If a lamb does that to you I hope to goodness you never run over a child" Remembering the empty epigastrium as I got out of the car, I hope to goodness I never do

* * *

I know a hospital where the Royal Arms, in all their splendour of gilt and scarlet, are floodlit above the portico and where an alcove in the entrance hall is occupied by a portrait of a beautiful Queen Consort The corridors are decorated in contemporary colour schemes and adorned with boxes of growing flowers and tanks of tiny coloured fish The wards are divided into four-bed and two-bed cubicles, also in contrasting colours, and with sound-proof ceilings, and the ward kitchens are equipped with stainless steel sinks and cupboards The surgeon's clients are anæsthetised to the sound of music under a painted ceiling Can this be the National Health Service? Of course not It is a well-known military hospital not far from Lambeth Bridge

* * *

The ordering system in our department is complex, with numerous highly coloured forms to be signed in triplicate Just recently it became our duty to sign them, and we were fascinated to find what the department had been running on all these years We even got round to making tentative little inquiries of our formidable senior technician when we found him in a good mood "What," we would ask timidly, "do we *do* with all these assorted grummets?"

After a time we became a little bolder and actually attempted to strike out one or two items, but it made no difference, they always came back on the next order form, and we were given to understand that interference of this sort made the department almost impossible to run Eventually we became almost anæsthetic, and nowadays we sign our name without a moment's thought to "36 only alum pudd steamers, complete with lid"

But the other day our eye was caught by an item reading

1 only tin tray with picture 4s 0d'

We no longer dare to approach our senior technician on matters of this kind, but we sent at once for our new secretary, who is always glad to enlighten us It seems that the Professor's tea tray had become a Disgrace, that a tin tray with a picture on it is cheaper than a tin tray without one, and that the picture would almost certainly prove to be a spaniel, the trade considering spaniels to have maximum sales appeal

Convinced by these telling arguments, we signed without demur, and it was not until the matter came up at the afternoon tea club yesterday that we remembered that the Professor is greatly attached to his fox-terrier A rough canvass of departmental opinion only too clearly supported our fear that the appearance of a spaniel might be regarded as a studied insult It was widely felt that we had been too precipitate, and should have specified a psychologically neutral picture We were forced to speak sharply to one of our demonstrators, and our senior lecturer, who owns a Siamese cat, referred slightingly to dogs in general At this a visiting dog-lover from biochemistry swallowed a cigarette in his agitation, and had to be revived with copious draughts of hot water The meeting broke up in a general huff, and our migraine came on worse than ever

It was therefore with some relief that we welcomed this morning an end to the suspense in the shape of the arrival of the tray itself "We have pleasure," said the accompanying letter suavely, "in supplying to your specification 1 only tin tray with picture, price 4s 0d, and trust that it will meet your requirements adequately"

With trembling fingers we undid the string It was, of course, *The Boyhood of Raleigh*

Letters to the Editor

TOXOID OR A T S?

SIR,—It is perhaps not generally realised that considerable sections of the civil population have received and are receiving active immunisation against tetanus These sections include (*a*) those young men who have completed their National Service, (*b*) the increasing number of young children who are immunised with triple antigen, and (*c*) an appreciable number of older children from independent schools where routine active immunisation is practised

In the event of injury these individuals should be given a booster dose of tetanus toxoid It is unnecessary and indeed undesirable to run the risk of sensitising them to horse serum by administering A T S Members of my Association do their best to instruct actively immunised individuals that they should ask for toxoid in place of A T S if they are the victims of an accident Nevertheless it has been found that this request is all too frequently disregarded particularly in busy casualty departments and A T S is given willy-nilly

I have been instructed by my Council to bring this point to the attention of the profession through your columns We would wish that all individuals who are actively immunised should be clearly instructed that they have received *toxoid* and are to ask for this to be repeated if they sustain an injury On the other hand, we invite casualty officers and others to bear in mind the increasing possibility that the patient has been actively immunised, to ask in every case of injury if this is so and if the answer is in the affirmative to administer toxoid rather than A T S

SYMPTOMS AFTER CHOLECYSTECTOMY

SIR,—As a physician seeing many patients with gallstones, one must agree with Mr Burnett and Mr Shields (May 3) that the use of the term "postcholecystectomy syndrome" is not justified At the same time general physicians themselves see many patients who have had a diseased gallbladder removed without losing many of their symptoms In point of fact the results of this operation are not conspicuously good as far as my general experience goes Despite this it is certainly very proper to recommend removal of gallstones in nearly every case, but the reason for such advice must rest on certain general principles which are not covered by Mr Burnett and Mr Shields The benefits to the patients are long-term not immediate

Gallstones and diseased gallbladders must be removed for three reasons (*a*) to prevent further gallstone colic, (*b*) to forestall a nasty attack of acute cholecystitis, and (*c*) to prevent the remote danger of carcinoma of the gallbladder In these three respects I often feel that the operation is done as much for the benefit of the patient's doctor as for the patients themselves It is as well to point this out to the patient preoperatively so that they are not misled into thinking that passage through the surgical ward and loss of the gallbladder is going to restore them to complete mental and physical health

Exactly what symptoms a diseased gallbladder gives rise to is a matter which very few people can accurately define But when one remembers that in most instances the organ which is removed is not functioning and has failed to function for many years, it becomes quite clear that its simple removal cannot restore function, so the symptoms must continue Gallbladder function is not essential to digestion, but its absence will often be felt after greasy meals

This no doubt is the answer to the problem of the many patients who continue to complain after operation Even though the common bile-duct does distend it cannot take over the concentrating function of the gallbladder or produce a cistern-like flush of concentrated bile at the psychological point in digestion Whether this lack of concentrated bile does in fact give rise to symptoms of diseased gallbladder must be a matter for discussion, but it is certainly present both before and after operation and operation itself does nothing to alter this fact

But beyond this is the very frequent problem of whether what the patient complains of is indeed due to a diseased gallbladder Mr Burnett and Mr Shields have indeed pointed out that it is not unusual to find that postcholecystectomy symptoms have in fact been due to duodenal ulcer or some other intra-abdominal disease But more commonly the symptoms are due to a small hiatus hernia which has not been diagnosed or to simple reflux œsophagitis which has also not been suspected Because of these two conditions, it is my general practice to slim the patients before sending them to have their gallbladder removed, provided of course the patient is not suffering from repeated attacks of gallstone colic This simple process so often removes symptoms previously regarded as due to the gallbladder that unfortunately the patients are often reluctant to have their gallbladders removed

One further explanation of the poor result of cholecystectomy remains—namely, in most cases the sufferers are obese women in late middle life who are often suffering from hypertension, coronary disease, bronchitis, or some other organic disability which continues to give trouble after operation If the organic side is not at fault in these patients, they are emotionally battered and beset by large families, small incomes, and much work They would in any case give rather poor results after any form of surgery

We are at the moment going through a changing pattern in regard to cholecystitis which may make for better results in the future A diagnosis is now being made after the first or second pregnancy and gallstones or gallbladders are being removed in younger women with much better long-term results Operation at an earlier stage in gallbladder disease would therefore give better results and should be our aim But in summary the relatively poor symptomatic result after operation here is due to the fact that most of the symptoms complained of subsequently were really present before the operation was undertaken and could not be expected to be helped by surgery in any case

Liverpool **ROBERT KEMP**

SIR,—I should like to comment on the article by Mr Burnett and Dr Shields

In the summary and in the text they say that they found no evidence of biliary dyskinesia If their case-summaries are complete, I submit that the surgeons who operated on these patients did not look for a dyskinesia The only methods of diagnosing biliary dyskinesia accurately are serial cholecystography,[1] one of the methods of manometry,[2] and chronovolumetric estimation of bile,[3] which can be misleading One can, however, suspect a dyskinesia from the clinical history

All the cases quoted in table II, with the possible exception of cases 13 and 20, could well have a dyskinesia On the necessarily meagre details given in the tables I postulate that cases 7, 8, and 17, in addition to their vesical calculi, had a biliary vesicular stasis, probably due to a biliary hypotonia, which was neither diagnosed nor treated at the first operation The biliary hypotonia was the primary and more important abnormality and the stones the secondary The primary abnormality remained and so did the symptoms Case 10 almost certainly has a hypotonic dyskinesia The patients with duodenal ulcers may have had a hypertonic dyskinesia secondary to the ulcers at the first operation and may have it still

Mr Burnett and Dr Shields say, "We had intended to study patients with 'biliary dyskinesia', but we were unable to find one We conclude that this condition does not arise where cholecystectomy is done for such reasons as in this series" This conclusion, I humbly beg to suggest, is totally unwarranted if the authors took no steps to discover the presence or absence of dyskinesia, and they do not say that they took such steps as are necessary to make this diagnosis The information they give leads me to believe that had the necessary steps been taken a dyskinesia would have been demonstrated in the majority of their cases

USE AND TOXICITY OF SULPHONAMIDES

SIR,—In his letter of April 26, Dr Laurance asked for suggestions from the manufacturers as to a method for ending the confusion caused by the similarity of the names of 'Sulphamezathine' and sulphamerazine This is a situation which has also been causing us some concern, and with the idea of effecting an improvement we recently registered the alternative trade mark 'S-mez' for 'Sulphamezathine' Already we find it welcomed by doctors as distinctive and easier to write Further, and in line with Dr Laurance's final point, we have taken steps to ensure that the official *B P* name, sulphadimidine, is given prominence on all labels and literature for 'Sulphamezathine' and its preparations

SEPARATION OF MOTHER AND CHILD

SIR,—In their letters commenting on mine of March 1, Dr Kräupl Taylor (March 22) and Dr Howells (March 29) raise rather different points Dr Taylor draws attention to certain shortcomings in a recent publication[1] and asks for further particulars these I shall try to provide on my return to England

Our discarding of certain data as unreliable was done on the basis of defined criteria and only when two independent judges were in agreement that one of the criteria had been met (see p 222) In our view it is the quality of the data rather than our handling of them which is most open to criticism My theoretical and practical conclusions naturally rest on a broader basis than these data alone

At many points Dr Howells and I are in agreement The distinction between separation and deprivation is discussed in the opening paragraphs of *Maternal Care and Mental Health*, while much of the second part is concerned with how best to care for children out of their own homes so as to avoid their suffering privation Further, we agree that much mental ill health in children arises from privation suffered by them while living in their own homes Where we seem to differ is in the weight we give to the emotional attachment that commonly exists between a child and his mother (and the rest of the family) and the anxiety and grief which result from the rupture of such relations He seems to suggest that separation without privation is of no consequence Admittedly, as Dr Howells' own work confirms, stays with relatives and friends whom the child already knows and trusts need have no ill effects The acute distress and anxiety which young children experience when placed with strangers, no matter how kind, is well attested however (e g, Heinicke [2]), while the records of children who have been moved from one good foster mother to another show that cumulatively such experiences can have very adverse results

---

[1] Bowlby, J , et al *Brit J med Psych* 1956 29, 211

It is because the removal of a young child from his home to the care of strangers is usually productive of intense anxiety, misery, and anger (often even when the home he leaves is a bad one), and also because it all too frequently leads to further moves, that I believe it should be undertaken with great circumspection Efforts to improve the home, though requiring time, skill, and patience, are in many cases preferable in the long run.

As from Tavistock Clinic,
London

JOHN BOWLBY

IODINE PROPHYLAXIS OF GOITRE

SIR,—In a leading article in your issue of April 12, you advocated the addition of some form of iodine to all the table or kitchen salt sold in the United Kingdom, except that which might be demanded free from such addition "The United States, Switzerland, and New Zealand have been using prophylactic iodine for several decades, and goitre has notably declined in all three countries" May I point out that the iodinisation of salt is not required in the United States and that its general use there, or elsewhere, is scarcely a matter of "several decades" but of only two or three

Of greater significance is the fact that goitre has been diminishing in prevalence and intensity in Switzerland for more than fifty years before iodised salt was introduced into *any* canton.

In opening the First International Goitre Conference, the president stated "les goîtres enormes, difformes, qui frappaient autrefois l'observateur a premiere vue ont presque disparu" [3] He also called attention to the change in the proportion of recruits rejected from military service because of goitre from 10% in 1885 to 2·97% in 1912 and 1·3% in 1924–5 The figures later collected by Schaub [4] showed that the decrease was greater between 1905 and 1910 than in any similar period after the introduction of iodised salt

Similar changes have been reported from England [5 6] and many other places from Rumania to the United States, West Africa, and South America [7–15] In at least one instance, the disorder returned after an absence of about fifty years, to be regarded as a new disease [16]

In 1927, Cornwall and the Isle of Wight were among the districts in which were found the highest proportion of enlarged thyroids among schoolchildren Can it be seriously contended that their diets were more likely to be deficient in iodine than were those of the children of Bedford and Hertford with less than half the proportion of goitres or of Cambridge and Huntingdon with less than a tenth? [17]

The use of iodised salt is not without its possible dangers Many have not observed any ill effects but others have The literature abounds in instances, but I shall quote only from *advocates* of the use of iodised salt

In New Zealand, the number of patients admitted to public hospitals because of exophthalmic goitre during the five years following the introduction of salt containing 1 part of potassium iodide per 20,000, after a longer period with a lower concentration, increased by 7% although the number of those admitted because of other thyroid diseases fell [18]

In Lausanne, the proportion of adenomas of the thyroid encountered in *all* the necropsies increased from 1936–37 to 1946, in all except the lower age-groups, whether the comparison was between either or both sexes at the same age or between groups dying in 1936–37 with similar groups ten years older in 1946 [19] Marine [20] recognised that the introduction of iodised salt had been followed by an increase in the number of cases of hyperthyroidism He regarded this as a temporary phase, to disappear as the number of new goitres falls Perhaps his faith will be justified, but there is no good evidence that this will be the case or, if it should occur, that the use of iodised salt should be considered responsible

It may well be that the change from simple goitre to hyperthyroidism is not due to iodised salt but to unknown factors However, if one may argue *Post hoc, ergo propter hoc* to show that iodised salt has diminished the number of simple goitres, one may suggest that the same may hold for the increase in hyperthyroidism

Would it not be well to make another survey to find out if there has not been in England a great diminution in the prevalence of simple goitre since 1927? Or shall the United Kingdom join other nations in emptying the ocean with a pail when the tide is running out.

of Medicine.

ISIDOR GREENWALD

REGIONAL DISTRIBUTION OF CONSULTANTS

SIR,—The figures for consultants, beds, and population for each regional hospital board (given in your issue of April 26, p 907) make interesting reading I calculated the number of beds and population per consultant and also the number of hospital beds per 1000 population in each region as follows (I have omitted the two smallest regions)

Region	*Beds per consultant*	*Population per consultant*	*Beds per 1000 population*
Newcastle	46	8867	5·2
Leeds	76	13,215	5·7
Sheffield	70	14,842	4·6
N W Metropolitan	42	9386	4·5
N E. Metropolitan	60	9789	6·1
S E. Metropolitan	56	9096	6·1
S W Metropolitan	50	9328	5·3
South Western	64	10,750	5·9
Welsh	68	11,102	5·9
Birmingham	57	11,390	5·0
Manchester	73	13,563	5·4
Liverpool	72	10,862	6·6

The variation is quite staggering, and if the consultant cover for the whole country were brought up to that of the best-staffed regions, I estimate about 1600 new consultants would be needed

Such "backward" areas as Leeds, Sheffield, Manchester, and Liverpool, in particular, need strong reinforcements, and Sheffield in addition is obviously short of beds It would be interesting to know the number of S.H.M.O.s in each region, and if these are known, perhaps you, Sir, would publish them It may well be that the regions poor in consultant cover are using an excess of S.H.M.O.s and, if so, this fact should be considered by the committee reviewing those S.H.M.O.s who claim to be doing consultant work. I rather suspect, however, that the areas with low consultant cover will also be low in numbers of S H M O s

SPERMATOGENIC REPOPULATION OF MOUSE TESTIS AFTER X-IRRADIATION

SIR,—A single 1000r exposure of male C57 black mice shielded above the pelvis resulted in the usual depopulation of the spermatogenic tubules

Three weeks after exposure tubules appear essentially empty except for certain cells lining the basement membrane These have been called Sertoli elements by many observers Closer seriation of the preceding events reveals the following

Acute exposure to 1000r leads to death of all spermatogonia Spermatocytes continue to develop until they meet a block at or near first meiotic anaphase This block has been found to persist in the present material for at least ten days The division block leads to a restitution M1 (first meiotic metaphase) division The resulting diploid cell appears viable Groups of such cells gradually move to the basement membrane, where they take up positions beside the surviving Sertoli nuclei These restituted cells can thoroughly mimic the appearance of Sertoli units With time, and in certain tubular-cross sections, these "restituted M1 survivors" divide mitotically and give rise to a new spermatogonial layer, from which the complete cycle of spermatogenesis is gradually rebuilt

A detailed account involving autoradiography and electron microscopy is being prepared

ADRENALINE CREAM

SIR,—Dr Moss (March 29) will be pleased to hear that not all the clinical trials of adrenaline cream have been so perfunctory as he suggests

In a strictly controlled "double-blind" investigation recently conducted at this and other hospitals, the analgesic effect of adrenaline cream was compared with that of two rubefacient ointments and an inert substance The two rubefacients selected were nonylic acid vanillylamide combined with the β-butoxyethyl ester of nicotinic acid, and a combination of methyl nicotinate, glycol salicylate, histamine dihydrochloride, and capsicum oleoresin These are the active principles contained in two well-known and widely used proprietary ointments

50 patients with degenerative joint disease of the spine were subjected to the trial They were thoroughly questioned, examined, and assessed at fortnightly periods before, during, and after being told to apply each ointment They received no other concomitant therapy

The results of this trial are interesting In only 9 of the patients treated was there any measurable objective improvement following the use of any one of the ointments, and in 3 of these this followed the use of the inert cream Subjective assessment showed that 21 patients preferred the ointment containing the nonylic acid vanillylamide, 11 preferred the methyl nicotinate combination, 4 preferred the adrenaline cream, and 4 the inert cream 10 patients were unable, or unwilling, to express any preference

Although, in fact, these results do not attain any strict level of statistical significance, certain conclusions may be drawn

(1) Objective improvement cannot be expected to follow the use of analgesic ointments

(2) In the conditions treated, the majority of patients experienced greater symptomatic relief from nonylic acid vanillylamide combination This was, in fact, the more effective in producing skin hyperæmia and the more irritant of the rubefacients tested, its application has been shown by Symons [1] to produce significantly higher skin temperatures than other available preparations

(3) There appeared to be little difference between adrenaline cream and the inert cream in relieving symptoms These are obviously the least effective in producing hyperæmia

One cannot, with our present lack of knowledge of skeleto-muscular physiology, attempt to draw conclusions as to the mode of action of these applications, but the impression is that the efficacy of an ointment in relieving symptoms is directly proportional to its local irritant action Why this should be so is not immediately obvious, but I feel that it is significant that several patients, when describing the change of symptoms that resulted from the use of the most potent rubefacient, stated that they "felt that it was doing most good", surely some psychosomatic explanation could be the answer

Orpington Hospital,
Orpington, Kent

P HUME KENDALL

RELEASE BINDINGS ON SKIS

SIR,—Referring to your note on this subject (April 26, p 917), I most strongly endorse the findings given, having used efficient release bindings covering torsion and forward throw for some five seasons I have never suffered anything worse than the slightest joint soreness, and neither have my skis become detached in normal skiing A reasonable mechanical sense to adjust the bindings correctly is necessary

The design of "safeties" is difficult, especially if ski-mountaineering is undertaken, it being imperative to avoid accidents under high alpine conditions I have such faith in "safeties" that I do not insure, taking into account the very high premiums

There is still extreme bias against "safeties" on the Continent among instructors and others, and the novices who need them most use them least, as the figures you quote show I can see no valid reason whatever against the adoption of properly adjusted "safeties"

Beaconsfield, Bucks

NICHOLAS DALTON

VISITING MENTAL HOSPITALS

SIR,—Throughout this country, and indeed the world over, there are people who devote much of their time and some of their money to visiting lonely patients in hospital Yet such visits, by those who are neither relatives or personal friends, are seldom permitted in our mental hospitals, where the need is greatest It is in mental hospitals that so many patients live on year after year—their relatives having died or deserted them—receiving no letters, and having no contact with the outside world Since it requires but little imagination to appreciate their loneliness, it seems to me strange that, whereas a request to visit a general hospital for philanthropic purposes is welcomed, a similar request to visit a mental hospital is likely to be turned down

Though it may be true that comparatively few would care to penetrate the somewhat bleak and grim realities of everyday mental-hospital life, I am nevertheless certain that a substantial number of good people could be found willing to do so Some authorities will say that visits by medically untrained persons are fraught with danger But the risks are largely neutralised by the fact that responsible nurses are always on duty in the wards, and also by imposing the condition that *nothing* whatever (except tobacco, sweets, books, and writing-paper) may be taken into the hospitals by such visitors After all, our visiting chaplains are not medically trained either

---

[1] Symons H F B *Ann phys Med* 1958 2 174

But the advantages of visiting have already been demonstrated in practice as well as in theory I know of a Scottish mental hospital, for example, where the physician-superintendent has arranged with various local Church guilds to " adopt " the more lonely of his patients, and to give them friendship, and even an interest in life Here, once every month, a busload of guildswomen arrive at the hospital, there is chatter and laughter in the corridors, there are picnics, days at the seaside, and even days spent in the comfort of their visitor's own home

All the mentally ill are, at bottom, starving for the want of love, and for outside interest in themselves Since there are people willing to do what they can to help these patients, surely every mental hospital ought to be encouraging—indeed seeking—such help?

Edzell, Angus H G WOODLEY

RETICULOHISTIOCYTOSIS

SIR,—In *The Lancet* in 1955,[1] under the heading A Rare Disease with Features Resembling both Rheumatoid Arthritis and a Lipoid Accumulation, I referred to the case of a man which I first described with Dr W Freudenthal,[2] under the heading Nodular Non-diabetic Cutaneous Xanthomatosis with Hypercholesterolæmia and Atypical Histological Features Dr George Graham gave me frequent opportunities of observing the case of a man under his care with analogous symptoms This man ultimately died and an elaborate account of his case was published[3] under the heading A Case of Hitherto Undescribed Lipoidosis simulating Rheumatoid Arthritis I now believe that Graham's case was of exactly the same nature as that of Parkes Weber and Freudenthal, but complicated by the supervention of a sarcomatous growth and a microbic infection, which caused the patient's death The case of Weber and Freudenthal apparently subsequently recovered with considerable permanent changes in bones and joints[4] I think that " congenital development diseases " are not so very rarely terminated by the supervention of malignant growth, which complicates the diagnosis

London W 1 F PARKES WEBER

"THESE DYING DISEASES"

SIR,—Dr Vickers (March 19) advocates abolition of the venereal-diseases clinic and dispersion of its patients to other hospital departments This, from a dermatologist, is very strange syphilis is still the great imitator, and rashes appear to be the least common sign in early or late syphilis In the Services, venereal diseases and skin diseases were formerly combined, but early in the late war it was found necessary to separate them—particularly on the insistence of the dermatologists

Under Dr Vickers' scheme the following questions would arise

(1) Would a patient be able (as at present in V D clinics) to attend without an appointment and without a doctor's letter?

(2) Who would see the transient patient—e g the long-distance driver, or seaman, who carries a small travelling book (V 15 and V 44 respectively) in which all treatment given and all pathological reports are recorded Could the patients be seen immediately and by whom?

(3) Who would undertake the care of the pregnant syphilitic woman, and which department would investigate false positive Wassermann reactions? Who would be responsible for telling a patient, without confirmation, that she has syphilis—knowing the likely effect on the patient and the family, and the risk of legal action against the doctor?

(4) Who would see the cases of Reiter's syndrome—the ophthalmologist, the genitourinary surgeon, or the general physician?

(5) Which department would deal with neurosyphilitics with cardiac complications?

Investigation of the patient's social background, tracing contacts, and dealing with " case holding " until adequate treatment has been given is not the work of the several departments mentioned by Dr Vickers Moreover the V D patient prefers the confidential approach and constant sympathetic staff found in V D clinics

The success of the anti-V D scheme in Great Britain has depended largely on the coordination which the venereologist has created from the chaos which existed when so many treated venereal diseases And, whereas the returns to the Ministry as at present compiled by the venereologist are at least a good indication of the epidemiological situation of venereal diseases, under Dr Vickers' regime no return would ever be completed

The Royal Hospital, Sheffield, 1 A I MORRISON

CEREBRAL PALSY

SIR,—Although I hardly dare to quarrel with the definition of cerebral palsy proposed by such an eminent group of " interested people " in their letter of May 3, I do feel that the second explanatory footnote (which reads, " This excludes such quantitative disorders of movement as might be met with in mental defectives ") is both misleading and unjust If we are to have strict definitions about cerebral palsy let us also be clear about mental deficiency

Other " interested people ", like myself, whose work lies with patients suffering from " damage of the brain from intrinsically or extrinsically caused development disorder (occurring in fœtal life or after birth) or perinatal, paranatal or postnatal in origin " (footnote 4), do not call their patients mental defectives or think of them as such Mental deficiency is a legal term, not a diagnosis

It is a great disappointment to us that pædiatricians and neurologists continue to perpetuate, along with nearly all the rest of the medical profession, such misunderstanding They regard all brain damage severe enough to preclude educability as " mental deficiency " and an invidious distinction has grown up between cerebral palsy and mental defectiveness, whereas we know that it is quite possible for a child with cerebral palsy to be deemed, quite correctly, ineducable and, therefore, mentally defective This child is not suffering from some other disorder superimposed on his cerebral palsy, His " non-progressive brain damage " is merely more severe

In exactly the same way the child showing quantitative disorders of movement, which excludes him, by the definition, from the " cerebral palsy " group, is suffering from either brain damage which may also fit quite well into footnote 4 of the definition or from some other physical disorder—e g, metabolic He is not, however, suffering from mental deficiency

I earnestly hope for the closer integration of " mental deficiency " (sic) with general medicine, and this will not come about as fast as it might so long as the severely damaged child suffering from an obvious, clear-cut physical disorder is suddenly labelled " mentally defective " by the general hospital physician and instant dispatch to an " institution " advised

TREATMENT OF ASTHMA AND HAYFEVER BY HYPNOSIS

SIR,—The article by Dr Mason and Dr Black (April 26) is of considerable interest, but attention must be called to a serious misinterpretation of results at one point.

A series of skin tests with pollen extracts performed at weekly intervals in one small area of the body (the left forearm) could not fail to produce a gradually increasing hyposensitisation of the skin of that area irrespective of whether the patient was receiving hypnotic treatment or not. The random tests on the leg gave the true picture. The statement which they make that suggestion under hypnosis directed against her hayfever and asthma symptoms only, could inhibit *selectively* the allergic or atopic reaction in different parts of the body is therefore based on false premises. In their experiment there is no valid evidence that the skin responses were altered until specific hypnotic suggestion to that effect was made. That this could occur had been clearly shown many years ago by Clarkson [1] and Marcus and Sahlgren.[2]

Further investigation of the effect of hypnosis on the allergic skin reaction would be of great interest and might help to determine the point at which it acts. Might I suggest that a fruitful line of inquiry would be to determine the effect of histamine-induced weals. If a series of histamine dilutions ranging from 1/10,000,000 to 1/10,000 is used as testing material a clear-cut endpoint will be found in the normal individual. Dilutions up to 1/100,000 will usually produce a response, beyond that no reaction can be obtained differing from control saline. This test might be carried out on a patient before and after hypnotic suggestion. Another point which might be of interest would be to determine whether the Prausnitz-Kustner reaction could be abolished in a recipient who had previously received hypnotic suggestion.

Might I suggest that for recording of reactions it would be found less cumbersome if the area of wealing is outlined directly on to the patient's skin with a ball-point pen before the 'Sellotape' is applied? A perfect transfer can then be obtained and can be kept as a permanent record for photography or other means of measurement.

Liverpool D. BLAIR MACAULAY

SIR,—When the course of a chronic illness which has proved resistant to years of conventional treatment is reversed when treated by hypnosis, this seems good evidence to both patient and doctor of the value of hypnosis. Other doctors, however, may remain unconvinced, Dr Pepys and Dr Freeman (May 10), for instance.

Hypnosis now needs to be tested by controlled studies conducted by accepted research techniques. The treatment of warts could provide satisfactory material for such a study, for photographs could provide objective evidence of the response to treatment. Hypnotic treatment could be compared with a placebo and with an accepted treatment, such as the application of CO_2 snow. Such a study could add considerably to our knowledge of clinical hypnotism. Much laboratory work is being carried out, but there seems to be little comparable serious clinical research. The B.M.A. subcommittee which reported favourably on the medical use of hypnotism [3] stressed the need for research and suggested five fields that might prove rewarding. They suggested that such research should be organised through university departments and research foundations. I trust that their advice is being acted upon and that this valuable technique of hypnosis can finally lose any stigma of quackery and become accepted as a normal medical procedure.

3. *Brit. med. J.* 1955, i, suppl. p. 190.

SIR,—It is nearly one and three-quarter centuries since Lavoisier composed the report of the commission of the Académie des Sciences appointed to inquire into the alleged cures affected by Mesmer, who had come to Paris from Vienna in 1778 and claimed that cures could be effected by animal magnetism or hypnosis. His remarks are so pertinent to present-day reports of clinical trials and claims of the therapeutic benefits of new and old remedies that they are worth quoting in some detail:

> "The art of drawing conclusions from experiments and observations consists in evaluating probabilities and in estimating whether they are sufficiently great or numerous enough to constitute proof. This kind of calculation is more complicated and more difficult than it is commonly thought to be; it demands a high degree of sagacity and is for the most part beyond the powers of the generality of mankind. *It is on the errors in calculations of this kind that the successes* of charlatans, sorcerers and alchemists are based, and so formerly were those of magicians, enchanters and all those in general who deceived themselves or who sought to take advantage of a credulous public. In medicine, especially, the difficulty of evaluating probabilities is greater. As the principle of life in animals is an active force increasingly tending to overcome all obstacles, so Nature, left to her own devices, cures a great many diseases, and when remedies have been applied, it is very difficult to decide how much is due to Nature and how much to the remedy. So, while the multitude considers the cure of the disease to be a proof of the efficacy of the remedy, the only *inference in the eyes of the judicious is a degree of* probability, more or less great, and this probability can be turned into certainty only by a great number of instances of the same kind."

It should be well known to all practitioners that the vast majority of persons with atopic disorders, such as asthma and eczema, will recover spontaneously sooner or later. Therefore, to discover whether any method of treatment is beneficial in this group of maladies it is essential that a properly designed therapeutic trial be carried out, with adequate controls, and the results subjected to *rigorous* statistical analysis before they are submitted for publication. *It is quite unwarranted of Dr Mason and Dr* Black to draw any conclusions as to the effect of hypnosis either on asthma or the skin reactions elicited by allergens, before and after hypnosis, in their *solitary* case of asthma in a housewife (April 26).

The fact that therapeutic claims based on a solitary case can still be published reveals a serious defect in the present-day education of the medical student, and it would seem that the time has arrived when we must insist that all medical students receive a course of instruction in elementary statistics and probability theory so that they will understand more about the *design of experiments* and the statistical controls necessary to evaluate the results *of clinical and other trials*.

Such instruction should well repay the nation in the shape of a reduced drug bill, and the practitioner himself will have to read fewer uncontrolled trials and unsubstantiated statements of success with new or old methods of treatment.

London, S.E.1 E. J. MOYNAHAN

*** Dr Moynahan has perhaps misunderstood the *purpose of the report and our reason for publishing it*. Since hardly anybody now doubts that symptoms of various kinds can be modified by suggestion, a "therapeutic claim" or recommendation of the method, based on a single case, would certainly have been inappropriate. On the other hand, 180 years after Mesmer reached Paris, nobody yet knows how suggestion works. If it can (as some believe) evoke or abolish physical lesions as well as symptoms, its effects should be demonstrable most conveniently on the skin, and the observations of Dr Mason and Dr Black form an interesting complement to (for example) J A Hadfield's apparent success in raising blisters by hypnotic suggestion[1][2] and R L Moody's observations[3] of bodily changes during an abreaction under 'Evipan' narcosis As was pointed out last week, the design of their experiment was such as to allow other interpretations of the results, but flaws of this kind are not unknown in quite large clinical trials conducted under the highest auspices Single observations can be significant, provided they are correct, and they may have to be made almost by chance if, as Dr Hadfield found, the results of experiments in one "susceptible" person may not be reproducible in others Whether or not Dr Mason and Dr Black are right in their conclusions, they seem to us to provide at least a novel approach to questions which have gone too long unanswered —ED L

ABSENCE FROM WORK ON A MEDICAL CERTIFICATE

SIR,—We learn from Mr Woodhouse's letter of May 3 that employers are preferring their employees to write their own "sick notes" This is going to deprive the general practitioner of practically the last aspect of his dying art—the "certification" of illness With child-welfare clinics looking after his youngest patients, maternity services caring for his mothers-to-be, hospital clinics treating his diabetics, epileptics, and skin cases, and their follow-up clinics taking care of his only "interesting" cases of physical disease, surely he must feel that if he is to practise any medicine at all he must exchange general practice for hospital practice

Many patients pester him to see a "specialist", and are unsatisfied until they do so to the average layman a specialist means a hospital doctor Let not the general practitioner covet the interesting medical life of the hospital doctor, however, for although the public may appreciate his importance, the Ministry take a different view When speaking of registrars (the backbone surely of the hospital service), Dame Enid Russell-Smith[4] makes the astonishing remark that in the Ministry "we do not feel that the hospital doctor is necessarily ready to be in full charge of patients" I would add that hospital doctors' salaries accord with this attitude

REGISTRAR (LATELY IN GENERAL PRACTICE)

RECORDING THE HEART-RATE DURING EXERCISE

SIR,—Your Occasional Survey (May 3) draws attention to the difficulty of recording the heart-rate during vigorous exercise While the electrocardiogram (E C G) is the only suitable signal source, it is impossible to reject unwanted muscle action-potentials by simple filtering without degrading the E C G potentials themselves

We overcame this difficulty[5] by using a differential amplifier to reject in-phase signals at the input stage, leaving the E C G with only a few random muscle spikes which could easily be filtered off The T waves were attenuated in the main amplifier and any tendency to count them as well as the R waves was finally eliminated by the trigger sensitivity control rather than by the adjustable "refractory period" We have found it convenient to record heart-rate with ventilation-rate and respiratory frequency on the same strip of paper

The cardiotachometer works reliably during violent muscular movement (running uphill on a treadmill), at rates up to the maximum so far encountered (200 beats per min) and in the presence of potential interference from sparking points, relays, and treadmill motor We feel that it brings closer the "technical finality" mentioned by your contributor than any of the devices he describes

ONE RADIOGRAPH TO EXCLUDE PLACENTA PRÆVIA

SIR,—In most cases of antepartum hæmorrhage the placenta is normally situated In a recent survey at this hospital of 130 such cases only 23 (17 7%) had placenta prævia Our aim in our paper (April 19) was to find a simple harmless method which in our hands would obviate the need for a long hospital stay in about 80% of these cases

In retrospect we found that a single lateral radiograph after the thirty-fourth week showed evidence of a normally situated placenta in 90 out of 107 cases Subsequent events confirmed that those 90 patients could have been allowed to return home with safety We would, of course, agree with Dr Reid (April 26) that a single lateral radiograph will not be infallible in excluding placenta prævia, and also think that it would be unwise to claim 100% success even with full radiological investigation It is perhaps unnecessary to stress that only the closest correlation between the radiological and clinical findings will avoid mistakes

We would point out to Mr Percival and Dr Murray (April 26) that in this series the overall error was 2 8%, and like these two contributors we have found that the errors have diminished with experience

Leicester General Hospital

J L FREER
D R CAIRNS

SIR,—For over five years I have been carrying out soft-tissue placentography using one film only and I should like to comment on the paper by Dr Earn and his colleagues in your issue of April 19 and the subsequent letters by Mr Percival, Dr Murray, and Dr Reid (April 26)

It appears to me that when soft-tissue placentography is discussed there is some confusion as to what exactly is meant by the term To me "soft-tissue placentography" means demonstrating the placenta, and with a suitable technique this can be done irrespective of the fœtal presentation I have never required the services of an obstetrician in the X-ray department for this type of examination While displacement of the presenting part is present in placenta prævia this is no guide to the diagnosis, displacement is frequently present without placenta prævia

I cannot agree with Dr Earn and his colleagues that in placentography no special skill or equipment are required With regard to equipment I consider a filter to be essential, otherwise a properly balanced film is unobtainable Having tried various filters I have found the water pillow to give the most consistent results, being flexible it moulds itself to each patient and sustains the abdomen in the true lateral position By using a sandbag the quantity of water under the abdomen of a small patient can be adjusted The radiography must be carried out with the greatest care, a repeat film should be a rare occurrence, and in this hospital all the placentography is done by the radiologists

So far I have not had Dr Reid's experience of finding a major degree of placenta prævia with a normal lateral radiograph, but lateral implantation, though fortunately uncommon,

NEW METHOD OF PHENOBARBITONE ADMINISTRATION

SIR,—I was surprised that Dr Pearson (April 19), in his comments on Dr O'Connor's paper (March 22), quotes the work of Butler et al [2] Butler claims that, in regard to the constancy of blood-levels produced, there is no significant difference between the administration of phenobarbitone in tablet and in 'Spansule' form I find this claim to be based, however, on most inadequate experimental evidence

Butler gave tablets of phenobarbitone at six-hourly intervals to 2 patients and measured the resulting blood-phenobarbitone levels at two, five, and nine hours after giving the first dose It is very doubtful whether, by doing only three assays to cover a twelve-hour period, he could hope to detect, with any certainty, fluctuations in these levels which might only last, for example, from ten to sixty minutes Surely, a serious study would call for assays to be carried out at least every half hour during the period of the experiment?

CAUTIONARY CARDS

SIR,—Your note on A New Cautionary Card (May 3, p 975) might cause some of your readers to infer that your original editorial remarks [3] went unheeded, and that our friends, the Americans, have beaten us to it once again May I therefore point out that it was largely because of your earlier remarks that this Company decided to issue special cards for distribution by clinics and consultants to patients undergoing long-term treatment with the anticoagulant 'Dindevan' (phenindione)

Two small cards contained in a transparent plastic wallet are issued One bears the patient's name and address, indicates clearly that he is undergoing treatment with the drug, and gives the name, address, and telephone number of the physician under whose direction he is taking it It is also clearly stated that this physician should be informed in an emergency and consulted before dental or surgical treatment is undertaken On the back of the card is a space for the insertion of the patient's blood-group

The second card was designed to meet the needs of patients who have been discharged from the hospital but still have to return to an outpatient clinic for regular prothrombin-time estimations and possibly readjustment of the dose This card bears columns for the insertion of the date, prothrombin time, and dose It also serves as an appointment card for the patient's next visit to the clinic

These cards have been available since last October and are being widely used by many anticoagulant clinics We have no information as to when our American colleagues introduced their cards What is important is that cautionary cards are available in Britain, and will be willingly supplied to any consultant or clinic requiring them

*** We are glad to draw attention (if belatedly) to this useful British initiative — ED L

DEATH OF A BOXER

SIR,—Dr Byrom (May 10) rightly draws attention to boxing as a source of serious injury and death There must be many who share his regret that so little is done to keep this matter before the public, especially before parents The facts are plain enough and the inference to be drawn from them is important

In many games there is a risk of injury Footballers and cricketers are occasionally killed Players accept these risks freely and the rules are partly designed to keep the chance of injury low Injury, when it does occur, is accidental It is otherwise with boxing In this sport alone it is the single purpose of the boxer to defeat his opponent and the best way to do this is by knocking him out The more we know about the structure and function of the brain the more we should understand the utter folly of allowing young people to sustain repeated head injuries Postmortem studies show that petechial hæmorrhages often accompany cerebral concussion and involve a loss of nerve-cells

There is another aspect of the question which is harder to write about because of the value judgments that are involved Overt aggression expressed in a socially acceptable form is apt to arouse strong emotions The spectators of boxing experience these emotions in a manner that apparently runs parallel with the severity of the beating being taken by the loser The cries for blood and for the coup-de-grace fall ill upon the ears of a civilised community when pain and suffering are at stake There are other ways of experiencing the relief that expressing these feelings can give

Anything that can be done to inform the public will help the time when boxing will cease to be regarded as a worthwhile sport Doctors and others who work with young people might well decide where they, as individuals, stand in this matter There is much that they can do

Charterhouse,
Godalming J A WAYCOTT

SIR,—Dr Byrom's letter recalls to mind the important annotation on cerebral injuries during boxing that appeared in *The Lancet* on May 27, 1950, and a letter from me that you kindly published on June 10 of that year (p 1089) In it, I urged that a referee should not hesitate to stop a contest in which a man was being severely punished and particularly when uneven skill made a complete knockout only a question of minutes or seconds Unfortunately this relative safeguard against serious cerebral injuries is not being universally practised

In an amateur boxing contest, which was televised last week, one opponent was described by the commentator as inexperienced and having had only twelve contests, and the other one as very tough and experienced and having had over one hundred contests, most of which he had won The disparity was soon obvious in the performance, but nevertheless the referee permitted the inexperienced contestant to continue boxing after he had taken two counts of eight seconds, with the easily predictable sequence that the poor victim was very soon knocked out completely and carried to his corner by his seconds

Until otherwise competent referees acquire the courage and judgment to stop such contests earlier, and until the crowds and the contestants learn to accept such intervention as wise and humane, boxing will continue to be associated with a greater degree of risk than is necessary

I put forward similar views in a letter to the *British Medical Journal* (of Jan 8, 1955, p 102) and concluded that in spite of such preventive measures of prudency "trials of skill, endurance, and courage will still remain in very full measure for those who enter the ring in combat."

STRAMONIUM POISONING

SIR,—It goes without saying that we patients must pay a price for the heroic doses of stramonium used in the treatment of parkinsonism (90–120 minims of the tincture, or 3 pills, t.d.s.). In my experience that price is vomiting of a peculiar nature.

The attack is heralded by 3–5 days' obstinate constipation, associated with some rectal flatus. It begins about midnight and may awaken the patient. Starting gradually, it works up to a climax when the vomiting is copious, after which it ceases abruptly. The vomit is dark brown and contains little, if any, food residue. The most characteristic feature is the vomiting of lengths of thick mucus, obviously the result of gastritis. The attack ends with the passing of three to five motions of normal size in 36 hours.

The way to avoid this unpleasant effect of stramonium is to keep the bowels open while giving this drug.

F.R.C.S.E.

A POSSIBLE MODE OF ACTION OF INTRINSIC FACTOR

SIR,—It is a matter of great interest that the oral therapy of pernicious anæmia has been successfully achieved by Dr. Heathcote and Dr. Mooney (May 10) with a vitamin-B_{12}-peptide isolated from a fermentation of streptomyces. One must bear in mind, however, that in the initial period of the therapy a relatively high dosage of vitamin B_{12} was used and that a daily oral dose of 100 µg of the vitamin itself will produce remission in patients with pernicious anæmia.

I find it difficult, however, to agree with the statement that the effectiveness of the peptide indicates the fact that intrinsic factor probably does not exist. On the contrary, it appears that there may now be another link in the chain of a series of observations indicating the possible role of the factor itself. It could be that it is concerned in the conversion of vitamin-B_{12}-protein complexes, which in themselves are not absorbed, to vitamin-B_{12}-peptide complexes which can be absorbed. This is supported by the fact that raw liver contains vitamin-B_{12}-peptides and oral therapy with this material is successful; here again one must bear in mind the question of dosage. Moreover, a vitamin-B_{12}-mucoprotein complex has been prepared from hog gastric mucosa[1] and proved successful in the oral therapy of pernicious anæmia whilst in an impure state, with further purification, clinical activity was lost. We have shown[2] that the original impure material contained a mucoprotein, which behaved on electrophoresis very much like our own intrinsic-factor preparations. It is interesting to note, therefore, that the vitamin-B_{12}-mucoprotein complex was effective in oral therapy only when given at the same time as material which could have been intrinsic factor.

Our own intrinsic-factor preparations[2] produce remission with only 5 µg vitamin B_{12} daily and do not have proteolytic activity. The particular type of activity envisaged in the conversion of a vitamin-B_{12}-protein complex into a vitamin-B_{12}-peptide complex would therefore involve intrinsic factor as one of the components of an enzyme system and not necessarily as the enzyme itself.

One very real difficulty in relation to the above suggestion is the fact that Holdsworth[3] has prepared a protein of molecular weight approximately 40,000, which complexes with vitamin B_{12} and is capable of bringing about its absorption. The vitamin-B_{12}-binding power is only half the theoretical value and it is possible that one half of the complex molecule plays a part in the intestine in breaking down the other half to a vitamin-B_{12}-peptide.

A. L. LATNER

GENETICS AND BLOOD MORPHOLOGY IN AMAUROTIC IDIOCY

SIR,—The occurrence of vacuoles in the cytoplasm of between 5% and 20% of the lymphocytes in juvenile amaurotic idiocy was first reported by Bagh and Hortling.[4] This was confirmed by Rayner[5] who also reported similar findings in the parents and some of the siblings of patients with juvenile amaurotic idiocy.

Further data have now been collected covering all patients with juvenile amaurotic idiocy who have been admitted to hospital during 1950–56 in Sweden. Their parents, siblings, nephews and nieces, and in-laws have also been examined personally by one of us (S. R.). For each individual at least 300 lymphocytes have been studied in ordinary Giemsa-stained blood-smears.

The results, which are given in the accompanying table, indicate that lymphocytes with vacuoles are an important sign of the disease. If present in small proportions (i.e., about 1–2% in a healthy individual, they indicate heterozygosity, but their absence does not disprove heterozygosity. Neither does their presence prove it, for vacuoles in the lymphocytes may be seen in other conditions—infectious diseases and at least some of the other lipoidoses. Whether or not heterozygotes for these also have vacuolised lymphocytes is at present being investigated here.

The utility of this sign can be seen in the following case. A brother of a patient with juvenile amaurotic idiocy married

LYMPHOCYTES WITH VACUOLES IN PATIENTS WITH AMAUROTIC IDIOCY AND THEIR CLOSE RELATIVES AND IN-LAWS

Category (relationship to propositi)	No. examined	No. with vacuolisation		Average % vacuolised lymphocytes
		observed	expected*	
Homozygotes (propositi — secondary cases)	29	29	29	17·7
Heterozygotes parents of propositi	43	31	43	2·1
Normal siblings	46	18	31	1·6
Normal nephews and nieces—both parents with lym. vac.	4	3	3	1·4
Normal nephews and nieces—one parent with lym. vac.	12	4	6	2·5
Normal nephews and nieces—parents without lym. vac.	10	1	0	1·3
In-laws married to siblings	14	1†	?	1·3
No. examined	158			

*Assuming manifestation in all homozygotes and heterozygotes and a fully efficient diagnostic method.

†This individual is the mother of the family reported in the text. This family, with the exclusion of the now diseased child, also appears in the 4th row of the table.

STAPHYLOCOCCAL INFECTION IN INFANCY

SIR,—I refer to the annotation on this subject in your issue of Feb 1 It is there stated that it is not known how long hospital epidemic strains taken home by mothers and babies persist in the community

In 1949 I published a report on a widespread outbreak of staphylococcal infections [1] originating in maternity units which were caused by what is now known as phage-type 57 but was then referred to as type W I there reported a number of instances of long persistence of the epidemic strain in families The following is an example

Family no 1 —" Baby developed pustules when 10 days old Boils on head at 90 days Mother had boils on hips Father had boils on neck when baby four months old Grandmother living with family also had boils on face and hands The baby developed further pustules when 10 months old and the grandmother more boils on the face swabbing this family gave the following results Baby, pustule and nose, W positive, Mother, throat and nose, W positive, father, throat, W positive, Grandmother, boil and nose, W positive "

Instances are there quoted of carriage up to eighteen months

During the past four years we have had several experiences of families carrying hospital-acquired types (particularly type 81), and intermittently developing boils, &c, for even longer periods of time

Vancouver, British Columbia

J C COLBECK

DUODENAL ULCER AND THE ABO BLOOD-GROUPS

SIR,—In 1953 Aird et al [2] demonstrated an association between the ABO blood-groups and cancer of the stomach, group A being significantly commoner in patients with the disease than in controls An increased frequency of blood-group O in patients with peptic ulcer was found also by Aird et al [3] and in patients with duodenal ulcer by Clarke,[4] and by Koster et al [5]

I have compared the distribution of ABO groups in patients with duodenal ulcer with that in healthy persons from the same localities The numbers are necessarily small, and the results can only be on the borderline of statistical significance, but individual series are often helpful, since large collected statistics of uneven accuracy may miss points of importance

Of 147 patients with a duodenal ulcer, 110 were of the same social class (Civil servants) The diagnosis was confirmed by serial radiographs The remaining 37 were all patients under the surgical unit of the Municipal Hospital of Athens, and were operated on by the same surgeon The ages of the patients ranged from 20 to 70 years

For the controls I selected 157 persons 110 were mostly friends and relatives of the patients, the rest were volunteer blood-donors registered in the blood-bank of the Greek Red Cross The patients and controls were inhabitants of Athens, but were born in different parts of Greece, and were probably representative of the whole population

In the patients with duodenal ulcer, in both sexes combined, the overall frequency of blood-group O was 42 1% and that of group A 40 1% (table I), the corresponding figures in the controls were 43 3% for group O and 42% for group A

TABLE I—BLOOD-GROUPS IN PATIENTS WITH DUODENAL ULCER

Blood group	O	A	B	AB
No of patients	62(*42 1%*)	58(*40 1%*)	22(*14 8%*)	5(*3 4%*)
Difference from % in controls	−1 2	−0 9	+2 8	+3 3

A statistical analysis of these results was made, comparing the frequency of group O in the controls and in the patients with duodenal ulcer The application of the test of independence, at significance level P=0 05, gave χ^2=0 92 This *indicates that the likelihood of a duodenal ulcer developing is no greater in group-O than in group-A individuals*

Table II suggests that group O preponderates in men with duodenal ulcer and group A in women with duodenal ulcer Similar results were found in the controls

TABLE II—GROUPS O AND A IN PATIENTS WITH DUODENAL ULCER

Sex and blood-group	Men		Women	
	O	A	O	A
No of patients	47(*44 3%*)	40(*37 7%*)	15(*36 5%*)	18(*43 1%*)

I analysed these data and found a standard deviation of 0 09 for the difference in group O between male and female Since the total number of patients was much greater than 50 I applied the test of Gauss–Laplace to the difference I found that t=0 83 and P=20 33

There is thus no real evidence of a difference in the frequency of distribution of group O between men and women with duodenal ulcer

I record my sincere appreciation of the help I received from Mr Const Athanasiadis, professor of statistics, High School for Financial Studies, Athens

Clinic of Therapeutics,
University of Athens

GEORGE PAPAYANNOPOULOS

ORAL DIURETICS

Mr JOHN H FINGERHUT, deputy managing director, Merck Sharp & Dohme Ltd, writes

" Your editorial on oral diuretics (May 10, p 1005) was noted with interest, and in particular the mention of our new drug chlorothiazide (' Saluric ') The basic N H S cost of 8 g of chlorothiazide was unfortunately incorrectly quoted This should have been 7*s* 6*d* and not 9*s* 10½*d* Your readers may like to know that the average basic N H S cost of chlorothiazide for maintenance treatment of patients with cardiac œdema is 3*s* 9*d* per week "

Medicine and the Law

Damages for Death After Penicillin

A farmer, aged 34, was known to be sensitive to penicillin, but by mistake a nurse gave him a penicillin injection and he died [1] Damages of £17,500 were originally claimed, but in view of the fact that the widow would inherit £5000 from her husband's estate, this figure was reduced to £12,500 with costs, to which the hospital board agreed

Obituary

JAMES HARPER

M A, M B Glasg, F R F P S

Dr James Harper, consulting surgeon in diseases of the throat, nose, and ear to the Glasgow Royal Infirmary, died on April 27

He was born in Glasgow and educated there At first he intended to become a teacher, and after graduating M A from the University of Glasgow in 1906 he went to Jordanhill Training College, but before he had completed his course there he made up his mind to become a doctor, and returned to the university to study medicine After graduating M B in 1909, he spent some years in postgraduate study abroad in Vienna, Berlin, and London, where he was a clinical assistant at the London Central Throat Hospital, the Golden Square Throat, Nose, and Ear Hospital, and the aural department of the London Hospital In 1916 he returned to Glasgow and joined the staff of the ear, nose, and throat department at the Royal Infirmary Three years later he became chief surgeon to the department

S Y, who was his assistant and successor, writes

Dr Harper's arrival on the Glasgow Royal Infirmary staff coincided with a new approach to diseases of the throat, nose, and sinuses At this time, the physician was largely replaced by the surgeon in dealing with these conditions, and Dr Harper's early pioneer work is still known to his colleagues He was, in addition, an enthusiastic teacher of his specialty and a close student of the association of infective throat, nose, and ear conditions with many aspects of general medicine Those of us who knew him found him an inspiring teacher and a keen exponent of clinical research

Dr Harper leaves a widow and four sons, three of whom are doctors

GERALD ROBINSON

F R C S

Mr Gerald Robinson, consulting surgeon to the South Devon and East Cornwall Hospital, Plymouth, died on March 20

He was born in London in 1882 and was educated at Marlborough College and Guy's Hospital, where he was awarded the treasurer's gold medal for clinical surgery in 1903 After qualifying in 1904 he held the appointments of out-patients' officer and house-surgeon at Guy's Hospital and clinical assistant at the Evelina Hospital for Sick Children He took the F R C S in 1907 and the same year settled at Plymouth in partnership with the late Dr Hughes In 1911 he was appointed assistant surgeon to the South Devon & East Cornwall Hospital During the 1914–18 war he served as a captain in the R A M C on the staff of the Fourth Southern General Hospital, Plymouth He was consulting surgeon to the East Cornwall Hospital, Bodmin, and to the Liskeard, Fowey, Kingsbridge, and Totnes hospitals He was president of the Plymouth Medical Society for a term

Outside his profession he had many interests An expert metal worker, he was a member of the Guild of Silversmiths He was also a skilful fisherman, a good shot with both shotgun and rifle—he competed at the National Rifle Association meetings at Bisley—and a keen ornithologist and wildfowler

Mr Robinson's first wife died in 1955, and he was married again in 1956 to Miss Helen Campbell MacLashan

G L P writes

Modest and retiring, and reserved almost to the point of shyness at times, Mr Robinson always avoided publicity, a trait that endeared him even more to his friends but one that was often misunderstood by those who did not know him so well There is an old saying, "A successful man is known during his lifetime but a great man is known only after his death" To be a great man and a successful man during a lifetime is surely the highest tribute that can be paid to one as deserving as Gerald Robinson

Prof GEOFFREY RAKE

E C-J writes

I knew Geoffrey Rake at two periods of his career In the first period, at Guy's Hospital in the twenties, he suddenly became a source of amazed admiration to his contemporaries As a student he was shy and retiring, though a persevering cross-country runner, and handicapped by a bad stammer His first-class intellect was slow in developing, so he had difficulty in passing his early exams The transformation came almost overnight, under the inspired and inspiring guidance of Adrian Stokes, then professor of pathology at Guy's Geoffrey shot ahead, and was soon laden with medals Success gave him confidence but did not improve his stammer, which remained an impassable obstacle to clinical practice He was obviously cut out for research, so nobody was surprised when he departed to the laboratories of Johns Hopkins

In the States—we heard years later—there was some confusion over his salary He was not the man to send out distress calls, and for a year or so he earned only a bare living wage I do not know the details, but it was a grim business that probably left a permanent mark on Geoffrey's character

In 1952 I met him again He was then director of research of the Squibb Institute in New York He had played an invaluable part, I believe, in the American development of large-scale penicillin production, in collaboration with Fleming and Florey I had met him only once or twice, at reunion dinners, since we both qualified But when I tied myself into a financial bow-knot through miscalculating the cost of living in the United States, a phone-call to Geoffrey's New York office brought his immediate and generous aid He descended on our hotel (my family was over for a few weeks), like a fairy godfather, and wafted us all away to stay with him in New Jersey

Millstone, where the Rake family lived, is a colonial township made of wood, painted a brilliant white The houses are mostly made of overlapping oak boards, like old Kent cottages, and the church is a wooden replica of the Wren churches in the Strand The Rakes lived in "Main Street"—there was one shop and (I think) two other houses in it—and Geoffrey was the mayor This was a serious appointment and Geoffrey took it seriously It seemed to us that he took everything too seriously Miraculously, he had entirely overcome his stammer But the fifteen years had changed him into a grimly determined man, with a single-minded interest in the development of the antibiotics, which he shared with his near neighbour, Professor Waksman, of Rutgers University, of streptomycin fame, with whom we occasionally commuted from New Brunswick to New York

Notes and News

AN ALL-IN FAMILY SERVICE

The problems and needs of the family are causing concern today, but the Council for Children's Welfare and the Fisher Group, in a pamphlet[1] based on their evidence to the Ingleby Committee, point out that among all our social services there is none with a special responsibility for the family as a unit. At present different services deal with the different problems of different members of the family, and too often the underlying factor which may be causing ill health, delinquency, or even disruption of the family goes unrecognised and untreated. These independent, self-contained services tend to cause delay, duplication, and lack of continuity in the help they offer, and because each has been set up to deal with a particular need, they are usually remedial rather than preventive. The Council and the Group agree that the committees which coordinate the work of the different services of the local authorities and voluntary organisations have proved valuable, but in their view coordination can never be a substitute for a concentration of responsibility. They therefore propose that a family service should take over the existing children's departments, and extend their work from the care of deprived children to the care of the family as a whole.

The help of the proposed service would be available to any family, whether self-reliant or inadequate. It would seek to safeguard the social wellbeing of the family and offer help to the "well" family exposed to strain as well as providing early treatment for the "sick" family. It would work in close cooperation with the present health, education, welfare, and youth employment service, and it would hope to find families in need of support through school officers, teachers, and family doctors. It would have pleasant local offices which parents would be encouraged to visit for help and advice. The new service, it is suggested, might be run by a family care committee for each local authority and it would be appropriate for it to come under the general supervision of the Home Office.

The idea of offering the family more support from fewer hands is attractive, but the proposed new service would apparently still turn to the other social services for specialist help. Each time it did so, it would in effect be putting another caller on the family's doorstep. It would best justify its existence by reducing the family's need for such outside help. It would require, its sponsors believe, legislation before it could be started, and then it would be necessary to find social workers to clothe its administrative bones. In the meantime many local authorities have already arranged for some of their workers to take a special responsibility for their problem families as families, and, as Dr Scott's recent London survey[2] showed, have made at least a beginning with preventive work among them.

REWARDS AND MERIT

Speaking at the conference of the Institute of Hospital Administrators in London on May 5, Sir James Lythgoe said that in attracting staff the National Health Service, with limited and often restricted resources, would, even in normal times, and still more in times of inflation, be at some disadvantage when competing with the large flexible resources of industry. This disadvantage could be increased if the service was also encumbered with an unduly rigid code of rules and regulations, and he believed that it was especially important to give those who were running it as much flexibility and freedom of action as possible. If the service was to compete effectively for people of ability and enterprise he believed that there should be less emphasis on guaranteed uniform treatment regardless of zeal and efficiency, and greater emphasis on differentiated rewards. He would like to see less fragmentation of salary scales and greater opportunity to recognise ability by acceleration of increases within scales, more use of merit awards beyond normal maxima, and "also power to retard advancement (and use made of it) in cases of unsatisfactory performances of duties or lack of zeal. Salary scales, as they have evolved in the public services in recent years, give insufficient opportunity to reward merit on the one hand or penalise inefficiency on the other."

HOSPITALS 1948-58

Opening the same conference and the International Hospital Equipment and Medical Services Exhibition in London on May 5, Mr Derek Walker-Smith, the Minister of Health, said that on July 5 ten years ago nearly 3000 hospitals were taken over by the Ministry. Some of them were world-famous, with fine standards and traditions, but many left much to be desired. Nearly all had suffered from inevitable neglect due to the war and its economic aftermath. Many beds were closed because of shortage of staff. "Because the amount of resources that could be devoted to the hospital service had to be and remains inevitably limited, these ten years have essentially been a period of renewal and redeployment rather than of wide expansion. But it has been a fruitful period in which much progress has been made in improving the service, both from the point of view of quantity and quality. In the sphere of hospital construction and improvement we are going actively ahead in spite of economic limitations. The last few years especially have seen a gratifying rise in the amount of money available for this purpose. In money, there was been an upward curve as follows: 1955-56, £10 million, 1956-57, £13 million, 1957-58, £18 million, 1958-59, £20 million, 1959-60, £22 million. Many old hospitals have been improved and upgraded to provide a district service with a full range of specialties. The number of consultants has increased by nearly 33%—from 5191 at the end of 1949 to 6902 at the end of 1957. Between 1949 and September, 1957, the number of available staffed beds rose from 448,000 to 474,500—an increase of 6%. Much more significant and important than the rise in the number of beds is, however, the rise in the use made of them. It is an indication, at least in part, of efficiency in management that the increase of 6% in the number of available beds has been accompanied by a rise of 27% in the number of inpatients treated."

STRESS IN GENERAL PRACTICE

Last October a joint conference was held of the London faculties of the College of General Practitioners and the Society of Psychosomatic Research. We gave some account of the proceedings[1] which have now been published verbatim.[2]

MIDDLESEX HOSPITAL MEDICAL SCHOOL

Among the new English medical-school buildings will be that of the Middlesex Hospital, for work has begun at a corner of New Cavendish Street.[3] The first phase will cost all the £970,000 that has so far been raised through donations, grants, and covenants; it includes a block of five storeys to house teaching laboratories, lecture theatres for all the preclinical departments, a more spacious lecture theatre seating 400, and a physiology demonstration room of circular stepped design. This block will be complete in September, 1959, when the council hopes to have raised the £530,000 needed for the next phase—an eight-storey block containing research laboratories, common-rooms for students and staff, and a diningroom. Later still, a residential college is planned, with rooms for a third of the school's 450 students. The new buildings will be grouped round a courtyard with a fountain and flowers; they should prove much more convenient and pleasant to work in than the present cramped, scattered, and unplanned quarters.

CLINICAL PSYCHIATRIC UNIT AT SHEFFIELD

As a joint venture of the board of governors of the United Sheffield Hospitals and the University of Sheffield, a department of psychiatry has been established under the direction of Prof E. Stengel. It was started in a limited way in 1956 with a 7-bed ward unit at the Royal Infirmary and outpatients clinics at the Royal Infirmary and Royal Hospital A main clinical unit has now been provided by converting a former reablement centre at a cost of £75,000, to be met in part from the board's capital allocation from the Ministry of Health and in part from the board's endowment fund

[3] *Times*, May 9.

The unit is pleasantly situated in semirural surroundings on the outskirts of Sheffield and stands in its own spacious grounds It has 29 beds in small wards, and a treatment unit Built-in fittings include a patient/nurse call system As many of the patients will be up and about during the day, a hanging clothes locker has been provided for each patient Each ward has its own patients' sitting-room, with writing-tables, wireless, and television On the ground floor one wing has been equipped as a diagnostic and therapy centre for outpatients and accommodation is provided for a day hospital where patients can attend for treatment during the daytime, returning at night to their own homes A communal dayroom and diningroom have been included for the use of inpatients and those attending the day hospital A sliding partition between these two rooms can be opened to make a room large enough for film shows and group therapy The interior decoration has been chosen to give a calm and restful effect in wards, with a bold use of colour and design in other areas to produce a stimulating contrast A sectional hut will house the occupational therapy department at the rear of the clinic Residential accommodation has been provided within the building for medical, nursing, and domestic staff, and on the top floor rooms have been set aside for research

APPROVED NAMES FOR DRUGS

THE British Pharmacopœia Commission has issued the following new supplementary list of approved names

Approved name	*Other names*
Chlorphenoctium Amsonate	2 4-Dichlorophenoxymethyldimethyl-*n*-octylammonium amsonate (Amsonic acid is adopted as the trivial name for 4 4′-diaminostilbene-2 2′-disulphonic acid)
Chlorproguanil	N^1-3 4-Dichlorophenyl-N^5-*iso*propyl-diguanide Lapudrine is the hydrochloride
Dextromoramide	(+)-1-(β-Methyl-γ-morpholino-*αα*-diphenyl-butyryl)-pyrrolidine Jetrium, R 875
Dimethicone	A polydimethylsiloxane
Ethotoin	3-Ethyl-5-phenylhydantoin Peganone
Hydroxychloroquine	7-Chloro-4-[4-(*N*-ethyl-*N*-2-hydroxyethyl-amino)-1-methylbutylamino]quinoline Plaquenil is the sulphate
Isothipendyl	10-(2-Dimethylaminopropyl)-10-thia-1 9-diaza-anthracene Nilergex is the hydrochloride, Theruhistin is the hydrochloride
Levomoramide	(-)-1-(β-Methyl-γ-morpholino-*αα*-diphenylbutyryl)-pyrrolidine
Norethisterone	17β-Hydroxy-19-norpregn-4-en-20-yn-3-one 17α-Ethynyl-17β-hydroxyoestr-4-en-3-one 17α-Ethynyl-19-nortestosterone Norlutin, Primolut N
Pecazine	10-(1-Methyl-3-piperidylmethyl)pheno-thiazine The name Pacatal is applied to the hydro-chloride and the acetate
Perphenazine	1-[3-(2-Chloro-10-phenothiazinyl)propyl]-4-(2-hydroxyethyl)piperazine Fentazin, Trilafon
Phenactropinium Chloride	*N*-Phenacylhomatropinium chloride Trophenium
Poskine	Propionylhyoscine Proscopine is the hydrobromide
Racemoramide	(±)-1-(β-Methyl-γ-morpholino-*αα*-diphenylbutyryl)-pyrrolidine
Ristocetin	Antimicrobial substances produced by *Nocardia lurida* Spontin contains Ristocetin A and Ristocetin B
Salinazid	*N*-*iso*Nicotinoyl-*N*′-salicylidenehydrazine Nupa-sal
Sulphaproxyline	N^1-(4-*iso*Propoxybenzoyl)-*p*-aminobenzene-sulphonamide
Tacrine	5-Amino-1 2 3 4-tetrahydroacridine
Triamcinolone	9α-Fluoro-11β 16α 17α 21-tetra-hydroxypregna-1 4-diene-3 20-dione 9α-Fluoro-16α-hydroxyprednisolone Aristocort, Ledercort
Tropigline	Tiglyltropine

FRIENDS SERVICE COUNCIL

THE Council's report[1] for 1957 gives some idea of the variety of work done in Europe, Asia, and Africa—houses have been built, schools and training institutions carried on, water supplies extended, displaced villagers resettled, refugees cared for, clothing distributed The medical work of the Council has included tuberculin tests and B C G inoculations, health education, and antenatal and postnatal clinics in South Korea—where the medical programme closed in December—and the training of nurses and the building of a new tuberculosis ward at a mission hospital in Kenya The Council (Friends House, Euston Road, London, N W 1) invites legacies, donations, and covenanted subscriptions to enable it to continue its work, expenditure exceeded income by £10,786 last year, and the deficit this year is expected to be about £15,000, which will make serious inroads into its legacy reserve fund

University of Oxford

On May 1 the degree of B M was conferred on M F Burfoot

University of Birmingham

The university will hold a degree congregation on July 17 on the occasion of the annual conference of the British Medical Association in Birmingham, over which Prof A P Thomson, dean of the faculty of medicine, will preside The honorary degree of LL D will be conferred on Lieut-General Sir Alexander Drummond, the honorary degree of D SC on Dr J S Mitchell, regius professor of physic in Cambridge University, and the honorary degree of M D on Dr I D Grant, president of the College of General Practitioners

Dr Jean Mackintosh at present part-time reader in the department of pædiatrics and child health has been appointed to a full-time post in the department of social medicine for three years from July 1 She will undertake an investigation to be financed by a grant from the Nuffield Provincial Hospitals Trust into administrative problems in the public medical services particularly under the National Health Service Acts

University of St Andrews

Lord Kilmuir, rector of the university, opened a research unit for midwifery, gynæcology, orthopædic surgery, anæsthetics, and dermatology in Dundee on May 3 The unit is housed in a former students' hostel in Dudhope Terrace, and Prof R B Hunter, dean of the faculty of medicine, said that people might wonder why these buildings were being put up away from the college The reason was that in ten years they hoped to have a new medical school and hospital The research units were being started as "islands of excellence" where people could be trained to staff the new institution

Royal College of Surgeons of England

At a meeting of the council on May 8, with Sir James Paterson Ross, the president, in the chair, it was announced that Sir Russell Brain had accepted the honorary fellowship of the college

The Jacksonian prize was presented to Mr B B Milstein A Hunterian professorship was awarded to Mr J Bryant Curtis (Melbourne), and the Begley prize was awarded to Mr Robert Cohen (London Hospital Medical College)

Postgraduate diplomas and diplomas of membership were conferred on the candidates named in the report of the comitia of the Royal College of Physicians (*Lancet*, May 3, 1958, p 975) Diplomas of membership were also conferred on D L Common, Maxwell Lindsey, and A R Molyneux

Royal College of Physicians of Edinburgh

At a meeting of the college on May 6, with Dr A Rae Gilchrist, the president, in the chair, the following were elected to the membership

J B Stanton J A Simpson, K K Das Gopal Sharan A K Ganguly, J A M Joyce William Davison, W F K Morrow N S Capstick, Mohammed Siddique S K Vaish Nellie P Fernando, N W J England, T O Ogunlesi P E Goonewardena N J Shah E M Salama Keitha Corlett N A E Samaan, P J Koblenzer, Neville Berlyne, C R Maddock, J D Todd, John Stevenson, G I G Joag, D J Patel Iftikhar Ahmad, A D Cameron N H Korner, N B Sabiel, F E Udwadia A J Gazder, M W McNicol S S Rikhy, Iqbal Ahmed, P C Nag, M A Qureshy, D A Whiting B K Roy, B D Patel

[1] Friends Service Council Report for 1957 Pp 24

Royal College of Surgeons of Edinburgh

At a meeting of the college on May 9, with Prof John Bruce, the president, in the chair, the following were admitted to the fellowship

E G Ahern, R M Anderson, M S Bansel, J S G Blair, P S Boulter, M C Deaa, W M Hefni, T V Hingorani, E A Ingram, Harold Jackson, M M A Kader, B H Kelham, J R Kirkpatrick, Phillip Lebon, W W J Liddle, W A A G Macbeth, G B McKelvie, M R Morris, D A O'Rourke, L S Parker, B C Paton, G G Powell, G L Ritchie, J W Rodwell, J B van Schalkwyk, B P Scrivener, S J Seevaratnam, M M Sinclair, Keshmahinder Singh, Lucas Souvlis, N W Struthers, J D Thompson, J C Usdin, G A Whitefield, D B B Whitehouse, W W Wilson, C I Woolf, M K A Youssef

European Association Against Poliomyelitis

The next meeting of this Association will be held at Madrid from Sept 28 to 30 Further information may be had from the secretary of the U K Committee for Poliomyelitis, Royal College of Physicians, Pall Mall East, London, S W 1

Advisory Committee on Medical Research in Scotland

The Secretary of State for Scotland has appointed the following five new members to this committee Prof Dugald Baird, Prof D M Douglas, Prof T Ferguson Rodger, Prof E J Wayne, and Dr D J Finney

Nursery School Association

This Association is holding a conference at County Hall, London, S E 1, on June 20 at 9 45 A M The theme is to be Mens Sana—the Real Foundation Further particulars may be had from Dr David Morris, 1, Park Crescent, Portland Place, London, W 1

Surgery of Leprosy

The Friends of Vellore are holding a meeting at 1, Wimpole Street, London, W 1, on Wednesday, June 18, at 5 15 P M, when Mr Paul Brand, of the Vellore Christian Medical College, South India, will speak on reconstructive surgery in leprosy

The International Children's Centre

For doctors this centre is organising a course in nutrition, to be held in Paris for four weeks from Sept 15 The course will be in French Applications should be sent to Dr Nathalie P Masse, director of studies of the centre, Château de Longchamp, Bois de Boulogne, Paris 16e

Society of Medical Officers of Health

Teaching Group—This group, which has lately been set up under the chairmanship of Prof Fraser Brockington, is to hold its first conference on June 13 and 14, at the Ciba Foundation, 41, Portland Place, London, W 1 The speakers will include Prof Thomas McKeown, Dr J M Mackintosh (future of the medical services and its implications for the teaching of social medicine), Dr C W Dixon, Dr J B Meredith Davies (content of social medicine), and Prof Alexander Mair, Dr John Burton (teaching methods) Further particulars may be had from the secretary of the group, Dr Burton, Central Council for Health Education, Tavistock House, W C 1

Medical Student Journals

Last Saturday a conference of editors of medical student journals was held at B M A House in London by the British Medical Students' Association Mr Michael Hall, editor of the *British Medical Students' Journal*, took the chair, and at the morning session talks on editing and on printing were given by Dr T F Fox and Mr John Hunter The afternoon session was opened by Mr M Cozens, of the advertisement department of the B M A, and editors and representatives of student journals then gave shorter communications In the evening members of the conference were entertained to dinner by *The Lancet*

Dr John Burton has resigned from the medical directorship of the Central Council for Health Education, and Dr A J Dalzell-Ward, who has been deputy medical director of the council since 1952, will succeed him

On Friday, May 30, at 8 30 P.M, at the Southend General Hospital, Mr Rodney Maingot will give the *Sydney Body* lecture for 1958 He is to speak on surgery in art

Colonel J B George, late R A M C, has been appointed honorary physician to the Queen, in succession to Major-General Douglas Bluett, who has retired

Dr G H Wright, of King's College, university lecturer in anatomy has been elected into an official fellowship at Clare College, Cambridge

Mr V B Green-Armytage has been promoted to be an officer of the Legion of Honour

---

CORRIGENDUM—*The Treatment of Sports Injuries* Copies of this film, which we reviewed last week (p 1029), may be had, free of charge, from Smith & Nephew Ltd, Medical & Technical Information Department, Bessemer Road, Welwyn Garden City, Herts

FEAR IN HOSPITAL PRACTICE

SOME ADVANTAGES OF HOME CARE *

E. M. BLUESTONE
M.D. Columbia

CONSULTANT, MONTEFIORE HOSPITAL, NEW YORK CITY

> "The fear of death is more to be dreaded than death itself."—
> PUBLIUS SYRUS

ONE of the chief characteristics of good physical and mental health is the ability to minimise the effects of fear. As health forsakes a man, the everyday fear associated with normal living is intensified. It makes a bad situation worse and the patient needs help in dealing with it. The complicating and enervating dread in a sick man may nullify any treatment that does not take into account his mental reaction to his illness. Yet too often this is overlooked, minimised, or even disregarded.

The patient who seems apprehensive before, during, or after diagnosis or therapy (whether or not he is in the confidence of his doctor, but most often when he is not) is, for all practical purposes, under the influence of fear. Because fear, unlike worry or anxiety, both of which it includes, requires an antagonist to evoke it, the word is seldom found in the terminology of physical disease, as if the doctor were afraid that his prestige might somehow be impaired by the mention of it. But nobody has the right to be offended by the presence of fear in his patient. Illness is a humiliating experience, and the more critical the patient's condition (up to, and including, the point of dying) the more it offends his dignity. It is normal for a person to glory in his strength, and when this precious asset leaves him, he fears that it may not return, or that he may have to pay a crippling price for its return. Even irritability or impatience during illness has an element of fear in it. Courage depends on the will to regain the health that has been lost, and the sick man is fearful that he may not succeed, or be helped to succeed, in this struggle.

Fear is aggravated when the patient is kept in the dark about his condition, or when he is left too long with his own thoughts. It is by no means restricted to the literate, but may strike most heavily the less enlightened, the ignorant and the superstitious. One has to be extremely careful in distinguishing "exaggerated" fear from "justifiable" fear. Age is a factor, since older people are closer to death and very few of us can face oblivion calmly. Again, the greater the patient's weakness—and this is true at any age—the greater his fear, which will be increased, too, if there is danger of him or his family being later reduced to social dependence. The only patient who is entirely free of fear is the unconscious patient. Helplessness, inability to manage one's own affairs, and the need to be babied during illness all have their depressing effect. Vespasian remarked that an Emperor should die standing!

In contrast with physical pain fear lies beneath the surface, and too often in hospital its existence is denied or played down. Physical signs, such as pain, fever, shock (which, in some respects, is a physical manifestation of intense fear), unconsciousness, or hæmorrhage, compel a medical response. Those which can be suppressed or contained (at some cost) may go unmollified or untended though the damage which they cause may be as great, and perhaps less endurable. Illness is always a traumatic experience. It leaves its mark and sometimes this is an irreversible scar.

An analysis of fear is an easy exercise in a hospital if only because of the abundance of clinical material. In its most challenging form it is to be found in the newly admitted patient and in the one awaiting his summons to the operating-table. It follows no established psychological pattern and is aroused by any stimuli which, rightly or wrongly, are interpreted as a threat to life or comfort.

Kind Words as Therapy

Here is a serious hospital problem which must be identified early and solved for each patient. If the doctor moves, or stands still, on the assumption that his patient's mental state will somehow improve so long as his physical ailment is being relieved, the patient must bear his deprivation as best he can. To greet a new patient, or any patient at any time of his illness, with impersonal silence that may be misinterpreted as lack of sympathy, is a self-defeating kind of neglect. The doctor must bear in mind that the patient who is before him is not a cold figure, or exactly the one who was included in past statistics of the same illness.

My mind goes back to the way the late George W. Crile used to prepare a patient for thyroidectomy. He knew that the patient was his best ally in the surgical victory which he was planning, and he did everything in his power to win the patient over and put his mind at rest before operation. The busy surgeon, the impatient surgeon, the man who expects his word (even when it cannot be heard) to be taken unquestioningly as law by the patient and his fretful family, the one who deputes such intimate duties on the assumption that confidence—another antidote to fear—can be won that way, are still among us as are, indeed, their counterparts in the medical specialties. Silence can be very harmful at times, particularly when it is wielded by those who are expected to carry healing in their hands. It may well be interpreted by the disturbed mind of the patient as a sign of therapeutic weakness, and, if a mistake has been made in assigning such a doctor to him, what is he to do? As for the administration of tranquillising drugs as a substitute for the spoken word, this resembles the administration of antibiotics while neglecting surgical asepsis. Actually it may be easier to administer therapy independently of the psychiatrist for such a secondary complication as fear than for the primary physical disability, and failure to cope successfully with the disability is no excuse for leaving the patient's fear untreated. We must be on our guard lest medical negativism and the tendency to let Nature take its course should breed callousness—the callousness evident in anyone who turns his back on an apprehensive patient. You cannot help a drowning man from a distance—you must come close to him.

Every conscientious doctor can bear witness to the exhilarating effect on a patient when the kind word is spoken at the strategic moment. If a patient can be told the good news in advance so much the better. There is no need to wait for statistical evidence based on a series of cases before applying remedies which are as potent as the balm of Gilead. Those who serve the sick, must

---

* Based on an address on May 13 to the Bristol division of the British Medical Association.

have insight as well as foresight, and evaluate each case psychologically, on its merits For this they need time, patience, sympathy, and cooperation from the hospital authority, as well as encouragement Their prescriptions are as valuable in overcoming the symptom of fear as in overcoming basic and original symptoms of the illness The surgeon who never sees his patient in the conscious state after an operation may have performed a mechanical job brilliantly, but the patient will be relieved of his fear only by humane reassurance and personal interest Though statistics will not help a man who is dying, kind words will do so, and they should be used liberally Enough is seldom done

In hospitals today we see growing interest in the patient as an individual—more privacy, "rooming-in" for mothers, more liberal social service, easier hospital visiting hours, more information services, rehabilitation schemes, and the like But the problem in essence is how to give each patient the comforting feeling that he has little to fear because everything known to science and humanity has been mobilised for his special benefit Where there is hope it must be stimulated, where there is no hope it must be simulated Never laugh at a placebo, emotion sometimes plays as big a role in illness as logic, and must be treated with equal therapeutic skill even if the remedy is only palliative

Hospital and Home

The situation is complicated by another kind of fear which sometimes overtakes those who look after the patient whether on their own timorous account or because of the demands which the sick man may make on their time and energy Fear is felt not only by the patient but to some extent by the doctor who prescribes for him, by the social worker who supplements his medical care with information on such subjects as fear, by the administrators of the hospital who may have difficulty in living up to its ideals, and (last but by no means least) by the worried and anxious family of the patient

Removing a patient from his own home, however modest it may be, and transferring him to a hospital where he must compete with other ill, and possibly more gravely ill, people for attention—where, since he is outnumbered, he feels himself in a minority—is not always therapeutic We must remember that every mother is a good nurse but not every nurse is a good mother When a patient enters the hospital he faces the unknown He is a stranger among strangers, exposed to them as they are to him, in all their weaknesses, demands, and variable requirements In this case it is not true that "misery likes company" The doctor's first thought, and indeed the first thought of the hospital should be, wherever his illness allows it, to keep the patient in his own home, supported by a subsidy from the community (if need be) and in any case by the continued interest and help of the hospital The impersonal, mechanical, routinised institution of collective care is more likely to arouse fear than to relieve it, and too often the fear is justified The multiple-bed open ward in hospitals is an invitation to oversight and neglect It encourages overt selectivity in a busy doctor, or one with limited interests There is wisdom in Libman's suggestion that every hospital should have a rule that a staff doctor during his rounds should sit down for at least one minute by the bedside of each patient

These are the compelling reasons which prompted me to plan and establish a modern extramural hospital service to supplement the intramural service[1] Home care controls and limits fear while respecting the dignity and essential privacy of the individual It also saves hospital beds for more intensive use by those who cannot do without them and reduces the total community bill for medical care When medical care is properly apportioned, between hospital and home, the advantages to the patient, his doctor, and the hospital are legion Lessons in individual care are learnt more rapidly and applied within the hospital proper

The hospital has reason to fear the consequences for the patient of some of its inadequacies It is too often short of staff—and particularly of intelligent, considerate, and helpful staff It is often short of vital space It deals with patients *en masse*, in open wards, and large numbers increase the chances of error It deprives the patient of privacy and subordinates him to the needs of his neighbours in the same sickroom (and outside it) It can seldom provide him with the food to which he is accustomed, or permit his relatives free entry to his bedside It must too often deny him information about his condition, for lack of time when serving large numbers and not often because it does not know what to tell him From the point of view of too many hospitals, the best patient is the one who is admitted with a quickly curable condition, accepts everything without question, and does not complain

A good home-care service based on a hospital can do much to relieve, if not to abolish, these shortcomings Furthermore it allows the hospital doctors and the family doctors to work together The family doctor holds many keys to the solution of his patient's problem, and he should have the benefit of hospital facilities (staff and equipment) in his patient's home wherever this is preferable and practicable The hospital staff is at its best with the more technical problems of medical care which require the transfer of the patient to the hospital The family doctor should be welcome on both sides of the hospital wall and be accepted as a member of the team looking after patients

* * *

Hospitals must advance with medical and social science They must deal with their own built-in handicaps and, in doing so, help to overcome fear from whatever source We know now how this can be done The distant château-hospital fortified against intrusion belongs to the past

---

[1] Bluestone, E M *J Amer med Ass* 1954, 155, 1379

" Many girls who have perfect feet at their ten-year-old examination have severe deformities by the time they reach school leaving age, many of such a degree that they may eventually require operative treatment The present day fashion of continued all day wear of shoes of a 'slip on' or 'casual' type, which must of necessity be too small so that they can stay on, or cause cramping of the toes to keep them on can during these formative years cause hallux valgus, painful bunions and curling under of the toes, sometimes of such a degree that the nails are walked on From an economic aspect only it is doubtful if in years hence the country can afford comparatively young, middle aged, and elderly women hobbling round on deformed feet The strange fact is that the young girl of today, who would laugh at a whale bone corset of Victoria days, treats her feet in the same way as her great-great-grandmother treated her waist "—Dr R G DAVIES, annual report on the school health service, Huddersfield, 1957

THROMBOSIS OF THE INTERNAL CAROTID ARTERY

SIMULATING AN INTRACRANIAL SPACE-OCCUPYING LESION

Although thrombotic occlusion of the internal carotid artery was described almost three hundred years ago (Willis 1664), its frequency and clinical importance are only now being established, owing to the introduction of cerebral angiography and to wider awareness of the disease. In five years Webster et al. (1956) encountered 70 cases in clinical practice, whereas Johnson and Walker (1951) found only 100 examples in the literature of the preceding fifteen years, Sastrasin (1957) has surveyed graphically this increasing incidence over twenty-three years in a large neurosurgical clinic. Furthermore, Panter (1957) reports 5 cases amongst 306 cerebrovascular accidents in almost 15,000 hospital admissions during a six-year period, and Fisher (1954) has recently found 45 examples in the routine necropsy material of two years

The clinical picture of internal carotid thrombosis is now well known, but certain aspects of it deserve more detailed consideration. Thus an important mode of presentation is that which closely resembles an intracranial space-occupying lesion. We here report 5 such cases

Case-reports

Case 1.—A painter's manager, aged 39, was first admitted to the National Hospital, Queen Square, on Dec. 9, 1954, under the care of Dr E. A Carmichael (N.H. 56282) Six months previously he had been admitted to another hospital because of major seizures, headache, and abdominal pain of recent onset. He was confused, but the only neurological signs were a right extensor plantar response and an equivocal one on the left. The cerebrospinal fluid (C.S.F) pressure was 120 mm. of water, the protein content 125 mg per 100 ml , and the cell content 2 lymphocytes per c.mm The electroencephalogram (E.E.G) showed an area of gross abnormality over the left hemisphere with depression of alpha activity over the post-central region. A parietal burr-hole failed to reveal any lesion, but the C.S.F. in the left lateral ventricle contained 500 mg of protein per 100 ml and 7 cells per c.mm The blood Wassermann reaction (W.R.) on one occasion only was weakly positive, and a course of intramuscular penicillin was given. He improved somewhat, but two months later a right subphrenic abscess was detected and drained, two months afterwards a discharging abdominal sinus was still present. Two weeks before admission to the National Hospital increasingly severe headaches returned, and four days before admission he had several generalised convulsions

Examination.—The patient was drowsy and there was evidence of considerable weight-loss Apart from bilateral papillœdema, more obvious on the left, the nervous system was normal A ventriculogram was normal, but films taken twenty-four hours later showed that the right lateral ventricle was slightly larger than the left. The E.E.G suggested a deep, central lesion.

Course—On Dec. 24, 1954, it was clear that the subphrenic abscess had returned, and he was transferred for surgical treatment He was readmitted five weeks later, having had periods of maniacal behaviour necessitating retention in an observation ward. Two days before his return, a right hemiplegia and aphasia appeared and were progressive. He had gradually become comatose. He had decerebrate rigidity with bilateral papillœdema, fixed dilated pupils, variable spasticity of the limbs, and bilateral extensor plantar responses Ventriculography showed a raised C.S.F pressure and ventricular displacement to the right, indicating a large left frontal space-occupying mass A left frontal burr-hole with needle biopsy yielded only necrotic brain tissue, and the patient died twenty-four hours later.

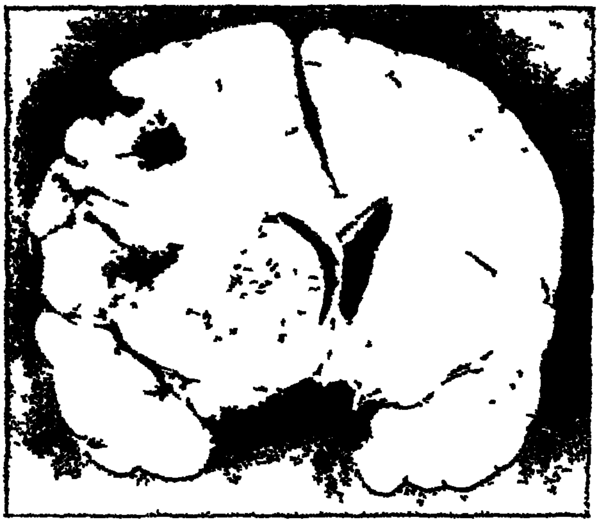

Fig 1—Case 1 brain section (viewed from behind), swollen left cerebral hemisphere.

Necropsy

The left internal carotid artery was completely blocked at its origin by an old organising clot, which, with the addition of a more recent clot, extended distally to the intracranial divisions of the vessel. At the bifurcation of the right common carotid artery an organising saddle-shaped clot was found, blocking the external but not the internal carotid artery

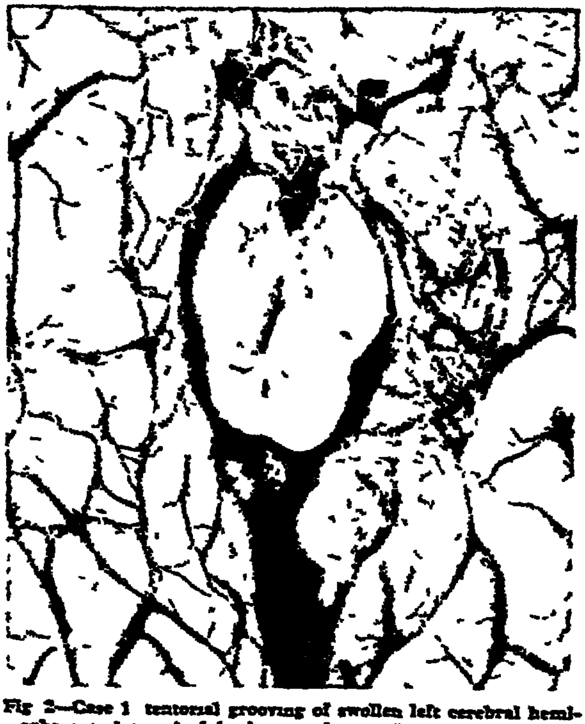

Fig 2—Case 1 tentorial grooving of swollen left cerebral hemisphere and terminal brain-stem hæmorrhage.

The vertebral arteries were normal

In the left cerebral hemisphere there was extensive pale and hæmorrhagic infarction in the distribution of the middle cerebral artery (fig 1) This hemisphere was greatly swollen, and there was evident uncal herniation (fig 2) The right cerebral hemisphere was normal

The left ventricle of the heart was moderately hypertrophied, and there was moderate atheroma of the aorta There were remnants of the subphrenic abscess

The whole clinical picture can be explained by progressive occlusion of the left internal carotid artery, terminating with complete obstruction and further infarction of the already affected left cerebral hemisphere The right external carotid artery no doubt shared in the terminal arterial obstruction, and this may have contributed to the death by compromising essential collateral channels The diagnosis of carotid occlusion, however, was made only at necropsy, and at all times a space-occupying lesion was thought to be present In view of the known focus of infection it was reasonable to postulate the presence of a cerebral abscess An angiogram, however, would have indicated the diagnosis

Case 2 —A watchman, aged 58, was admitted to the Royal Infirmary, Edinburgh, on Dec 14, 1953 A year previously he had had four "blackouts", being unconscious for ten to fifteen minutes in each For three months he had had severe intermittent left frontal headaches, and for a month weakness and numbness of the right hand and forearm, with some recovery For some months his memory had been poor and he was irritable Three times during a severe headache he had noted a haze over his left eye for about ten minutes A month before admission progressive right-sided hemiparesis developed, beginning in the face, and he became very lethargic

Examination —He was drowsy, and cooperation was limited (There was no dysphasia as he was left-handed) He had right spastic hemiparesis, right homonymous hemianopia, and bilateral papillœdema Pulsation of the carotid arteries in the neck and in the fauces appeared to be normal The blood-pressure was 135/90 mm Hg Radiographs of skull and chest were normal The C S F pressure was normal, and protein content 56 mg per 100 ml A left carotid angiogram on the day after admission showed complete occlusion of the internal carotid artery

Course —The patient became increasingly drowsy, evidence of severe brain-stem ischæmia appeared, and he died twenty-two hours after angiography

Necropsy (Dr A F J Maloney and Dr N Maclean)

There was thrombosis of the whole of the left internal carotid artery, and the clot extended into the left anterior and middle cerebral branches for about 1 5 cm The clot in the distal portion of the internal carotid artery was more recent than that situated proximally No cause for the thrombosis was found

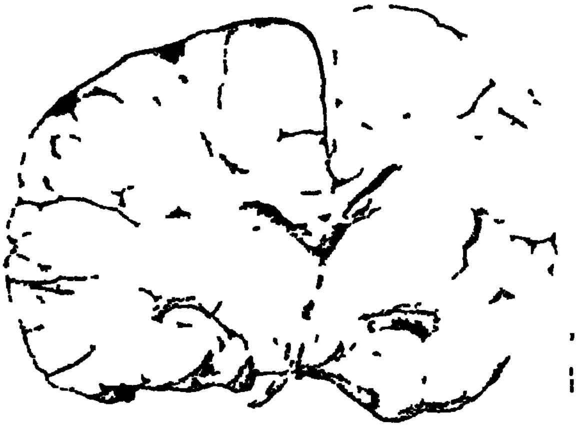

Fig 3—Case 2 brain section (viewed from behind) showing infarcted swollen left cerebral hemisphere

There was massive infarction of the left cerebral hemisphere in the territory of the middle cerebral artery, the age of the infarct varied in different parts from about two to twelve days The hemisphere was very swollen and there were secondary brain-stem hæmorrhages (fig 3)

Atheroma of the aorta and superior mesenteric artery, with old thrombosis of the latter vessel, were also found

The earlier features were thought to be due to cerebrovascular accidents, but the later picture of a progressive enlarging intracranial lesion suggested the presence of a rapidly growing neoplasm Progressive stenosis of the internal carotid artery would account for the initial symptoms, and there was complete obstruction of the lumen terminally

Case 3 —A man, aged 72, was admitted to the National Hospital, Queen Square, on July 30, 1954, under the care of Dr Michael Kremer (N H 53765) For two months he had noticed progressive difficulty in expressing his thoughts, and his wife found that he was becoming slow in his speech and did not always understand what was said to him Two weeks before admission the right foot began to drag, and the whole limb rapidly became weak

Examination —He had mild motor and sensory dysphasia The right leg was severely weak, but only slight clumsiness of the right arm could be detected Reflexes were increased in the right limbs, and the plantar response was extensor Sensation was normal Blood-pressure was 210/100 mm Hg, but the cardiovascular system was otherwise normal Radiographs of skull and chest were normal The C S F was normal The E E G showed a slow-wave focus in the left frontal region, thought to be consistent with a neoplasm A left carotid angiogram revealed obstruction of the internal carotid artery within a few millimetres of its origin, traces of dye in the ipsilateral carotid siphon suggested an anastomotic circulation An air encephalogram showed cerebral atrophy, more advanced on the left side

The picture here was of gradually progressive dysfunction of the left cerebral hemisphere, more suggestive of a neoplastic than of a vascular process, despite the patient's age and blood-pressure Efficient anastomotic channels probably prevented severe ischæmia

Case 4 —A housewife, aged 49, was admitted to the National Hospital, Queen Square, on Nov 11, 1954, under the care of Mr Wylie McKissock (N H 55679) For four months there had been obvious mental deterioration, which included memory impairment and personality changes In the preceding few weeks she had had two seizures, in one of which there were involuntary movements of the right limbs Progressive weakness of the right limbs and dysphasia then developed When she was investigated elsewhere, the only abnormality was a C S F protein of 200 mg per 100 ml

Examination —There was severe dysphasia, bilateral papillœdema, right hemianopia, and severe right hemiplegia and hemianæsthesia with corresponding reflex changes The cardiovascular system was normal Radiographs of the skull were normal The E E G showed extensive slow-wave activity arising from the left temporal region Ventriculography revealed a normal ventricular system A left carotid angiogram showed complete occlusion of the internal carotid artery at the level of the cavernous sinus

Course —The patient has remained severely incapacitated by dysphasia and a right hemiplegia

A provisional diagnosis of cerebral tumour seemed justifiable and ventriculography was carried out A carotid angiogram, however, indicated the lesion

Case 5 —A postmaster, aged 58, was admitted to the Royal Infirmary, Edinburgh, on Dec 3, 1954 Fifteen months previously he had had a cardiac infarction, and since then angina of effort Four months before admission severe left-sided headaches began, they eased after two months A right facial weakness of central origin appeared a month before admission, and two weeks later weakness and trembling of the right hand began. He also had episodes of severe, mainly expressive, dysphasia On the morning of admission he had become increasingly drowsy, and had Cheyne-Stokes respiration.

Examination —After intravenous infusion of hypertonic saline and sucrose solutions, he was not drowsy, but he had dysphasia (mainly expressive) and agraphia He had moderately severe right hemiparesis and hemianalgesia and complete right homonymous hemianopia The left pupil was dilated The cardiovascular system was clinically normal, except for a blood-pressure of 195 115 mm. Hg The C.S F was under normal pressure, and contained 21 cells (20 lymphocytes) per c.mm and 220 mg of protein per 100 ml The E.E.G was unsatisfactory owing to the patient's restlessness Left carotid angiography showed partial occlusion of the internal carotid artery at the level of the cavernous sinus, some dye had entered the basilar and posterior cerebral arteries

Course —The patient became increasingly drowsy and died five days after admission (sixty hours after angiography) with evidence of brain-stem ischæmia The lumbar C.S.F examined thirty-six hours before death was under a pressure of 160 mm water and contained 280 cells per c.mm (mainly lymphocytes), and 142 mg of protein per 100 ml

Necropsy (Dr A F J Maloney)

There were extensive severe endarteritis and periarteritis of the internal carotid arteries and of most of their branches, and of the basilar artery There was thrombosis of the termination of the left internal carotid artery, with occlusion of the anterior and middle cerebral branches

There was a recent massive infarction of the brain in the distribution of the left anterior and middle cerebral arteries, and there were terminal secondary brain-stem hæmorrhages In addition, generalised atheroma was seen, with severe involvement of the coronary arteries and aorta

The progressive nature of the illness suggested an intracranial space-occupying lesion, but the episodic features, the previous history of a cardiac infarction, and the hypertension indicated the possibility of cerebrovascular disease The internal carotid artery became completely obstructed only terminally The nature of the endarteritis was not determined

Discussion

The clinical spectrum of thrombosis of the internal carotid artery is wide, ranging from almost complete absence of symptoms, as in the patient of Willis (1664), who enjoyed " the free exercise of his mind and his animal functions ", to a rapidly fatal illness of apoplectic onset Between these extremes are found most cases

It is possible to delineate distinct clinical groups, and in the one discussed here there is a slowly progressive course simulating that of an intracranial space-occupying lesion

In Johnson and Walker's (1951) series these cases formed the second group, whereas Behrman (1954), recognising four groups, placed them in his fourth Törma and Troupp (1957) described acute, subacute, and chronic cases, and among the chronic cases were those masquerading as cerebral tumours Paillas and Christophe (1955), using the same grouping, gave the name "pseudo-tumoral" to cases in which the course was slow and progressive. Whereas Smyth (1956) thought that they formed only a very small percentage of all cases, Johnson and Walker (1951) estimated the proportion at 25% At the moment, however, there is insufficient information to indicate an incidence accurately

Thrombosis of the internal carotid artery has not uncommonly been discovered by cerebral angiography carried out in the investigation of suspected intracranial tumour (Moniz et al 1937, case 2, Riechert 1938, case 3, Sorgo 1939) There are many reports of individual cases and the patient of King (1951) is very similar to ours Wood and Farmer (1957) have reported 5 cases of cerebral softening simulating brain tumour, in 3 of which obstruction of the internal carotid artery was the cause

Pathology

The pathological processes responsible for the progressive downhill clinical course and the features of intracranial hypertension are on the whole easy to understand

The first symptoms are produced by gradual encroachment on the lumen of the internal carotid artery, resulting in the syndrome of intermittent carotid insufficiency described by Denny-Brown (1951) and others This explanation, which can also be applied to occlusive disease of other cerebral arteries (Corday et al 1953) accounts for the clinical events better than " vasospasm " or multiple emboli, though these mechanisms cannot at the moment be excluded entirely Initially the transient ischæmia does no permanent damage to the brain, but an area of infarction is eventually produced, and, as in our fatal cases (cases 1, 2, and 5), there is massive softening terminally owing to complete obstruction of the already constricted artery

When infarction of brain tissue takes place, there is swelling of the affected part, and this can be seen in cases of softening due to occlusion of intracranial arteries (Sorgo 1939, Smiley 1952, Farmer and Swanton 1955, Scarcella 1956, Wood and Farmer 1957) When it results from obstruction of the internal carotid artery in the neck or at the base of the skull, the extent of the lesion is determined by the efficiency of the collateral channels and by the distribution of arteriosclerosis, which is usually the basic arterial disease In cases 1, 2, and 5 (figs 1 and 3) there was severe swelling of the affected cerebral hemisphere, the cases of Raney (1948), King (1951), Paillas and Christophe (1955), and Berry and Alpers (1957) were similar Death is due to ischæmia and hæmorrhagic destruction of the brain-stem (fig 2) exactly comparable to that with a supratentorial cerebral neoplasm, and due to displacement of intracranial structures by an expanding mass of infarcted brain tissue (fig 2) Thus the picture—of intermittent focal brain ischæmia, followed later by infarction, and, after complete carotid obstruction, by extension of the cerebral lesion, which behaves in all respects like a growing tumour—may be indistinguishable from that of a space-consuming lesion

Clinical Findings

There are often two stages in the development of the picture firstly the progressive or intermittent appearance of focal symptoms, and secondly the features of a space-occupying cerebral lesion which usually necessitate admission to hospital The usual history is one lasting weeks or even years, characterised firstly by persistent headache, which is also a common feature in other types of carotid thrombosis, but as in case 4 headache may be absent. Focal or generalised convulsions, and progressive weakness and paræsthesiæ of the limbs on one side, mainly in the arm, now appear, often in this order, and if the dominant hemisphere is involved dysphasia will be added The defects of speech and limbs may appear in attacks with complete recovery between them, and these episodes, which presumably result from transient cerebral ischæmia, may closely simulate focal epileptic attacks Eventually permanent signs appear There is also impairment of mental state, and this too may be progressive or intermittent and may be related to disturbance of language function when the dominant hemisphere is involved

On examination in the second clinical phase, all the signs of a cerebral tumour may be discovered The patient may be drowsy and papillœdema is often present As in cases 1, 2, and 4, the papillœdema may be bilateral and at times greater on the side of the affected cerebral hemisphere (case 1), as much as 3 dioptres have been observed (Riechert 1938, case 3, Poppen and Baird 1952) Unilateral swelling of the disc, on the involved side, has been described, but in some of these cases the swelling has been an early sign of occlusion of the central retinal artery (Feiring 1954, Lamont and Brink 1956) In view of the occasional appearance of ipsilateral optic atrophy with carotid-artery thrombosis the Foster-Kennedy syndrome would be possible, but it has not been described (Fisher 1952) The signs elsewhere in the central nervous system indicate extensive cerebral damage Clearly such cases as these may closely mimic an intracranial expanding lesion, and further investigation may emphasise the similarity

Investigations

Skull radiography—If an infarcted area of brain is large enough a pineal shift may be seen (King 1951, Jefferson 1955, Droni et al 1957), but this is rare Jefferson (1955) has pointed out that radiological evidence of sellar erosion, identical with that produced by intracranial hypertension due to a tumour, can arise in patients with raised blood-pressure As internal carotid thrombosis often occurs in the presence of hypertension a further similarity is possible

Cerebrospinal fluid—Its pressure may be raised (Sastrasin 1957, case 1), but little is known of the lumbar fluid as lumbar punctures are rarely carried out in the presence of papillœdema As in our cases, the protein content and cell count of the lumbar and the ventricular C S F are often increased, because of the large area of destroyed brain tissue

Electroencephalography—Abnormalities are commoner than with other types of cerebrovascular disease (Feiring 1954), and, as in our cases, there is often a focus of abnormal electrical activity which may be mistaken for that produced by a cerebral tumour or abscess, but differentiation is usually possible if serial recordings are made Paillas and Christophe (1955) have discussed the E E G changes in detail

Air studies may indicate the presence of an intracranial mass (Elvidge and Werner 1951, Torma and Troupp 1957, case 1), but more often they are normal or show a dilated ventricle on the side of the diseased artery with a ventricular shift toward that side, indicating cerebral atrophy resulting from chronic ischæmia of the hemisphere (Johnson and Walker 1951)

Types of Space-occupying Lesion

In differential diagnosis three types of intracranial space-taking lesion must be considered cerebral neoplasm, cerebral abscess, and traumatic intracranial hæmorrhage

The confusion between internal carotid artery thrombosis and primary cerebral neoplasm during the early days of carotid angiography has already been mentioned and in addition Paillas and Christophe (1955) point out the possibility of the arterial lesion mimicking a secondary brain tumour Most authors have mentioned this diagnostic difficulty, and our cases 2–5 are examples of it

The findings most commonly simulate a malignant glioma

Carotid thrombosis may complicate an injury to the neck or head With the latter, all the manifestations of cerebral compression can be produced, and extradural, subdural, or intracerebral hæmorrhage is invariably diagnosed (Sedzimir 1955) Non-penetrating trauma of the carotid vessels may also result in drowsiness and hemiplegia, which always follow a "lucid interval" As there is often an associated head injury, or even if there is not, a diagnosis of extradural hæmatoma is not unnaturally made, whereas the responsible lesion may be thrombosis of the internal carotid artery (Schneider and Lemmen 1952, Murray 1957) Similar events may result from penetrating carotid injury (Caldwell and Hadden 1948), and case 5 of Raney (1948) offers a good example of how infarction of brain tissue due to acute internal carotid obstruction may have all the characteristics of an intracerebral expanding mass

Diagnosis

If treatment is to be effective internal carotid artery thrombosis must be diagnosed as early as possible, and certainly before complete arterial occlusion, which may produce irreversible cerebral destruction and often death Differentiation of the spontaneous type of carotid thrombosis from a cerebral neoplasm or abscess may be difficult and the two can be indistinguishable even in the presence of vascular disease elsewhere (cases 3 and 5) Palpation of the artery in the neck or tonsillar fossa is generally agreed to be of little value, and the only infallible test is carotid angiography But this is not without its risks, especially in these patients, and some have died (King 1951, Wilson 1955), the angiogram may have contributed to the deaths in our cases 2 and 5 Furthermore, Diethelm and Dontenwill (1953) have reported carotid thrombosis following angiography It is, however, possible that a less irritating radioopaque material, such as 'Thorotrast', would be justified in these cases It seems that a more innocuous investigation should be tried first Milletti (1950), Heyman et al (1957), and others recommend the estimation of retinal-artery pressures, and Fisher (1957) has reported that a bruit heard over the healthy carotid artery is of diagnostic value It has often been observed that compression of the uninvolved internal carotid artery may produce syncope (Paillas and Bonnal 1952, Shapiro 1952, case 3), and Paillas and Christophe (1955) recommend that an E E G should be made at the same time, but personal experience (P H) indicates that the test is not invariably reliable Symptoms on the unaffected side of the body may also follow compression of the healthy artery, and Parkinson (1957) has indicated the value of this test in the differentiation of carotid thrombosis from cerebral tumour An application of the technique of Meyer et al (1956), who found E E G changes in the presence of insufficiency of carotid blood-flow and a fall of blood-pressure, may also be useful Direct inspection of the vessel may, however, be necessary, and at times angiography cannot be avoided

A further diagnostic possibility of the greatest importance is occlusion of the internal carotid artery in the presence of an intracranial space-occupying lesion Thus Pauly (1954) describes a patient with the clinical appearances of a cerebral neoplasm who was shown by angiography to have complete occlusion of the ipsilateral internal carotid artery in the neck The angiogram was repeated and the vessel was now patent, indicating presumably that the initial findings were due to arterial spasm, this patient had a frontoparietal glioma Similar cases are reported by Erikson (1943) and Krayenbuhl and Weber (1944, case 19), and Gros (1955) mentions spasm of the internal carotid artery associated with a cerebral abscess Thus the angiographic demonstration of an obstructed artery in a patient with symptoms and signs of a cerebral tumour does not necessarily invalidate the diagnosis of a neoplastic or infective process in the brain The appearances of the angiographic block often permit differentiation, but further angiography (preferably by direct exposure of the artery) or air studies will be necessary in these difficult cases

Another possibility is slowly progressive internal carotid thrombosis as a complication of malignant hypertension, for symptoms and signs of high intracranial pressure together with focal neurological abnormalities would be expected Clarke and Murphy (1956) did not find an example among 190 patients with hypertension and papillœdema, but not all the necropsies included inspection of the carotid arteries in the neck

Treatment

The mortality and morbidity of internal carotid artery thrombosis are high Sastrasin (1957) estimates the mortality at 34%, of the survivors of his 65 patients, more than half had a severe neurological deficit Our approach to treatment must therefore be as active and as early as possible Nevertheless, the prognosis in many cases is determined not by the lesion of the internal carotid artery alone but also by the basic defects of arteriosclerosis and inadequate collateral channels

If possible, treatment should be carried out before complete arterial occlusion takes place, but this is only occasionally feasible, Edwards and Rob (1956) report the successful surgical handling of a stenosed artery Medical measures, such as antispasmodic and anticoagulant drugs, have not been very effective in the chronic or the acute phases of the disease, and anticoagulants are thought by some to be contraindicated in view of possible hæmorrhagic complications in the brain A surgical approach seems to be more profitable (Rob and Wheeler 1957), and Strully et al (1953) have described a patient who was at first thought to have a cerebral neoplasm but who was shown by angiography to have thrombotic occlusion of the internal carotid artery, and in whom thromboendarterectomy was successful

In the acute phase of complete arterial occlusion, therapy has unfortunately been unavailing To counter the swelling of the brain produced by infarction, bilateral subtemporal decompression has been carried out without success (Schneider and Lemmen 1952, case 2), and other measures to reduce intracranial tension have also failed to prevent death Hypothermia, as used with other cerebrovascular conditions (Lougheed et al 1955, Burrows et al 1956, Bohm et al 1957), may be more valuable, and together with the advance of arterial surgery may some day reduce the mortality and morbidity of this disease

The importance of considering thrombosis of the internal carotid artery when dealing with a patient manifesting the features of an intracranial space-occupying lesion is obvious, and the earlier the diagnosis can be made the more effective is treatment likely to be

Summary

Among the many clinical pictures produced by occlusion of the internal carotid artery is that of an intracranial space-occupying lesion

5 illustrative cases are reported, in 4 cerebral neoplasm had been diagnosed, and in 1 cerebral abscess

The early symptoms are due to carotid-artery insufficiency, and the syndrome of intracranial hypertension is produced by the area of brain softening and surrounding œdema which appear eventually

Symptoms and signs, as well as radiographic, C S F, and E E G abnormalities, may be identical with those due to a space-occupying lesion, and certain differentiation can be made only by carotid angiography

An incorrect diagnosis of cerebral neoplasm, cerebral abscess, or traumatic intracranial hæmorrhage may be made in the presence of carotid-artery occlusion

Treatment, to be effective, must be early, operation on the artery seems to be the only hopeful possibility

We have great pleasure in thanking Prof Norman Dott and the medical committee of the National Hospital, Queen Square, for kindly allowing us to publish the clinical and pathological material

EFFECT OF CERTAIN DIETARY OILS ON BILE-ACID SECRETION AND SERUM-CHOLESTEROL

BARRY LEWIS
M B, Ph D Cape Town, A R I C

With the technical assistance of ENID VOLKS, B Sc Cape Town

From the Clinical Nutrition Unit of the Council for Scientific and Industrial Research and the Department of Medicine, University of Cape Town

THE serum-cholesterol level is raised by most fats of animal origin, but is lowered by many highly unsaturated oils from vegetable and marine animal sources (Frishley et al 1955, Ahrens et al 1955, Bronte-Stewart et al 1956) The object of the present study was to identify the mechanism or mechanisms by which these unsaturated oils lower the serum-cholesterol Gordon et al (1957a, 1957b) showed that the feeding of sunflower-seed oil increased the excretion of bile acids in the fæces—to an extent that would fully account for the cholesterol leaving the circulation Hellman et al (1957), using ^{14}C-labelled cholesterol, have shown increased fæcal elimination of the radioactive material on feeding corn oil There is little doubt (Siperstein et al 1952, Bergstrom and Norman 1953, Siperstein and Chaikoff 1955, Siperstein and Murray 1955) that cholesterol is excreted mainly as bile acid, both in the rat (taurocholic acid), and man (glycocholic acid) In the experiments to be described, three patients with complete bile fistulæ were studied, the bile-acid output being followed during manipulation of the serum-cholesterol by administration of various fats and oils

Methods

The clinical features are summarised in table I No patient had clinical or biochemical evidence of disturbed liver function, nor was there overt infection of the biliary tract

On and after the third postoperative day, they received a basal diet yielding 2000 calories and containing 75 g protein and 5 g fat The common bile duct was drained through a T-tube, this was indicated after exploration of the duct, and in case 2 the dilated sphincter of Oddi was splinted by a long-limbed T-tube Wangensteen drainage was used in cases 1 and 2 but was probably unnecessary, for collection by siphonage in case 3 was entirely adequate The postoperative course of the patients was satisfactory, and no deleterious effects resulted from this regime The fistulæ were thought to be virtually complete, because little or no bile acid was detected in the fæces, and the stools were pale Blood was drawn at intervals of about 48 hours, at 9 A M Fat absorption, as expected, was impaired by the existence of bile fistulæ, absorption was 80–90% during fat feeding , In animals with bile fistula, 65–75% of fat is absorbed (Pessoa et al 1953)

Bile was collected in 24-hour batches, with thymol as a preservative, it was stored at −15°C and worked on within 4 days Aliquots of 1 ml were saponified in sealed ampoules at 120°C for 4 hours, by means of 2 ml of 2 *N* sodium hydroxide The unsaponifiable fraction was extracted with petroleum ether (40–60°C boiling *point) and the cholesterol content determined by the Liebermann* Burchard reaction The aqueous phase was then acidified, congo red was used as the indicator Fatty acids were removed by petroleum ether extraction, and bile acids extracted with four 4-volum quantities of ether, the ether extract was washed with 0 2 volumes of water, then taken to dryness In this form it was stored at −15°C until analysis was completed Bile acids were identified and determined by Mirvish's (1958) quantitative modification of the reversed phase column-chromatographic procedure of Sjövall (1953) In this laboratory the overall procedure has given 85–97 5% recoveries of cholic acid and 82–100 2% recoveries of deoxycholic acid The chromatographic system does not resolve deoxycholic from chenodeoxycholic acid

CLINICAL FEATURES OF THE THREE PATIENTS

Case	Age	Sex	Race	Operation	Interval between operation and first basal observation
1	30	F	African	Cholecystectomy and choledochotomy for stone in common duct	5 days
2	36	M	European	Sphincterotomy for relapsing pancreatitis	8 days
3	68	M	Coloured	Cholecystectomy and choledochotomy for stone in common duct	5 days

Serum-cholesterol was determined by the method of Abell et al (1952) as modified by Anderson and Keys (1956) The procedure of van de Kamer et al (1949) was used in measurements of fæcal fat

Sunflower-seed oil, of refined grade, was used from a single batch, the iodine value was 135, and the Liebermann-Burchard chromogen in the unsaponifiable fraction was equivalent to 751 mg cholesterol per 100 ml Coconut oil was hydrogenated

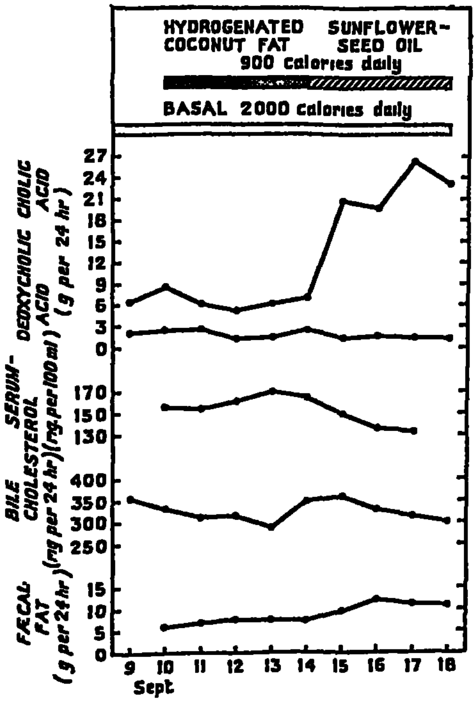

Fig 1—Case 1 Response to hydrogenated coconut fat followed by sunflower-seed oil

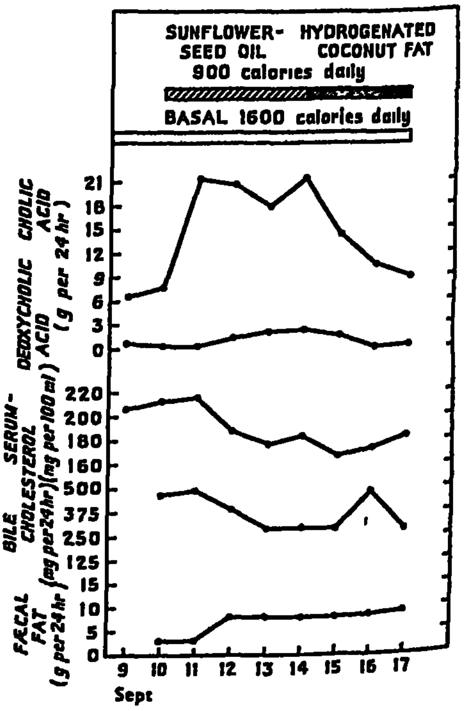

Fig 2—Case 2 Response to sunflower-seed oil followed by hydrogenated coconut fat

to an iodine value of 6, and contained 303 mg per 100 ml of similarly measured sterol The oils were administered uncooked, in divided doses A preparation of cotton-seed oil for intravenous use ('Lipomul', Upjohn), emulsified with 'Pluronic F68' and soybean phosphatide, was also used This oil had an iodine value of 115 On intravenous administration the emulsion lowers the serum-cholesterol (H Gordon, unpublished observations)—a property not shared by a comparable oil-free solution containing the emulsifying agent. Unfortunately no similar preparation of a saturated fat was available

Results

Case 1—Hydrogenated coconut oil did not raise the serum-cholesterol level, and had no effect on the composition of the bile. Sunflower-seed oil given for 4 days lowered the serum-cholesterol significantly and produced a fourfold increase in the cholic-acid secretion Deoxycholic-acid and bile-cholesterol output did not vary consistently The fæces were virtually bile-free. The increase in cholic-acid secretion began on the day the oil was introduced, and thus preceded the fall in serum-cholesterol (fig 1)

Case 2—The order in which the oils were administered was reversed in this experiment, the response was essentially similar (fig 2), except for a moderate rise in the deoxycholic-acid (— chenodeoxycholic-acid) peak When sunflower-seed oil was replaced by hydrogenated coconut oil, the cholic-acid secretion fell steeply but did not reach the basal level in 3 days

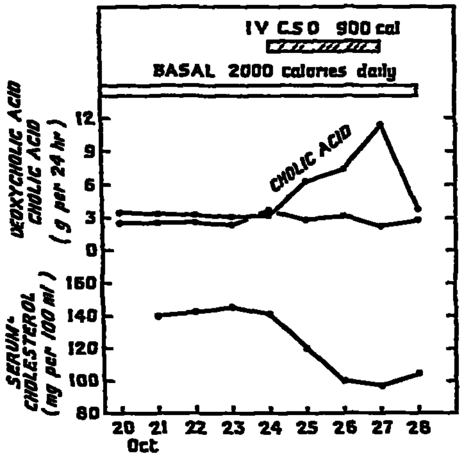

Fig 3—Case 3. Response to infusion of cotton-seed oil (I V C.S O)

Case 3—Intravenous infusion of cotton-seed oil was at least as effective as oral sunflower-seed oil in lowering the serum-cholesterol, cholic-acid output was increased (fig 3)

Discussion

This investigation was based entirely on transient-state observations, being concerned with the phenomena associated with a *changing* serum-cholesterol The establishment of bile fistulæ increases bile-acid synthesis in rats (Eriksson 1957), a plateau being reached in 3–4 days The present experiments were internally controlled and the basal observations began not less than 5 days after operation. Diet-induced fluctuations in the serum-cholesterol could theoretically be due to variations in its rate of synthesis, absorption, deposition, excretion, or catabolism, in the process of cholesterol "trapping" (Byers and Friedman 1955), or in more than one such mechanism An earlier communication (Gordon et al. 1956) described our failure to demonstrate significant changes in fæcal Liebermann-Burchard-reacting sterols during manipulation of the serum-cholesterol by dietary means, and our demonstration of increased fæcal bile-acid excretion during feeding of sunflower seed oil Fluctuations in fæcal sterol excretion, in fact, correlated best in that study with the dry weight of fæces, and were conditioned by the dietary phytosterol content.

Ingestion of unsaturated oils does not suppress cholesterol absorption (Karvinen et al. 1954) Nor does it reduce cholesterol synthesis; evidence from in-vitro studies using labelled substrates is to the contrary (Merrill 1958) In the light of the present experiments as well as by exclusion, the hypothesis is submitted that certain vegetable oils (administered orally or intravenously) reduce the serum-cholesterol by a mechanism which involves accelerated catabolism of cholesterol to cholic acid. Siperstein et al. (1952) and Siperstein and Murray (1955) were able to recover 95% of the radioactivity of labelled cholesterol from the fæces, of which over 80% was in the bile-acid fraction, the remainder in neutral material.

Conversely, the elevation of serum-cholesterol levels by hydrogenated coconut fat was not associated with reduction of bile-acid output, measured directly in two people with fistulæ or indirectly in the fæces of six normal ones (Gordon et al. 1957a, 1957b), though Salomon (1926) described a rise in bile-cholesterol on feeding butter This is somewhat at variance with the results of Hellman et al. (1957) in a patient with hypercholesterolæmia Using cholesterol-4-^{14}C, they found that butter oil increased the serum-cholesterol and reduced the fæcal excretion of "cholesterol and its end products", corn oil had the reverse effects These workers inferred an intestinal excretory mechanism for the regulation of the serum-cholesterol Kinsell et al (1958) were unable to detect reciprocal changes in the serum-cholesterol and the fæcal-sterol excretion on feeding a variety of preparations containing unsaturated fatty acids The findings in the present study favour a catabolic mechanism for the action of some oils in lowering the serum-cholesterol, but point to an unrelated mode of action for hydrogenated coconut oil in elevating the level of this sterol It is widely held that saturated fats increase the synthesis of cholesterol from acetyl coenzyme A, which arises from β-oxidation of fatty acids Fasting depresses cholesterol synthesis (van Bruggen et al 1952), and feeding of fat increases the rate of incorporation of ^{14}C-labelled acetate into cholesterol, simultaneously decreasing its conversion to glycogen and fatty acid (Whitney and Roberts 1955)

Quantitative considerations indicate that far more bile acid is produced during oil feeding than is necessary to account for the disappearance of cholesterol from the circulation. The inference is either that cholesterol is being mobilised from the tissues, or (more probably) that cholesterol synthesis is increased during administration of oil Increased synthesis from acetate has been demonstrated in liver slices from animals previously fed on cotton-seed oil (Whitney and Roberts 1955) An analogy may be drawn with hyperthyroidism, where there is a tendency to a low serum-cholesterol despite increased cholesterol synthesis (Kurland and Lucas 1955) Weiss and Marx (1955) have shown in animal experiments that thyroid hormone stimulates the degradation of cholesterol to acid derivatives

Summary

Bile-acid excretion has been studied during the administration of various types of fat, to three patients with complete bile fistulæ

Sunflower-seed oil (by mouth) and cotton-seed oil (intravenously), which are both highly unsaturated, produced a remarkable increase in the rate of cholic-

acid secretion, which preceded the fall in serum-cholesterol On the other hand, a saturated fat (hydrogenated coconut oil), did not affect the bile-acid output but raised the serum-cholesterol These findings support the hypothesis that the mechanism by which the serum-cholesterol is reduced by certain vegetable oils involves accelerated catabolism of cholesterol to cholic acid

Sincere thanks are due to Dr S Mirvish for allowing access to his analytical method before its publication, to Prof J F Brock and Prof L Eales for helpful criticism and encouragement, and to Prof J Louw, Mr D J du Plessis, and Mr G Sacks for making patients available for these studies Messrs Merck & Co provided samples of bile acids

This study was undertaken as part of the programme of the Clinical Nutrition Research Unit, supported in the University of Cape Town by the South African Council for Scientific and Industrial Research

HYPOTHERMIA BY INTERNAL COOLING IN MAN

H H Khalil
M B Alexandria, Ph D Lond
LECTURER IN MEDICINE, UNIVERSITY OF ALEXANDRIA, EGYPT

In 1954 a new method of lowering or raising body temperature in animals and man by introducing cold or warm water inside an intragastric bag was described (Khalil and Mac Keith 1954) In September, 1956, at the second European Congress of Cardiology, a series of experiments was reported where deep hypothermia in dogs was induced by a continuous flow of cold water through an intragastric water balloon, and the term " internal cooling " was suggested for this new and simple method

In the two cases at Alexandria University Hospital reported here, this method was used in neurosurgery in man The apparatus used was the same as that which I have been using for dogs, modified to make it more compact, easier to manage, and generally more suitable for a hospital operating-theatre

Apparatus

The apparatus (fig 1) consists of a water tank N, of 10 litres capacity, which can be either cooled by means of a cooling coil D attached to a compressor, or warmed by means of an electric resistance coil P Both coils are immersed in the water inside the tank The temperature of the water is controlled by means of two thermostats—R for cooling and R_1 for warming The water tank is surrounded by a thick cork jacket which provides temperature insulation

A suction water-pump F sucks the water from the intragastric balloon into the water tank N, and, since the tank is hermetically sealed, automatically drives an exactly equal volume of water to the balloon In this way, the volume of the balloon remains constant Two air-traps G and K are included in the circuit—one G just before the suction-pump and the other K between the tank and the balloon—to prevent air from entering the balloon or the pump

A graduated 5-litre jar H, with an attached sphygmomanometer pump and a bottom tap T, lies above the tank It is connected to the tank by a T-piece Tap T is opened only while filling or emptying the balloon A (Palmer) flow-meter C is also included in the circuit, between the balloon and the pump The screw-clamps S and S_1 are applied to the thick rubber tubing leading to and from the balloon They are used to clamp the rubber tubing while the empty balloon is being introduced into the stomach, to prevent water from leaking into it at that time A special metal junction M is designed to allow to-and-fro currents through the tubes A and B leading to and from the intragastric balloon, the tubes being made of 'Porges Neoplex', 1 0 metre long The outer tube should be 1·0 cm in diameter and the inner one 0 6 cm The intragastric balloon itself is an ordinary condom—preferably two, one inside the other, in case one should accidentally leak A thermometer is immersed into the air-trap K to register the temperature of the inflowing water The whole apparatus is fitted inside a suitable stand with wheels to allow rapid transport

Operation of the Machine

The tank and all the tubing and air-traps are filled with water from jar H The intragastric water balloon is then tested by distension with water, which is done by applying pressure in the jar H through the sphygmomanometer pump The balloon is then emptied by switching on the suction water-pump and clamping the rubber tube at S_1 The suction-tube is then also clamped at S, and the tap T closed and the pressure in jar H released After insertion of an intratracheal tube, the balloon is introduced into the stomach through the mouth It goes with ease

When the intragastric balloon is in situ, both clamps (S and S_1) and tap (T) are opened and pressure applied in jar H to fill the balloon to the required volume as shown by the graduations on the jar When the balloon is full, the stomach should be palpated through the anterior abdominal wall to see that it is not unduly tense Tap T is then closed and the pump switched on Any air still remaining in the circuit will immediately be trapped in jars G and K as the water circulates The thermostat of the water-cooler unit is adjusted to the range between 5° and 7°C and the rheostat of the pump so adjusted that about 10 gallons (45 5 litres) of water passes per hour, as indicated by the flow-meter In this way 0 75 litre of cold or warm water will circulate through the balloon per minute The intragastric balloon should never be filled with more than 1 5 litres of water The arrangement by which the balloon receives only a volume of fresh water equal to what has been withdrawn will keep the volume of the balloon constant throughout the cooling or rewarming procedures, without any risk of overdistending the stomach

If the rate of cooling the body is more rapid than is desired, the volume of the balloon is reduced by clamping the rubber tube at S and opening tap T, the water will then be diverted to the jar instead of returning to the balloon When the required volume is reached, tap T is closed and clamp S_1 is released The same procedure should be repeated whenever the volume of the bag should be changed as judged by the rate of cooling or rewarming the body

When rewarming is indicated, the warming unit with its thermostat is switched on instead of the water cooler The circulating water will then be gradually warmed according to the adjustable thermostat, but its temperature should not rise more than 10 C above the rectal temperature, and should never exceed 40°C

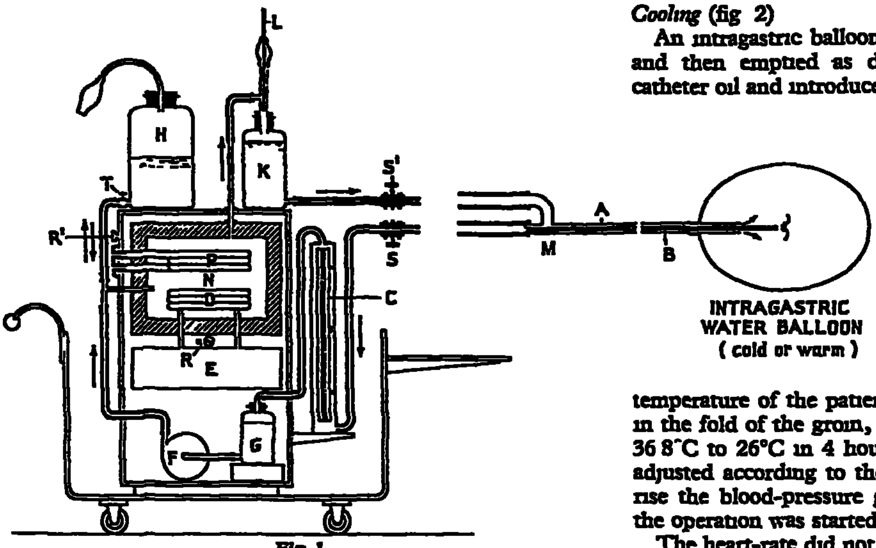

Fig 1

Case-reports

Case 1 —An adult was admitted to the neurosurgical unit, Alexandria University Hospital, with a large swelling on the vault of the skull and signs of bilateral pyramidal-tract involvement The symptoms had started three years previously and had been progressive Arteriography revealed a large parasagittal meningioma of the size of an orange

The operation was performed by Dr B Vlahovitch and Dr S Boctor Anæsthesia was conducted by Dr H Nassar and Dr W Narshy

Premedication

The patient was prepared with chlorpromazine 25 mg and promethazine 50 mg at 2 A M , this was repeated at 6 A M 1 mg atropine was given at 8 A M Anæsthesia was induced with sodium thiopentone. An endotracheal tube was introduced and its cuff inflated Anæsthesia was maintained by nitrous oxide and oxygen

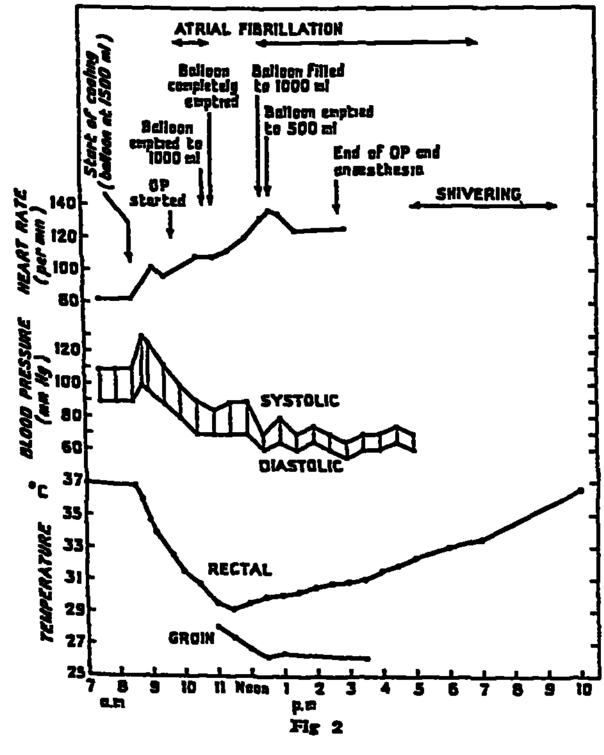

Fig 2

Cooling (fig 2)

An intragastric balloon, which had been tested beforehand and then emptied as described above, was smeared with catheter oil and introduced with ease into the stomach About 1 5 litres of water was pumped into the balloon from jar H, which was then isolated by closing tap T The stomach could be felt easily through the abdominal wall and was not unduly tense The patient was then put in the semi-sitting position for the operation Cooling was started at 8 30 A M by switching on the pump and the cooling compressor The temperature of the circulating water dropped to 5°C in 10 minutes The temperature of the patient was recorded both by rectum and in the fold of the groin, the groin temperature dropped from 36 8°C to 26°C in 4 hours (fig 2) The rate of cooling was adjusted according to the surgeon's request After an initial rise the blood-pressure gradually declined, beginning before the operation was started

The heart-rate did not undergo a corresponding drop This was probably because of the chlorpromazine and atropine premedication, in addition to the rather large blood-loss during the removal of the angiomatous tumour Atrial fibrillation began at 10 A M , when the rectal temperature was 31 5°C, and disappeared when cooling was stopped and the bag emptied at 11 A.M It recurred at 12 30 P M and remained till 7 P M , the rectal temperature then being 33 5°C This may have been another cause for the tachycardia

Operation

The operation was started when the rectal temperature was 32 2°C, 75 minutes after the start of hypothermia, it took 5 hours, ending at 2 45 P M During the latter half of the operation, cooling was started again by filling the balloon with 1 0 litre of circulating water for 10 minutes, and then maintained at a slower rate by keeping only 0 5 litre circulating This was done on the surgeon's request to retard spontaneous rewarming Otherwise, rewarming was left to take place spontaneously Anæsthesia was stopped as soon as the operation was completed The patient became responsive soon afterwards, and began to talk within an hour of the end of the operation During the rewarming period mild shivering began when the rectal temperature reached 32°C and continued until it reached 36°C

Postoperative Course

This was uneventful Next morning there was no epigastric tenderness, even on deep palpation and pressure The patient asked for food at lunch-time but was given fluids only, including milk. There was no vomiting Solid food was started on the third day

From the clinical point of view the result was very satisfactory The patient regained considerable motor power in his affected limbs within the next few days

Case 2 —A man, aged 42, was admitted to hospital with severe frontal headache, mental changes, and blurring of vision. On examination there was primary optic atrophy on the left side and severe papillœdema on the right side (Foster Kennedy's syndrome) Arteriography showed distinct shift of the left anterior cerebral artery to the right, suggesting a tumour of the left frontal lobe

Operation

This was carried out after induction of hypothermia to 32°C, by the same technique as in case 1 There was no arrhythmia, and the heart-rate dropped from 110 to 70 A left frontotemporal flap was turned The lateral ventricle was tapped to diminish the increased tension Localised frontal lobectomy was carried out exposing a dark reddish tumour that extended posteriorly under the anterior horn of the left lateral ventricle and around the left optic nerve and tract reaching the hypothalamic area The major part of the tumour was removed, leaving only the deep infiltrating part in relation of the internal capsule

Postoperative Course

The patient did well, and 5 days after the operation he was on full diet Clinically the result was satisfactory

Discussion

The advantages of internal cooling, compared with surface cooling or extracorporeal blood cooling, have been discussed elsewhere (Khalil and Mac Keith 1954, Khalil 1957a, b)

An apparatus for application of internal cooling has been described (Barnard 1956), but the apparatus described here has several advantages

Instead of pumping water into the stomach, the pump sucks the water from the balloon to the tank, the same volume of fresh cold water automatically passing from the water tank to the balloon It is impossible to overfill the stomach

The volume of the balloon can be adjusted at any moment to the required volume with greater ease

A flow-meter is included in the circuit By this means the rate of flow of water through the balloon can be controlled This is particularly useful in the shift from cold to warm water, when the rate of flow should at first be slow in order not to damage the gastric mucosa

Air-traps are included in the apparatus This is considered essential for the smooth performance of the pump and to prevent air from getting to the balloon

The action of the apparatus can be changed from cooling to rewarming at any moment Accordingly

(*a*) If, during the induction, serious cardiac arrhythmias appear, change to rewarming is possible

(*b*) After the operation is completed, the patient can be rewarmed to 35–36°C, the blood-pressure will then rise, and any bleeding-points can be noted and ligated before the field of operation is closed

(*c*) In cardiac operations the surgeon can perform the critical part of operation after rewarming has been begun by internal warming The myocardium will then be colder than the blood supplying it, and will presumably get the oxygen it demands more easily than during the cooling period (Barcroft and King 1910) The heart-muscle will then probably be less irritable to touch and other surgical insults than it is where the heart is hypothermic from other techniques Work is in progress in dogs to test the advantage of this procedure

Hypothermia by internal cooling presents advantages, and it is hoped that the simplicity and safety of this method will lead to its being tried in other indications for hypothermia Construction of the machine described here should be within the capacity of any good firm of engineers

Summary

An apparatus for giving a continuous flow of cold or warm water through an intragastric balloon is described

Two cases in which intracranial tumours were removed surgically under hypothermia by internal cooling are reported The first patient was cooled to a rectal temperature of 29°C and the second to 32°C

The method proved simple, easy to manage, and very effective—so much so that it was necessary to keep the intragastric balloon only half-filled to avoid too rapid cooling Both patients had an uneventful postoperative course

This method could be used in major neurosurgical and cardiac operations and in other indications for hypothermia

I thank Prof M L Dowidar, head of the department of surgery, Dr B Vlahovitch, and Dr S Boctor for permission and facilities to conduct this work in the department of surgery, Alexandria University, Dr H Nassar and Dr W Narsby for their help and cooperation and for conducting the anæsthesia, Prof M Naim for his encouragement and guidance, Mr S Mikhail for his valuable technical assistance, and Dr R C Mac Keith for correcting the draft of the paper and for his help in many other ways

In the first two weeks of life a raised serum-bilirubin level from any cause may lead to kernicterus In those who have died, necropsy has shown staining by bilirubin of certain cells in the central nervous system, principally in the basal ganglia The mechanism of this change is unknown, but there is evidence that it may be caused by an inhibitory action of excessive bilirubin on essential cellular respiratory activity

Day (1954) showed that oxygen uptake of rat brain is significantly reduced in the presence of bilirubin 20 mg per 100 ml, but that no such inhibition is found with biliverdin Zetterström and Ernster (1956), working with liver mitochondria, showed that bilirubin at a concentration of 20 mg or more per 100 ml exerts a powerful uncoupling effect on oxidative phosphorylation Lathe and Walker (1957) show that the livers of the newborn cannot conjugate bilirubin, which is unexcretable, to the glucuronides of bilirubin, which are excretable—the necessary enzymes being absent or deficient

---

* Present address Hillingdon Hospital, Middlesex

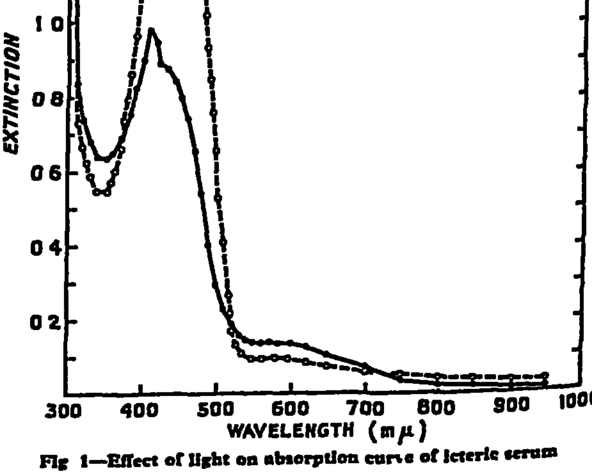

Fig 1—Effect of light on absorption curve of icteric serum

Mollison and Cutbush (1951) showed that the incidence of signs of kernicterus increases as the concentration of serum-bilirubin rises above 20 mg per 100 ml, and that below this figure ill effects are rare The prevention of a high level of serum-bilirubin, or the destruction of this substance, or its removal from the blood-stream, will prevent kernicterus This has hitherto been achieved by replacement transfusion Where experienced staff and good laboratory facilities exist, results are highly satisfactory (Norman 1957) However, such facilities are not universal, and an alternative approach seems desirable

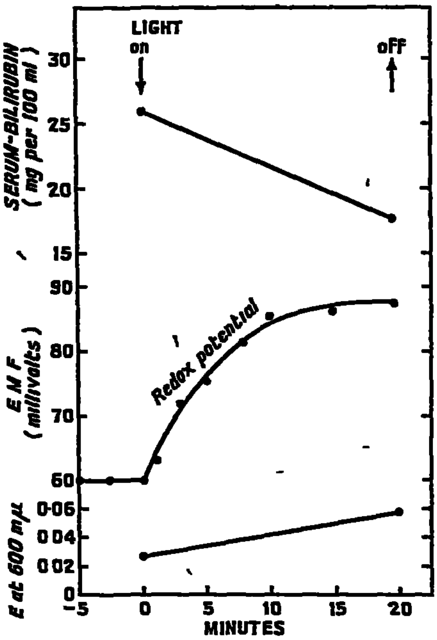

Fig 2—Effect of light on icteric serum.

Effect of Light on Serum-bilirubin

During serial estimations of the serum-bilirubin in jaundiced infants we noticed that their serum-bilirubin is highly photosensitive in vitro (Cremer, Perryman, Richards, and Holbrook 1957) We have studied this sensitivity and tried to apply it therapeutically

When icteric serum of infants is illuminated by white light, and the temperature is kept constant at 20°C, the characteristic 420 mμ absorption peak decreases and the absorption at the red end of the spectrum, around 550–650 mμ, increases a little (fig 1) At the same time the measured serum-bilirubin level is reduced and electromotive force (E M F) measurements show a positive increase in the oxidation/reduction (redox) potential of the system (fig 2) This indicates that, under the action of light bilirubin undergoes photo-oxidation or dehydrogenation to biliverdin or some intermediate products These substances are more polar, and therefore probably more easily excretable, than is bilirubin

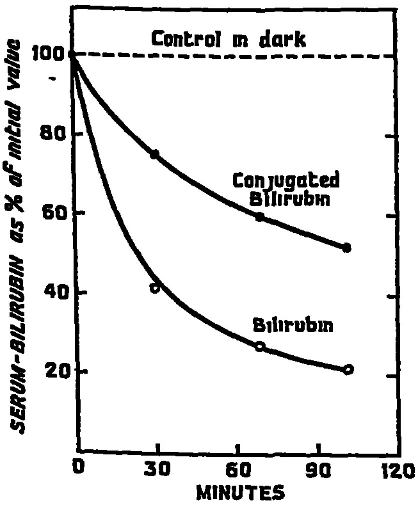

Fig 3—Effect of sunlight on serum-bilirubin.

Bilirubin (van den Bergh indirect pigment), the type of pigment greatly predominating in icteric infants, is some two or three times as photosensitive as is conjugated bilirubin (van den Bergh direct pigment) (fig 3)

These findings emphasise the need for special precaution in laboratories doing routine bilirubin estimations on jaundiced infants We now make a practice of enclosing all our blood-specimen tubes in light-tight containers if immediate analysis is not feasible We have found that specimens left in bright daylight may lose as much as 30% of their serum-bilirubin in an hour

Fig 4 shows the distribution of the photosensitivity effect over the visible spectrum

Clinical Applications

The subjects chosen for this study were all infants in the premature babies unit of the hospital The sister in charge of the unit had earlier reported the apparent fading away of the yellow pigmentation in the skin of jaundiced babies when they had been a short time in sunlight It was decided, therefore, to expose jaundiced infants to sunlight and assess the results quantitatively by serial determinations of serum-bilirubin

Before the exposure the general trend of the serum-bilirubin level was established by the micro-method devised for this purpose (Perryman, Richards, and Holbrook 1957) To avoid overheating or excessive ultraviolet radiation, the babies were placed naked in direct sunlight for fifteen to twenty minutes (according to the sun's intensity) and then withdrawn for similar periods before again being exposed to the sunlight. During the exposure the infants' eyes were protected by a simple plastic shield

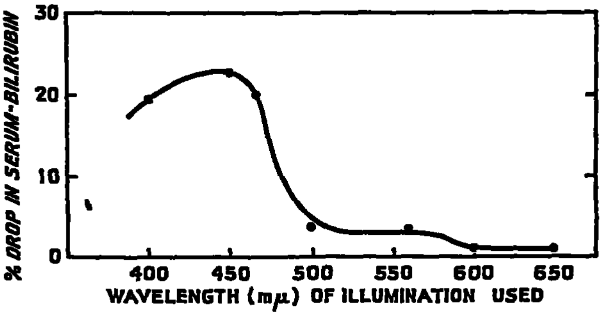

Fig 4—Spectral distribution of the photodestruction of serum-bilirubin

Jaundice quickly disappeared from the exposed areas of skin but persisted in areas which remained in the shade

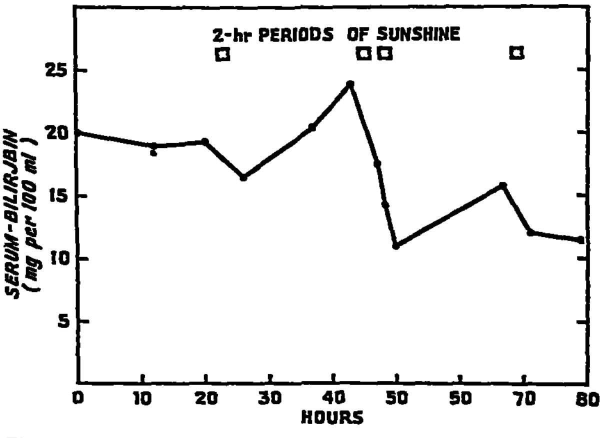

Fig 5—Sunshine treatment of an icteric infant with jaundice of prematurity (case 6)

TABLE I—EFFECT OF SUNLIGHT ON ICTERIC INFANTS

Case no	Birth weight (lb	oz)	Day of life	Serum-bilirubin before treatment (mg per 100 ml)	Duration of exposure (hours)	Resulting decrease in serum-bilirubin (mg per 100 ml)

10	5	3	5	19	3	4
			6	15	3	2
11	3	12	5	12	2	3
12	5	14	3	11	2	4
13	5	3	4	10	2	—2
			5	12	2	0

After this intermittent sunlight treatment, bilirubin levels were again measured

Fig 5 shows a typical result of this treatment Table I records the initial level and drop in serum-bilirubin in 13 premature infants with twenty test exposures These had the so-called "physiological jaundice" of prematurity, and in all (except case 13, where there was a rise) there was a definite drop in serum-bilirubin during the exposure In general, we found that the higher the initial serum-bilirubin level and the longer the exposure-time, the greater the fall in serum-bilirubin

In view of these results, we sought a source of artificial light instead of sunshine Guided by our work on the spectral distribution of the photosensitivity (fig 4), we examined various light sources Finally the apparatus illustrated in fig 6 was devised

This consists of a hemicylindrical stainless-steel reflector suspended on a movable gantry and adjustable for height Eight 24 in light blue fluorescent 40-watt discharge tubes (G E C), at 2 in separation, are arranged around the curve of the reflector The equipment is so made that a cot may be wheeled beneath the lights, and switch-gear provides that the illumination can be cut if less than the full power is desired This equipment gives light of very high intensity in the region of 420–480 mμ without any dangerous ultraviolet or X-ray components The height of the lamp from the infant is adjusted to make use of the small amount of radiant heat emitted for keeping the infant's body-temperature at 98–100°F

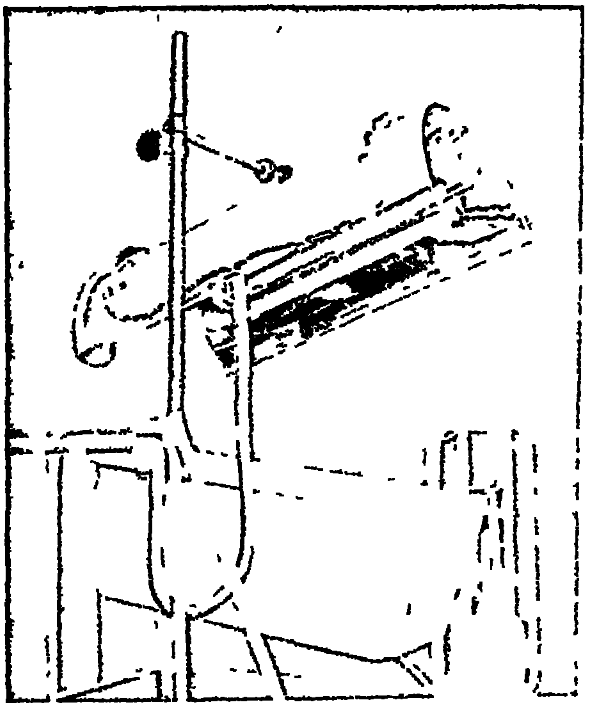

Fig 6—Artificial-light apparatus for cradle illumination of infants

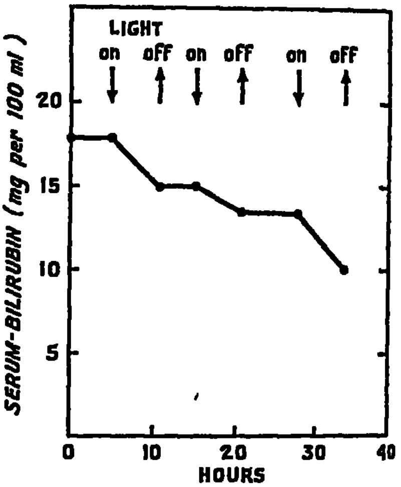

Fig 7—Effect of artificial-light treatment on a jaundiced premature infant (case 16)

Fig 7 shows the effect of this source of artificial light on an icteric premature infant, the coincidence of the drop in serum-bilirubin with the period of illumination is noteworthy

TABLE II summarises the results of twelve light-exposure tests in 9 jaundiced premature infants These all show small but significant drops in serum-bilirubin At first continuous illumination was used, but in the light of experience a routine of six hours in the lights followed by two hours out seems to give better results 2 infants with severe jaundice due to Rh incompatibility are not included in table II These failed to respond to the light treatment and exchange transfusion was necessary

TABLE II—EFFECT OF ARTIFICIAL LIGHT ON ICTERIC INFANTS

* Intermittent illumination 6 hours on, followed by 2 hours off

Discussion

Our results so far are insufficient for a complete statistical appraisal, but they encourage further work From our biochemical studies, it has become clear that a complex series of chemical changes is involved

Under the action of light, bilirubin seems to be dehydrogenated, and the role of hydrogen acceptors and photocatalysts is being investigated Several compounds accelerate the photodestruction of serum-bilirubin in vitro—e g, methylene-blue at a concentration of 10 μg per ml of serum, similarly toluidine-blue and cresyl-blue, though they are less effective, and riboflavine We suggest that the difference in degree of response to light treatment between one jaundiced infant and another and also the complete failure of some to respond may be related to lack of essential hydrogen acceptors or other factors in the circulating plasma We have found that in the first few days of life cœruloplasmin is absent from the blood-serum, which may have a bearing on this problem

No prospect can be entertained that this light treatment will prove a substitute for exchange transfusion in the erythroblastotic infant with active hæmolysis, but the method may be turned to clinical advantage in controlling the level of serum-bilirubin in cases of jaundice of prematurity

Summary

In some cases of neonatal jaundice the serum-bilirubin level is reduced by sunlight or by suitable artificial-light treatment

We should like to thank Dr R H Dobbs, consultant pædiatrician to this group, for his interest and encouragement, and Prof G H Lathe, of Leeds We are indebted to the group engineering department of the Southend Hospitals for the design and manufacture of the cradle illumination machine

THE effect of ketosis on the administration of Krebs-cycle metabolites has been extensively studied as a tentative approach to knowledge of this pathological condition It may be assumed, in fact, that ketosis develops whenever acetyl radicals are inadequately metabolised via the Krebs cycle, owing to a deficient availability of oxalacetate This pathogenic mechanism has also been postulated for diabetic ketosis (Thompson and King 1957), but Beatty and West (1955) did not detect any effect of the administration of succinic acid and malic acid on the ketonuria of alloxan-diabetic rats fed on Wesson oil, consequently they suggest that a deficiency of oxalacetic acid is not the cause of diabetic ketosis

To provide further evidence on this question the action of citrate and oxalacetate on experimental dietary and diabetic ketosis has been examined

Material

The rat and the dog were chosen for experimenting on because there is evidence that, in both species, the pathogenic mechanism of dietary ketosis (Crandall 1941, Deuel 1957) and alloxan-diabetic ketosis (Lukens 1948, Hoet and Young 1954) is essentially the same as in man However, because of the difficulty of obtaining stable ketosis of exclusively diabetic origin in the rat (Beatty and West 1955) and dietary ketosis in the dog (Crandall 1941) each type of ketosis was investigated in only one of these animal species Nevertheless a comparison between the results seems legitimate because, as mentioned above, the pathogenic mechanisms are essentially the same in the two species

TABLE I—EFFECT OF CITRIC ACID AND OXALACETIC ACID ON DIETARY KETOSIS

Treatment	No of experiments	Ketone bodies (mg per 100 g of body-weight in 24 hr)
Fasted 24 hr	8	1 0±0 5
Butyric acid	5	6 9±2 6
Butyric acid + 4 5 mM of oxalacetate	4	2 3±0 7
Butyric acid + 4 5 mM of citrate	4	1 6±0 7
Butyric acid + 6 0 mM of oxalacetate	4	0 6±0 3
Butyric acid + 6 0 mM of citrate	4	0 7±0 4

TABLE II—TYPICAL EXAMPLE OF EFFECT OF CITRATE AND OXALACETATE ON BLOOD-SUGAR AND KETONE-BODY LEVELS OF ALLOXAN-DIABETIC DOG FASTED FOR 6 HR

Administration of	Substance	Blood-level (mg per 100 ml)		
		Before administration	90 min after administration	180 min after administration
Citrate Na salt	Sugar	380 0	470 0	380 0
	Ketone bodies	16 7	16 5	15 0
Oxalacetate Na salt	Sugar	310	380 0	330 0
	Ketone bodies	25 3	23 3	22 3

Dietary ketosis was induced by feeding butyrate to female albino rats, the 24-hr urinary excretion of ketone bodies was determined by the method described by Greenberg and Lester (1944) with and without administration of citrate and oxalacetate (table I) A 10% solution of butyric acid adjusted to pH 6 0 was administered in the dose of 2 ml per 100 g of body-weight by stomach-tube to rats fasted 15 hr The millimols of the test substances injected intraperitoneously denote the dosage per kg of body-weight for 24 hr Oxalacetate was prepared according to the method described by Heidelberger (1953)

Experimental details and results are reported in table I

Diabetic ketosis was studied in alloxan-diabetic dogs, blood-sugar and ketone-bodies levels were determined before and after intravenous injection of citrate and oxalacetate (table II) Blood-sugar levels were determined by the method described by Somogyi (1945), and ketone bodies, expressed as acetone by that of Greenberg and Lester (1944) Citrate and oxalacetate were administered intravenously in a single dose of 3 mM per kg of body-weight The time intervals between the administration and the determinations were chosen on the basis of Crandall's (1941) results and are reported with other experimental details and data in table II

Results

The results show that dietary ketonuria is practically abolished by intraperitoneal injection of either citrate or oxalacetate

Diabetic ketosis, on the other hand, is not significantly influenced either by citrate or by oxalacetate injected intravenously

The discrepancy between the results obtained in diabetic and in dietary ketosis suggests that the pathogenic mechanisms responsible for these two conditions are fundamentally different

Diabetic ketosis may not be attributable, as dietary ketosis is, to a deficiency of oxalacetate or of citrate but rather, according to Beatty and West (1955), to a disturbance in the Krebs cycle

This work was aided by a grant from the Rockefeller Foundation

REVERSAL OF URINARY DIURNAL RHYTHM FOLLOWING HEAD INJURY

R W Payne
M A, M B Cantab
DEMONSTRATOR IN CHEMICAL PATHOLOGY

H E de Wardener
M B E, M D Lond, M R C P
SENIOR LECTURER IN MEDICINE

ST THOMAS'S HOSPITAL MEDICAL SCHOOL, LONDON, S E 1

The presence of a diurnal rhythm of urinary excretion is well established (Vogel 1854, Quincke 1877, Simpson 1924, Norn 1929, Manchester 1933, Gerritzen 1940, Borst and de Vries 1950, Stanbury and Thomson 1950) Reversal of this rhythm has been reported in various conditions in which generalised œdema occurs—e g, congestive cardiac failure, malnutrition, cirrhosis of the liver, and the nephrotic syndrome (Quincke 1893, Sinclair 1949, Borst and de Vries 1950, Stanbury and Thomson 1951, Goldman 1951) The normal rhythm is also reversed in habitual night-workers (Norn 1929) and in some cases of Addison's disease (Levy et al 1946)

This paper describes a case in which reversal of the urinary diurnal rhythm followed a head injury The normal pattern of diurnal rhythm was also studied in five normal subjects under identical conditions

Material

Patient

A man, aged 40, was admitted to hospital under the care of Prof F T G Prunty in November, 1956, for investigation of progressive obesity accompanied by nocturia Apart from malaria and bacillary dysentery in 1936, he had been fit until July, 1945, when he was involved in a motor-cycle accident and was unconscious for several hours He had retrograde amnesia covering three days and post-traumatic amnesia covering seven days There was no external wound, but radiography revealed a fracture of the left parietal bone The patient was in hospital four months Electroencephalography before his discharge showed nothing abnormal In January, 1946, he began to have attacks of jacksonian epilepsy involving the left angle of his mouth, and in spite of phenobarbitone therapy he continued to have three or four mild attacks a year

* Values are percentages of mean total daily output except osmolality, which is mean of each period for three days

He denied any symptoms resembling narcolepsy and stated that his sleep pattern was normal Until 1945 his weight remained steady at about 64 kg, he then progressively gained weight, and on admission he weighed 118 kg He had not noticed any great increase in appetite, nor did he complain of excessive thirst. In 1952 he started to pass urine once or twice during the night and had done so ever since. He had no other urinary symptoms, and he stated that he did not drink large amounts of fluid in the evening or during the night.

On physical examination, apart from generalised obesity, nothing abnormal was found.

Investigation of renal function revealed no abnormality the specific gravity of the urine after deprivation of fluids was 1 028 and after the subcutaneous injection of vasopressin tannate 5 units it was 1·031. A twenty-four-hour creatinine clearance was 119 ml. per minute A glucose-tolerance test was normal The total daily urinary excretion of 17-ketosteroids and 17-ketogenic steroids and the response to corticotrophin were normal. A radiograph of the skull, a right carotid angiogram, and an electroencephalogram were within normal limits

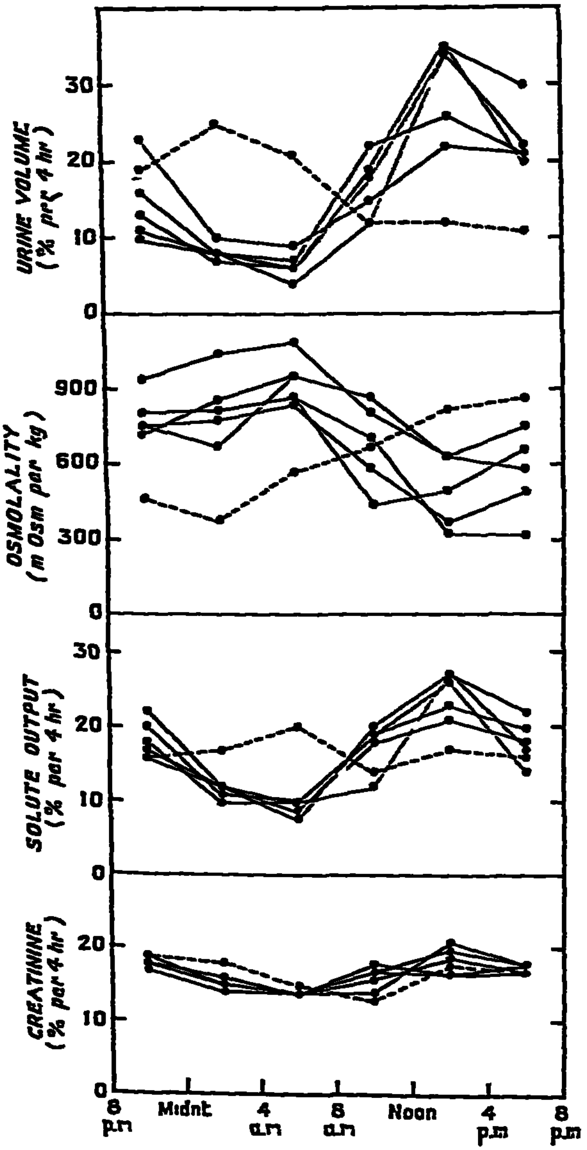

FIG 1—Diurnal changes in the flow and osmolality of the urine, and in total solute and creatinine excretion in normal subjects (continuous lines), and in the patient (interrupted lines). Values are percentages of mean total daily output except for the osmolality which is the mean for each period for three days.

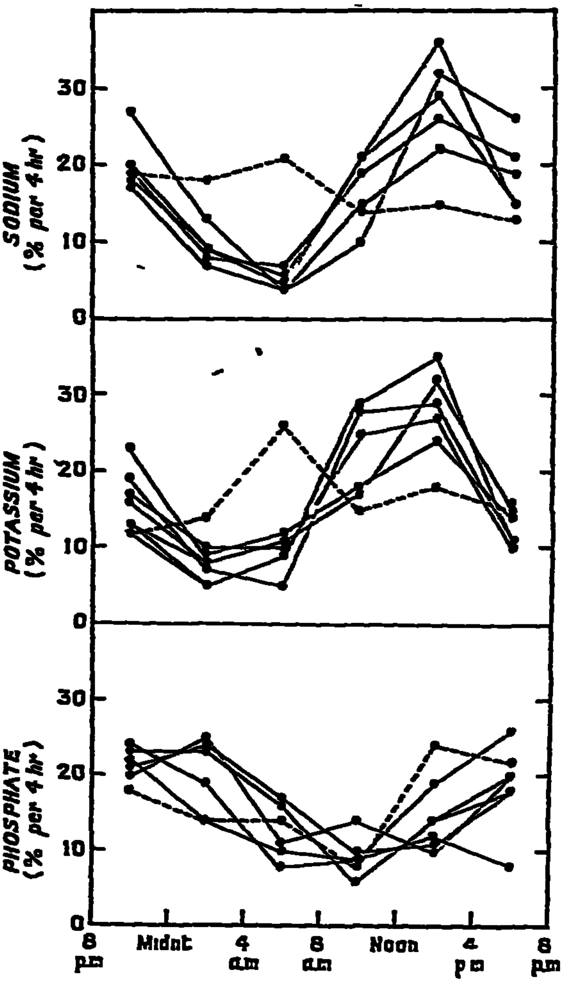

FIG 2—Diurnal changes in urinary excretion of sodium, potassium and phosphate in normal subjects (continuous lines) and patient (interrupted line).

Healthy Volunteers

Five healthy male volunteers were admitted to the metabolic ward for investigation.

Methods

During the three-day period of study both the patient and the normal subjects were ambulant by day but remained in the ward They were allowed to take as much food and fluids as they liked by day but nothing between 8 P.M and 6 A.M Urine was collected four-hourly from 8 P.M for seventy-two hours, eighteen specimens being obtained from each person. To distract attention from the volume of urine, and to reduce emotional influences on the flow of urine, the controls were told that the investigation concerned the pattern of urinary excretion of 17-ketosteroids and that this necessitated four-hourly collections of urine.

The volume of each specimen of urine was measured The osmolality of the urine was determined by measuring the depression of its freezing-point with a thermistor (de Wardener and del Greco 1955), the concentration of sodium and of potassium in the urine with a Barclay flame-photometer using an internal standard, creatinine by the method of Peters (1942), chloride by the method of van Slyke and Hiller (1947), and phosphate by Briggs' (1922) method. The 17-ketosteroids and 17-ketogenic steroids were determined by Dr R. V Brooks using the method of Norymberski (Gibson and Norymberski 1954)

The constituents of each of the eighteen specimens of urine from each person were determined by the above methods The mean outputs of the six corresponding four-

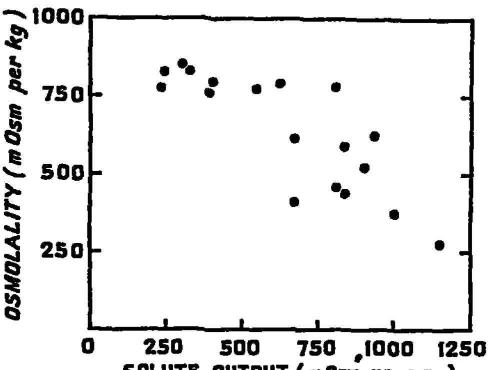

Fig. 3—Osmolality and excretion of solutes in all four-hour specimens of urine obtained from normal subject no. 5.

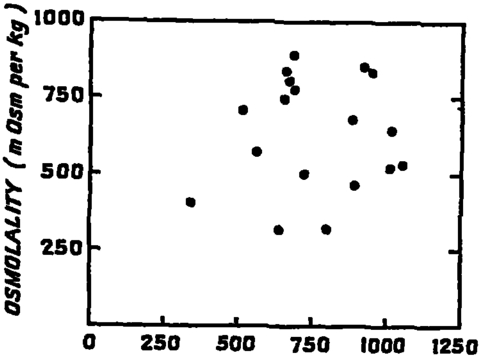

Fig. 4—Osmolality and excretion of solutes in all four-hour specimens of urine obtained from the patient.

hour periods each day were calculated, and from this the mean total daily output was determined. The mean output of each four-hourly period has been expressed as a percentage of the mean total daily output.

Results

The results are given in the accompanying table.

Normal Subjects

The normal subjects showed little day-to-day change in their pattern of urinary excretion, and the patterns were similar in all of them. The highest and lowest rates of excretion mentioned below represent the mean of all five subjects during any one four-hour period.

The output of water, total solutes, sodium, potassium, chloride, and creatinine increased during the day being greatest from noon to 4 P.M., and at this time the urine was most dilute. Conversely, the excretion of these same substances decreased during the night, being least from 4 A.M. to 8 A.M., except for potassium which was usually lowest in the previous period—i.e., from midnight to 4 A.M. The urine was most concentrated from 4 A.M. to 8 A.M. (figs 1 and 2).

The excretion of water, sodium, potassium, and chloride showed the greatest diurnal changes, their highest excretion-rate was usually at least four times their lowest. Changes in the output of total solutes were less marked, the highest excretion-rate being less than three times the lowest. The excretion of creatinine fluctuated even less, the highest excretion-rate being 1.4 times the lowest. There was an inverse relationship between the total output of solutes and the osmolality of the urine (fig 3).

The rhythm of the urinary excretion of phosphate was the reverse of the other substances studied and was more variable both from one person to another and from day to day. The highest excretion-rate was from 8 P.M. to midnight and the lowest from 8 A.M. to noon (fig 2).

Four-hour excretion-rates of 17-ketosteroids and 17-ketogenic steroids were variable but were lowest by night and highest in the forenoon; in some subjects they rose again in the evening. Changes in the excretion-rates of these steroids seemed to be unrelated to changes in the excretion-rates of the other constituents of the urine.

Patient

In the patient the diurnal rhythms of urinary excretion of all the substances studied differed from those found in the normal subjects, but were consistent from day to day.

The output of water, total solutes, sodium, potassium, and creatinine increased during the night. The highest excretion-rate of water was from midnight to 4 A.M. and preceded the highest excretion-rate of total solutes, sodium, and potassium by four hours. The urine was most dilute during the period of highest water excretion.

Throughout the day the output of water, total solutes, sodium, and potassium was less than during the night, and there was little difference between the three periods. The concentration increased during the day and was greatest from 4 P.M. to 8 P.M. The pattern of excretion of creatinine was similar to that in the normal subjects, but the lowest excretion-rate was four hours later, from 8 A.M. to noon; it was unrelated to changes in the output of total solutes (fig 1).

As in the normal subjects, the excretion of water, sodium, and potassium showed the greatest diurnal changes, but they were less pronounced. The highest excretion-rates of water and potassium were about twice, and those of sodium and total solutes only 1.5 times the lowest. There was no relationship between the output of total solutes and the osmolality of the urine (fig 4).

The pattern of urinary excretion of phosphate resembled that in the normal subjects, but both the lowest (8 A.M.–noon) and the highest (noon–4 P.M.) rates occurred by day and in consecutive periods (fig 2).

The urinary excretion of 17-ketosteroids and 17-ketogenic steroids was variable, as in the normal subjects, but appeared to show a normal diurnal rhythm.

Discussion

In the normal subjects, the diurnal patterns of urinary excretion of water, sodium, potassium, chloride, and creatinine were similar to those observed by other workers (Simpson 1924, 1926, Norn 1929, Manchester 1933, Gerritzen 1940, Smits 1947, Borst and de Vries 1950, Stanbury and Thomson 1950, Goldman 1951). It was also confirmed that the urinary excretion of phosphate varies considerably more than that of water and strong electrolytes. The excretion of water and total solutes decreased during the night, whereas the osmolality of the urine increased. In contrast, during the day the excretion of water and total solutes increased, and the osmolality of the urine decreased. There was an inverse relationship between the output of solutes and the osmolality of the urine, and the rhythms of excretion of water and osmolality total solutes were synchronous.

In the patient the most striking feature was a reversal of the normal pattern of excretion of water, more water being excreted by night than by day. There was also a reversal of the diurnal rhythm of urinary excretion of total solutes, sodium, and potassium, and some change in the excretion of phosphate and creatinine. There was no relationship between the output of solutes and the osmolality of the urine, and the rhythms of excretion of water and total solutes were not synchronous.

The rate of flow of the urine is determined by (1) the concentration of antidiuretic hormone (A.D.H.) in the plasma (Verney 1946), (2) the tubules' capacity to respond to A.D.H. (Epstein et al. 1957, de Wardener and

Herxheimer 1957), and (3) the rate of solute output (McCance 1945, de Wardener and del Greco 1955) The nocturia in this patient appears to have been induced by a change in at least two of these mechanisms Unless large amounts of vasopressin are administered, it is impossible to differentiate between (1) and (2), but one of these two mechanisms must have been responsible for the evening rise in urine flow and fall in urine concentration (from 830 to 470 m Osm kg of the urine in the periods 4 P M - 8 P M. and 8 P M -midnight, because the output of solutes in these two periods was identical Nevertheless in the following period (from midnight to 4 A M) the high rate of urine flow was maintained, at least in part, by an increased output of total solutes This occurred at a time when the initial cause of the nocturnal diuresis was waning, for as the solute output rose the urine became more concentrated It is therefore concluded that the increased excretion of water at night in the patient was due to a nocturnal increase in the output of solutes, and in addition to at least one of the two mechanisms which are independent of the output of solutes

It is probable that in normal subjects the diurnal variation in water excretion is also controlled by factors other than the solute output, though this is not apparent under normal conditions Lewis and Lobban (1956), for instance, have shown that the diurnal rhythm of urinary excretion of water and that of electrolytes can become dissociated in certain circumstances In addition, Lewis and Lobban (1956) and Mills and Thomas (1957) have shown that the diurnal excretion of individual electrolytes may vary independently These findings suggest that the mechanisms responsible for the diurnal rhythms of the urinary excretion of water and of individual electrolytes are independent

In the present patient a reversal and dissociation of the normal urinary diurnal rhythms of water and electrolyte secretion followed a head injury, and was associated with the onset of epilepsy and obesity This suggests that the site of the control of the various mechanisms responsible for the diurnal rhythms of urinary excretion is in the brain, possibly in the hypothalamus—a suggestion previously advanced by Mills (1951) and by Lewis et al (1956) from their experiments on normal subjects

Summary and Conclusions

A case is reported in which reversal of the urinary diurnal rhythm, epilepsy, and obesity followed a head injury

The daily patterns of urinary excretion of water, total solutes, sodium, potassium, chloride, phosphate, and creatinine and of urine osmolality were studied in five normal subjects and compared with those in the patient

The high rate of excretion of water at night in the patient appears to have been due to an increase in solute output, and to a mechanism independent of the solute output

It is suggested that the mechanisms responsible for the diurnal rhythms of urinary excretion of water and electrolytes are independent.

It is further suggested that the site of control of these mechanisms is in the brain, possibly in the hypothalamus

We wish to thank Prof F T G Prunty for encouragement and permission to publish, Dr R R McSwiney for helpful criticism, Dr R V Brooks for estimating the urinary steroids, the volunteers, the sisters and nurses for their helpful cooperation, the staff of the William Dunn Laboratory (especially Mr R Hurst, Mr R Smith, Mr R Hale, and Miss S Jones), and Miss J Bethell for technical assistance

EXTENT OF THE INFARCT IN THE ANTERIOR LOBE OF THE HUMAN PITUITARY GLAND AFTER STALK SECTION

P M DANIEL *

A QUESTION of considerable importance, both to neurosurgeons and to those interested in the treatment of cancer, is the efficiency, or otherwise, of section of the pituitary stalk as a means of producing necrosis of the anterior lobe of the gland Although stalk section is simpler than total hypophysectomy, its efficacy is not yet proved

The following case shows the extent of the lesion produced

Case-report

A woman, aged 39, had had a left radical mastectomy performed by Mr J Heriot of King's College Hospital in July, 1956 She remained well till March, 1957, when she was found to have a left pleural effusion. She was given methyl testosterone and in July was admitted to the Guy's-Maudsley neurosurgical unit (no 1767) She now had metastases on the left lower chest wall, the left pleural cavity was virtually obliterated by growth, and there were metastases in bones

At the urgent request of the patient and her relatives, an operation was performed on Aug 9 (P H S) A frontal osteoplastic flap was turned and the right frontal lobe was raised to expose the pituitary stalk. This was cut and a plate of cold-curing resin,† shaped to fit beneath the optic chiasma and over the diaphragma sellæ, was inserted to separate the cut ends of the stalk and thus prevent any possible regrowth of vascular connections (fig 1) (Harris 1950, Harris and Jacobsohn 1952, Jacobsohn 1954)

---

* Assisted by a grant from the Bethlem Royal and Maudsley Hospital Research Fund

† Simplex pentacryl', Dental Fillings, Ltd , 49, Grayling Road, London, N 16

Eight days later the patient developed congestive cardiac failure and pericarditis She died on Aug 28

Necropsy (P M D)

There were multiple secondary deposits of carcinoma, and severe bronchopneumonia The brain showed minimal operative trauma and contained no secondary deposits The plastic plate (fig 1) lay in excellent position over the diaphragma sellæ. At the proximal cut end of the pituitary stalk was a little rounded knob resembling a tiny neuroma on a peripheral nerve—an appearance which we have commonly seen after hypophysectomy

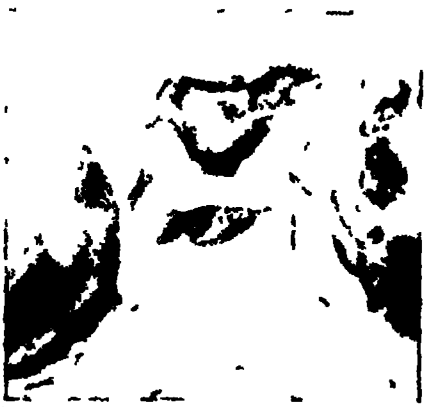

Fig 1—Photograph, taken at necropsy, after removal of the brain, showing the plastic plate in situ, lying beneath the optic chiasma

Findings in the Pituitary Gland

The gland was fixed in formol-saline and cut sagittally into five blocks and embedded in paraffin wax Sections were taken from one surface of each block and stained with hæmatoxylin and eosin, iron hæmatoxylin and van Gieson's mixture, Mallory's trichrome method, Heidenhain's azan method, Mann's method, and the periodic-acid Schiff method

The sections showed extensive infarction of the anterior lobe There was a narrow rim of living cells all round the periphery, but deep to this, in the lateral portions, the epithelial tissue was wholly necrotic (fig 2) In the median part of the gland the infarct was confined to the anterior (ventral) half of the anterior lobe, and the cells in the posterior (dorsal) half were alive (fig 3) The situation and the extent of the living and necrotic tissue is shown in fig 4, which is a reconstruction based on sections taken from the five blocks

Fig 2—Sagittal section through the lateral part of the pituitary Only anterior-lobe tissue is present Note the massive infarct (pale) and the narrow peripheral rim of surviving anterior-lobe cells (dark) (hæmatoxylin and eosin ×9)

From the infarct the epithelial cells had completely disappeared the whole of its central area was occupied by structureless debris with no nuclear remains Round the periphery of this structureless mass there was a layer of young granulation tissue The boundary between the granulation tissue and the living cells was sharply defined No inflammatory cells were present around the infarct In the living anterior-lobe tissue, the sinusoids were dilated and filled with red cells, and the tissue in general appeared œdematous, the epithelial cells, though alive, appeared distinctly abnormal They were, on the whole, unusually small, had lost their regular arrangement, and tended to be heaped together in irregular, closely packed groups Many cells had a glassy acidophilic cytoplasm, and few showed any distinct intracytoplasmic granules

The posterior (neural) lobe was invaded by carcinoma cells, which is not unusual in mammary carcinoma In this case the lobe was probably invaded before the stalk was cut The neural tissue itself was shrunken and fibrotic, there was also an apparent increase in the cellularity of this tissue and in the number of blood-vessels These latter appearances were similar to those seen in the posterior lobe of goats 3–4 weeks after pituitary-stalk section (Daniel and Prichard 1958)

Comment

The large extent of the infarct in the anterior lobe in this case is evidence that most of the anterior lobe derives its blood-supply from the long hypophysial portal vessels of the pituitary stalk, which were severed at operation The posteromedian area of the anterior lobe survived because this area is supplied by the short hypophysial portal vessels, which have their origin in the lower infundibular stem (fig 5), and thus is supplied by the intact inferior hypophysial arteries

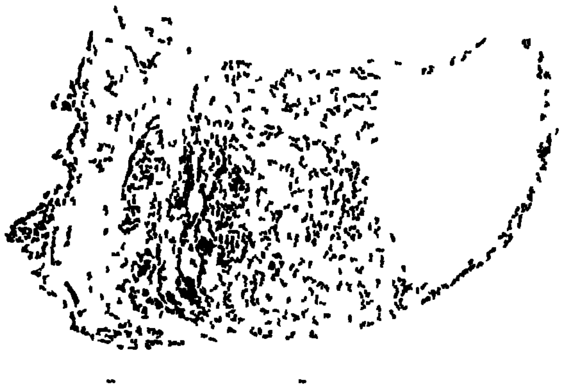

Fig 3—Approximately mid-sagittal section through the pituitary Posterior lobe (somewhat fragmented and with carcinoma tissue in it) seen on the left In this plane there is an area of surviving anterior-lobe tissue (dark) occupying the posterior half of the anterior lobe, but this area was confined to a median zone (see fig 4) On the right the anterior lobe is infarcted (pale area) (hæmatoxylin and eosin ×7½)

The anterior lobe of the human pituitary has no direct arterial blood-supply (Xuereb, Prichard and Daniel 1954a) This is also the case in some animals (but *not* the rabbit), and a comparable picture of massive infarction of the anterior lobe is regularly seen in sheep, goats, and rats after pituitary-stalk section or cauterisation of the hypophysial portal vessels in the pituitary stalk (Daniel and Prichard 1956, 1957a, 1957b, 1957c, 1958) These animals, like our patient, have a small area of surviving anterior-lobe tissue, which does not derive its blood-supply from the stalk and also a narrow peripheral rim of surviving anterior-lobe cells, whose survival we attribute to the diffusion of oxygen and metabolites from the adjacent, highly vascular, dura mater

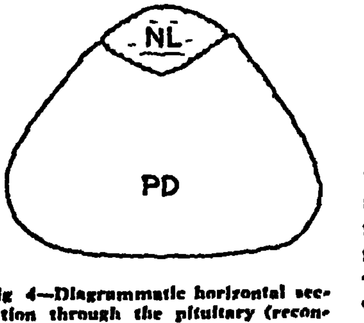

Fig 4—Diagrammatic horizontal section through the pituitary (reconstructed from sections) showing extent of the infarct (pale) and the surviving tissue (dark) in the anterior lobe (P D) N L, neural (posterior) lobe

Fig 3 alone is misleading as to the extent of the *infarct* The

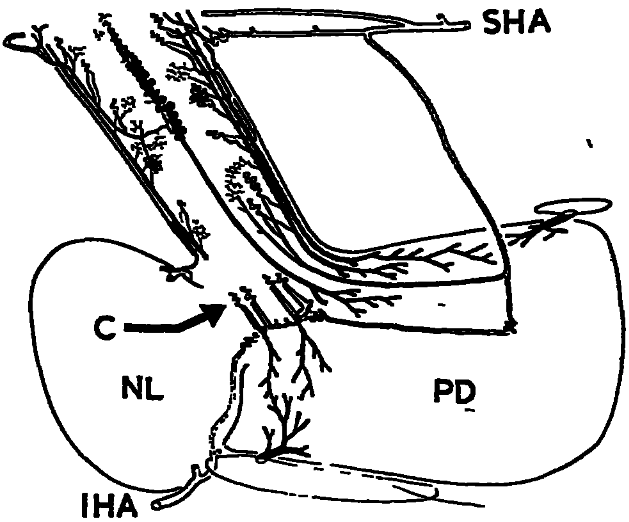

Fig 5—Diagram showing the blood-supply of the anterior lobe (P D) of the human pituitary, in sagittal section

Section through the pituitary stalk does not interfere with the blood-supply to the capillary loops (C) in the lower infundibular stem It is the blood-flow through the short portal vessels draining these capillary loops which has kept alive the posteromedian area shown in figs 3 and 4

N L, neural (posterior) lobe, S H A, superior hypophysial artery, I H A, inferior hypophysial artery (This diagram is modified from fig 16, Xuereb et al 1954b, and further explanations will be found in that paper)

large mass of living epithelial cells seen here is, in fact, confined to a narrow median strip, and sections from the more lateral blocks (fig 2) show that much the greater part of the lobe is necrotic (fig 4) To see the extent of the necrosis at a glance it would be wise to cut the pituitary horizontally, as was done by Russell (1956), who demonstrated very similar appearances

Our patient survived for 3 weeks after operation In goats (Daniel and Prichard 1958), results were very similar to those reported here, and there was a suggestion of some regeneration of anterior lobe cells after a few days

In the goats, as in our patient, the abnormal appearance of the epithelial cells surviving in the anterior lobe was very striking This appearance, we believe, indicates that the living cells had lost much of their functional activity as a result of the stalk section, because the remaining part of the primary capillary bed (in the lower infundibular stem) had been "denervated" by section of the pituitary stalk The neural component of the neurovascular link between the hypothalamus and the anterior lobe, which Green and Harris (1947) and Harris (1955a, 1955b) consider essential for the proper maintenance of anterior-lobe function, was now missing

The degeneration of the neural tissue in the posterior lobe was not, we think, primarily due to carcinomatous infiltration, since the same picture was seen in the posterior lobes of the goats 3–4 weeks after stalk section, and is only to be expected after section of the nerve tracts

Summary and Conclusions

In a woman with carcinomatosis, section of the pituitary stalk led to infarction of the anterior lobe except for the posterior half of the median part and a few cells round the periphery (The full extent of the necrosis in the anterior lobe after section of the pituitary stalk is not revealed by median sagittal sections)

Section of the pituitary stalk in man will not cause necrosis of the entire anterior lobe of the pituitary gland But even in "total" hypophysectomy fragments of this lobe are almost always left behind in the sella turcica, and this residual tissue may be found in patients with a successful remission of the malignant growth Moreover, all reports of extensive infarction of the anterior lobe in man mention a narrow peripheral layer of surviving anterior-lobe cells However, from experimental work on animals, it seems probable that any surviving cells, when isolated from the hypothalamus either by pituitary stalk section or by subtotal hypophysectomy, have their secretory activity so much reduced that they are no longer endocrinologically important Histologically they are abnormal in appearance

GANGRENE OF THE EXTREMITIES FOLLOWING CARDIAC INFARCTION AND NORADRENALINE THERAPY

D Greenbaum
M B Lond , M.R C.P
MEDICAL REGISTRAR, LONDON HOSPITAL, E 1

Symmetrical peripheral gangrene is a rare complication of heart-disease with circulatory failure The following case is of interest in that the gangrene was of unusual extent and the patient had been treated with noradrenaline

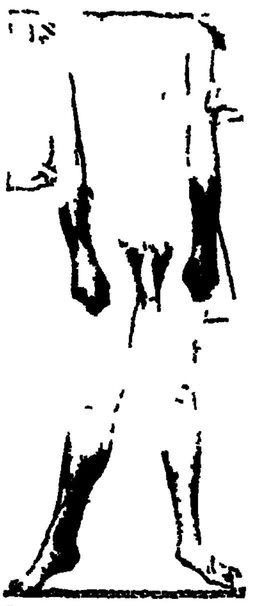
Case-report

A man, aged 56, was admitted to the London Hospital on Aug 18, 1957, having collapsed three hours before with severe lower substernal pain There was no previous history of significant ill health

On examination his extremities were cold and blue, his skin was pale and clammy, and his temperature was 95 5°F His pulse was feeble, rhythm regular, rate 40, and apex-beat impalpable, and the heart sounds were distant, with gallop rhythm There was no jugular venous distension, and no crepitations were heard at the lung bases The blood-pressure was 80/50 mm Hg Electrocardiography showed gross ST and T changes in all leads and complete heart-block

Treatment and course —Morphine and anticoagulants were given, the latter being discontinued after a vomit of about a pint of blood twelve hours later Four hours after admission there was no change in the patient's general condition and blood-pressure and an intravenous infusion of noradrenaline 1 200,000 in 5% glucose was begun The concentration was increased to 1 100,000 after about an hour to reduce the amount of intravenous fluid given The blood-pressure rose almost immediately and was maintained at about 110 mm Hg systolic and 70 mm Hg diastolic The pulse-rate rose to 80, and electrocardiography showed that sinus rhythm had returned There was also concurrent improvement in the patient's general condition The infusion was maintained for sixty-eight hours, after which the blood-pressure spontaneously remained normal 20 mg of noradrenaline was given on the first day, 16 mg on the second day, and 8 mg on the third, the rate of infusion being adjusted according to the blood-pressure.

Ordinary transfusion needles were used and the site of infusion was changed twice—at points just above the wrist in both arms, and above the internal malleolus in the right leg Towards the end of the third day the peripheral pulses became difficult to feel On the fourth day the patient complained of stiffness of the fingers of his left hand, and during the next two days patches of gangrene appeared on his hands and feet Thereafter gangrene spread gradually up all four limbs to the extent shown in the accompanying figure No urine was passed during the first thirty-six hours Measurements were not made after that, because of incontinence, but the flow appeared to be adequate, and a catheter specimen had a specific gravity of 1 025 The patient became delirious and progressively weaker and developed moderate engorgement of his jugular veins and a few crepitations at his lung bases He died fourteen days after admission The hæmoglobin on the fifth day was 70%, and the blood-urea on the day of death 212 mg per 100 ml



Gangrene of all four limbs

Necropsy revealed extensive cardiac infarction The whole of the posterior wall of the right ventricle, the posterior two-thirds of the interventricular septum, and the whole of the posterior wall of the left ventricle were necrotic The left coronary artery, which rose from the right aortic sinus and wound round the aorta, was much smaller than usual, most of the blood-supply to the heart coming from the right coronary artery, which was occluded 2 cm from its origin by a thrombus 4 5 cm long surrounded by a crescent of atheroma There was moderate atheroma throughout the aorta, and there were a few streaks in the carotid and femoral arteries The limb arteries were shown either by dissection or injection radiography to be patent and apparently free from thrombus as far as the line of demarcation of the gangrene There were a few petechial hæmorrhages in the stomach, the liver and the spleen were congested, and the kidneys appeared normal both to the naked eye and on microscope There was moderate pulmonary œdema, and a few ante-mortem thrombi were found in some of the smaller pulmonary arteries Apart from the limbs, the testes were the only organs to show ischæmic necrosis

Discussion

Fishberg (1938) observed that, in heart-failure, the antecubital veins might be collapsed when the jugular veins were distended, and he postulated selective vasoconstriction conserving the circulation for vital organs Freis et al (1952) considered that peripheral vasoconstriction in cardiac infarction was a reflex mechanism produced by a reduction in the stroke-volume of the heart Gangrene of the extremities may be considered to be an unfortunate effect of this compensatory mechanism

During the past twenty years several reports of this complication have appeared Perry and Davie (1939) observed it in hypertensive heart-failure, Abrahams (1948), reported incipient gangrene in paroxysmal tachycardia, and Swan and Henderson (1951), Schulz and Knobloch (1953), Bird et al (1954), and Caserta et al (1956) describe it in cardiac infarction

In the present case the use of noradrenaline must have made an important contribution to the vasoconstriction that led to gangrene The spread of the gangrene for eleven days after the infusion had been stopped indicates the equal or greater importance of the low cardiac output These two factors may explain the remarkable extent of the gangrene In the other published cases it usually involved little more than the tip of the nose and the digits

Although local necrosis at or near the site of infusion is not uncommon, I have not been able to find a published report of symmetrical peripheral gangrene after the use of noradrenaline The doses of noradrenaline given in the present case were fairly large, but larger doses have been given in similar circumstances by various workers—e g, Smith and Guz (1953)—without ill effect Caserta et al (1956) used mephentermine sulphate, another powerful peripheral vasoconstrictor, but there was a clear interval between stopping the drug and the development of gangrene Humphreys et al (1955) described several cases of skin gangrene following noradrenaline therapy, but these all appeared to be due to local leakage of the drug into the tissues This mechanism was not important in the present case, because the left leg, which received no infusion, became gangrenous like the other limbs

I must thank Dr R R Bomford and Prof D S Russell for permission to publish

INSTRUMENT TO AID VOICE-TRAINING OF PROFOUNDLY DEAF CHILDREN

G R G PLANT
M C, M A Cantab

THE wearing of hearing-aids is of great help to partially deaf children, and the introduction of auditory training with powerful group hearing-aids in the children's classrooms has proved to be of benefit to children with very limited hearing, but the deafness of many grade-III pupils at schools for the deaf is so profound that they can derive little benefit from auditory equipment, even of the most powerful kind, and for these children reliance continues to be placed on speech-training methods which accept the fact that they are unable to hear either their own voices or those of their teachers

In such training a profoundly deaf child can be taught how to coordinate the various parts of his mouth and throat so as to produce the different types of vowel and consonant sounds which make up speech, and in time he will learn how to put the sounds into order to form words and sentences However, an aspect of speech which he cannot understand is the variation in frequency, or "pitch", that people with normal hearing impart to their voices during conversation This upward and downward variation in the fundamental frequency of the vocal cords, known as "voice inflexion", is used extensively in ordinary speech to convey intelligibility and meaning, and experiments show that a frequency variation of almost an octave is often used Because there is no satisfactory way of teaching a profoundly deaf child how to vary the pitch of his voice, everything that he says tends to be delivered on one constant monotone or with faulty voice inflexions Thus, however clearly he may have learnt to enunciate his words, ordinary people find his speech peculiar and difficult to understand

Previous Apparatus

In an endeavour to meet this situation various forms of visual pitch-indicating apparatus have been devised during the past quarter of a century, but, so far as is known, none of the apparatus has yet been considered to be sufficiently simple or robust for it to be manufactured and brought into general use for children at schools for the deaf

Frahm (1901) described an electromagnetically operated bank of spring reeds for indicating varying frequency

Hunt (1935) described a direct-reading frequency meter using two thyratrons, and suggested that it would help the deaf

Walton (1936) described an optical recording and frequency-indicating apparatus for analysing sound-waves magnetic circuits being used in parallel

Obata and Kobayashi (1937) described a direct-reading pitch recorder for indicating the fundamental pitch level in music and speech

Coyne (1938) described a voice-pitch indicator having a series of tuning forks, each operating a lamp

Sterne and Zimmermann (1939) described a voice-inflexion indicator in which seven lamps were arranged to be lit by thyratrons the number of lamps alight at any time varying in accordance with the fundamental frequency of the applied wave.

Horwitch (1948) described inflexion apparatus for the speech training of deaf persons, using eight reed filter circuits

Jones (1956) described a tonometer for linguists and deaf persons, using a bank of electromagnetically operated spring reeds

Present Apparatus

Some experiments which I started a few years ago have now led to the development of a new voice-training instrument, whose principal purpose is to demonstrate to a deaf child the pitch of his voice while he is speaking

The overall size of the first prototype instrument is 9 inches×9 inches×14 inches, and it is believed that there will not be any difficulty in manufacturing it. Much assistance has been afforded to me in the final stages of development of the prototype by Miss E M Johnson, headmistress of the Old Kent Road School for the Deaf, London, and preliminary trials being conducted at the school with profoundly deaf children are showing considerable promise

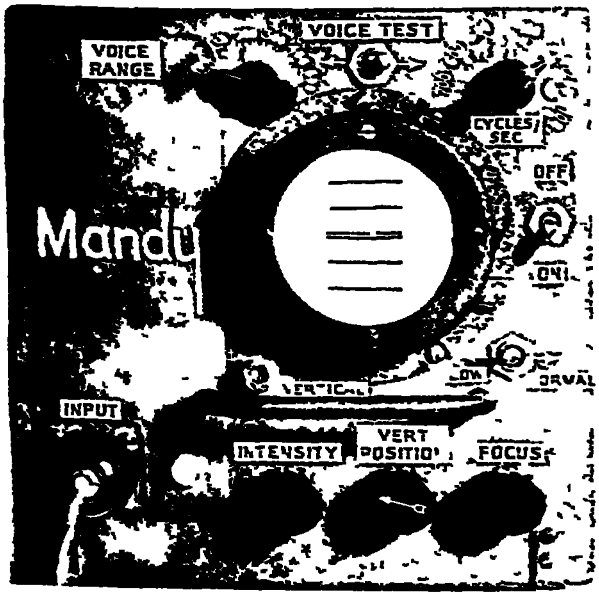

Fig 1—Front panel of voice trainer

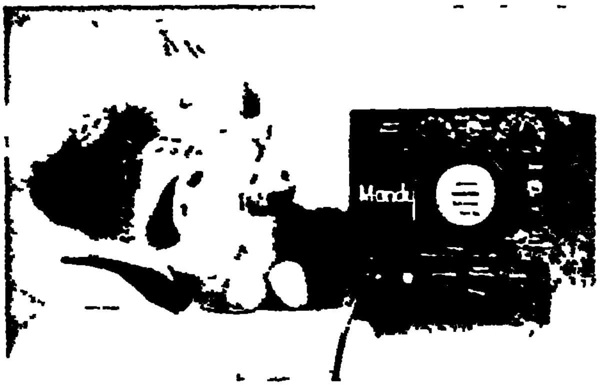

Fig 2—Child viewing voice trainer note collar bearing microphone on child s neck.

The front panel of the prototype instrument is shown in fig 1 and in fig 2 a child can be seen viewing the screen of the instrument in readiness for a voice-training exercise

The operation of the instrument is such that the effect of any extraneous noise is suppressed and the complex sound-wave generated by the child's voice is analysed so that only the fundamental frequency of the vocal cords is presented as a visual signal The child sees the pitch of his voice as a beam of light moving up and down the screen with the upward and downward variation of frequency, the beam disappearing when there is no vocal-cord vibration The controls of the instrument are set so that the chosen mean frequency above and below which the child is to vary his voice, appears on the central horizontal line on the screen, and the trials indicate that the frequency range demonstrated between the highest and lowest lines on the screen should be set at about an octave In fig 1 the instrument shows a mean frequency of 300 cycles a second, and in fig 2 a frequency of 400 cycles a second has caused the beam of light to move up the screen to a position between the two upper lines The prototype has been designed so that any part of the range of the human voice may be chosen, and it is therefore possible for men and women as well as children with high-pitched voices to use the instrument

So that the necessary funds may be raised to meet the costs of further tests and development before the final form of the instrument is determined for manufacture. a non-profit-making association, Speech Research for the Deaf, Ltd , has been incorporated, whose registered office is at 116–118, Chancery Lane, London, W C.2 The instrument is the subject of British patent application no 5569 57, and all rights for the invention have been assigned to Speech Research for the Deaf, Ltd Further forms of research will be undertaken as soon as the financial resources of the association reach a point where this is possible

I wish to thank Dr T S Littler, director, Wernher Research Unit on Deafness. for help and encouragement since the first prototype instrument was demonstrated to him last year

Medical Societies

ROYAL SOCIETY OF MEDICINE

Tetanus

THE Section of Experimental Medicine and Therapeutics and the Section of Neurology met jointly on May 13 with Prof J V DACIE in the chair

Prof G PAYLING WRIGHT reviewed the use of anti-tetanus serum (A T S) since its discovery by von Behring in 1890 In therapy, the antitoxin was soon found to be disappointing, but its value in prophylaxis was promptly recognised in veterinary surgery For man, it first showed its value on a mass scale by the striking fall in the incidence of tetanus which followed its general issue as a prophylactic agent among the wounded in the 1914–18 war

More recent studies on the persistence of injected A T S in children had shown that doses of 100,000 units (as used by Cooke et al 1943) probably maintained a protective level for six weeks, but the usual prophylactic dose of 1500 units (Bigler and Werner 1941) probably became ineffective after half that time

The hazards of anaphylactic reactions to a second injection of horse serum were well known, but the danger of "*tetanus post-serique*", which might result from prior sensitisation to horse-serum antitoxin and its consequent accelerated removal from the blood, was not sufficiently appreciated In studies on animals, Professor Wormall, of St Bartholomew's Hospital, had contrasted, with the aid of isotopic labels, the rates of loss of horse-serum gamma-globulin in normal and in previously specifically sensitised rabbits In the latter, a very large loss occurred even in the first ten minutes after fifty minutes only about a tenth was still in circulation Laws and Payling Wright had made similar experiments in 1952, using purified labelled bovine proteins in the previously immunised animals, little of the protein remained in the blood after twenty-four hours Laws later showed not only that these proteins were more rapidly removed from circulation but that they were also more quickly destroyed, because labelled polypeptides and other degradation products appeared more promptly in the urine

A probable instance of a failure of prophylaxis in consequence of previous "immunological education" to horse serum-proteins was the case of "*tetanus post-serique*" reported by Littlewood, Mant, and Payling Wright in 1954 A 14-year-old boy injured himself with an exploding home-made bomb and was given surgical and antibiotic treatment together with 1500 units of A T S Six months later, he again injured himself through another, almost identical, explosion and again received treatment together with 1500 units of A T S Twelve days later he developed trismus A trial dose of 0 1 ml A T S produced a general reaction, but eventually 100,000 units was given Despite treatment he died seventeen days after the injury The authors concluded that the prophylactic dose of A T S on the second occasion had been ineffective through its accelerated destruction They made two important recommendations first, that once A T S has been given to a patient, he should after a lapse of a few weeks be immunised actively with diphtheria and tetanus toxoid and second, that before any reconstructive surgery is carried out in a potentially tetanus-spore-infected area, a course of active immunisation should be given

Dr D R LAURENCE made the point that there was no general agreement on which drug was the most effective anticonvulsant, and this resulted in the polypharmacy with drugs of unknown potency commonly used in treating tetanus The ideal drug was one which abolished the convulsions but which did not interfere with respiration or seriously impair consciousness It was justifiable to use animals for testing the effectiveness of drugs because it had been shown that animals and man responded similarly to tetanus Local hind-limb tetanus was produced in rabbits by the injection of a small quantity of tetanus toxin, and electromyograms were recorded after a standard afferent stimulus in the form of an electrically operated tap to the frame supporting the animal The electrical responses from the muscles so obtained were electronically integrated and converted to arbitary units which were automatically counted Using this quantitative response it was possible to obtain accurate comparative bioassays of the anti-tetanus activity of many drugs It was found that the phenothiazine derivatives were much more potent than mephenesin Acetylpromazine was by far the most potent drug yet tested and it gave an activity ratio of 10 5, compared with chlorpromazine 1 0, promazine 0 46, and promethazine 0 32

A Bantu woman with local tetanus in her legs allowed similar studies to be made in a human subject using the stretch reflex as the stimulus It was shown that chlorpromazine and thiopentone both abolished the tetanus response, but even after thiopentone "emotional conversation" caused a return of the response but "sedative conversation" abolished the response This emphasised the fact that in the presence of fear and pain higher doses of drugs were needed to control convulsions

Although chlorpromazine had been used in anæsthetic practice since 1950, its selective anti-tetanic effects had probably been overlooked owing to underdosage and to the fact that it was never used alone Following the demonstration of its powerful anti-tetanic effect in animals Dr R E Kelly and Dr Laurence controlled severe tetanus spasms in a boy of $2^{1}/_{2}$ years with chlorpromazine alone by using high dosage Some authors had concluded that chlorpromazine was not of value because they used insufficient dosage Chlorpromazine was superior to and more convenient than mephenesin, but it was more toxic, and if doses were given too close together (more often than about every two hours) the effect of the drug was lost (*tachyphylaxis*)

Treatment of tetanus had so far been mostly unscientific Much could be learnt from animal experiments, but final assessment of a drug must be made by carefully designed clinical trials In no other way was it possible to measure whether one treatment was superior to another

Prof E B ADAMS summarised the results of the clinical trials which he and his colleagues had been carrying out at the King Edward VIII Hospital, Durban. Over 200 cases of tetanus in Africans and Indians had been seen in the past two years, and 171 had been included in two clinical trials In the first trial chlorpromazine was compared with barbiturates and in the second trial chlorpromazine was compared with a mixture of chlorpromazine and barbiturates No statistically significant difference was found between the results from the various treatments The mixture of chlorpromazine and barbiturates was easiest to handle and controlled convulsions well Lack of control was seldom a problem and death in convulsions was rare, but yet the patients died Necropsy seldom gave information, and pneumonia was not as common as might have been expected Intoxication of the medullary centres was very probably responsible When the period of onset was less than forty-eight hours the prognosis was bad, and this period was of more value than the length of the incubation period A caution against overtreatment of the mild or moderate cases was given, as they very rarely die and suffer a greater hazard from overtreatment

Dr HUGH GARLAND described the Leeds tetanus unit, which served a population of 3 million and had treated 18 cases of tetanus in the past three years Dr J J L ABLETT, anæsthetist to the Leeds unit, said that of the last 8 patients treated with positive-pressure respiration 3 had died He believed that tetanus "need not kill" They had had deaths from agranulocytosis, pulmonary embolism, and hæmorrhage Treatment with complete paralysis had lasted up to twenty-six days, with an average of two to three weeks Carbon-dioxide narcosis was an important hazard Dr W RITCHIE RUSSELL advocated tracheotomy even in cases of moderate severity, because the results were so good

Answering a question, Professor PAYLING WRIGHT deplored the withdrawal of tetanus toxoid as a prophylactic agent in child-welfare clinics In the discussion, Professor ADAMS said that if patients were kept alive for twenty-six days a 100% survival-rate was possible

Dr A CRAMPTON SMITH described the results of treating 7 cases of tetanus with complete paralysis 3 patients died, but this did not necessarily reflect the true mortality since the series was too small Mortality-rates in other series suggested that the overall mortality-rate from tetanus had declined in the past fifty years probably because of better nursing and general care, but severe grades of tetanus still had very high mortality-rates Curare had been used in the treatment of tetanus since 1860, but it was not until the poliomyelitis epidemic in Copenhagen in 1952 that it was found practicable to treat completely paralysed patients with continuous artificial respiration through a cuffed tube in the trachea The Danish workers first treated a case of tetanus by complete paralysis in 1953 At Oxford the patient with tetanus was first anæsthetised, then paralysed, an endotracheal tube was passed and respiration continued manually until the patient reached hospital, where a tracheotomy was done and a machine continued the respiration Difficulties arose because the patient could not breathe for himself, eat, or communicate He must receive continuous artificial respiration, be fed and turned, and his bronchi must be aspirated Electrolyte balance must also be controlled Every time he moved, a nurse gave an intramuscular injection of curare and hyaluronidase Considerable numbers of patients with various paralytic diseases had been treated in this way, including 32 cases of poliomyelitis with 7 deaths This treatment was expensive, and required large numbers of nurses It had been demonstrated, however, that patients with tetanus could be transported to a centre where they could receive the treatment that seemed to offer the best chance of survival Dr Crampton Smith suggested that this problem should be considered at a national level

Reviews of Books

Homosexuality

Its Nature, Causation, and Treatment CLIFFORD ALLEN, M D, M R C P, D P M, consultant psychiatrist, Dreadnought Seamen's Hospital, Greenwich London Staples Press 1958 Pp 143 15s

Live and Let Live

The Moral of the Wolfenden Report EUSTACE CHESSER, L R C P E London Heinemann 1958 Pp 126 8s *6d*

THE slow progress in disentangling the muddle of laws concerning sexual behaviour is discouraging Now that the Government are hesitating to implement the recommendations of the Wolfenden Committee, on the ground that they have no assurance of popular support for reform, it is to be expected that advocates will resort to the time-honoured practice of pamphleteering It does not detract from the high intentions and serious purpose of the authors of these books to consider their works mainly from the point of view of what they set out to do, and this seems to be to influence the public to move in the general direction advocated by the majority of the Wolfenden Committee These books share the good qualities of being well informed, interesting to read, persuasive without being irritating, and warmly partisan, but not to the point of insobriety They also share a common defect—each would have been very much more effective as two books

Dr Allen's difficulty is that he attempts, mainly by the use of case-studies, to encourage psychiatrists to take a more hopeful view of therapy and to convince patients that their condition can be alleviated These two goals are hard to attain in a single attempt, and the reader's sense of direction may be further confused because the book's aims are not explained until the final paragraph The homosexual patient emerges from the text as an unfortunate figure deserving at least a helpful approach by doctors, which, as many homosexuals know to their cost, is not always forthcoming Dr Allen raises the important question why homosexuals do not follow the much easier path of normal sexual behaviour but, instead, take a road which leads them into such terrible social, personal, and moral difficulties He attempts to show where the reasons may be sought, and his findings may bring hope to many sufferers

It seems a pity that the epidemiology of this condition is not examined more fully Why, for example, has Dr Allen included only 2 women among his 21 cases, and why does he appear to be thinking almost always of men and hardly ever of women? Both these questions illustrate phenomena of considerable importance and deserve fuller examination The book is not entirely free from some rather out-dated analytical modes of thought, manifest in a tendency to offer a stock explanation of common individual propensities For example, it is twice stated that the toddler child's dislike of rice pudding is related to his deprivation at the time of weaning The ordinary reader may well wonder about the author's knowledge of children because, since this oversimplification was first stated, there has grown up a generation of toddlers who know not rice pudding (because of the war) and who have been brought up by mothers with less restrictive notions both about nursery puddings and about insisting on their consumption The result of a nursery Gallup poll about rice puddings might show a majority in favour!

The difficulty in *Live and Let Live* is that Dr Chesser follows the lead of the Wolfenden Committee and attempts to deal with both homosexuality and prostitution at the same time The committee succeeded in keeping the two issues separate, but the same has not been true of the emotional and confused public discussions that have followed In taking both subjects together, Dr Chesser will scarcely add to clarity of thinking, because the "feeling tone" of homosexuality is so much stronger than that of prostitution, and this difference may make the second half of the book appear flat and forced compared with the first

Since his aim is to mould popular opinion and mobilise it in a "more rational" discussion of these problems, it is a pity that he does not consider more fully the significance of the enormous difference to be found, for example, in the strength of feeling shown by ordinary people towards male as compared with female homosexuality, and homosexuality as compared with female prostitution More understanding of these phenomena might make possible the more rational discussion that Dr Chesser and others so earnestly desire

The final sections of both of these books are devoted to constructive reviews of the Wolfenden Committee's proposals in relation to existing law, and they should do something to help secure the public acceptance of that mainly wise and humane report

Florence Nightingale and the Doctors

SIR ZACHARY COPE, F R C S London Museum Press 1958 Pp 163 21*s*

Miss Nightingale was a woman of complex character, who has been pictured in different ways by the several authors who have studied her Sir Zachary's book concerns one aspect of her life—her relationship with the medical profession He has examined it through the medium of her correspondence, diaries, and notebooks This material is voluminous (150 volumes are preserved in the British Museum collection alone), and much in the book has not previously been published Nevertheless, it must be an incomplete record of her activities, of which the most important part was often personal and confidential interviews of which no record survives

Miss Nightingale wrote to, or about, a large number of doctors—eminent and obscure, orthodox and "quack," British and foreign Some of her letters are to international figures, such as Sir James Simpson and Dr John Shaw Billings, others discuss a friend's choice of a family physician Two figures illustrate how her attitude to doctors depended largely on the man Dr John Sutherland, who was the chief medical member of the Government commission sent out to examine conditions in the Crimea, met Florence Nightingale there, and remained her staunch ally for 36 years Their joint efforts completely reformed the Army's standards of housing and sanitation They were the closest of friends—though Miss Nightingale did not scruple to write to him in severe terms if his opinions differed from her own Or to describe him as "a man without a soul" a few years before he died with, it might almost be said, her name upon his lips Very different was her attitude to Sir John Hall, the Inspector-General of Army hospitals Miss Nightingale attributed (perhaps unfairly) most of the evils she found in the Scutari hospitals to "his incredible apathy" And, as her notes of an interview with Lord Panmure prove, she was instrumental in curtailing his military career

To what qualities did Florence Nightingale owe her success? In an age when her sisters were striving for emancipation by emulating masculine activities, she achieved more than any of them She did so by using, to the fullest advantage, very feminine methods She was at pains to develop a warm friendship with many men in positions of high authority Once secure in their esteem, she seems to have used the threat of her displeasure to achieve the ends she sought, yet she was prepared to stay in the background and let the men retain the place of prominence She seldom attended meetings, or swayed large crowds, but she carried her points in private interviews, to which busy and influential personages were constrained to come by Miss Nightingale's rather dubious invalidity She was endowed with a shrewd intelligence, an uncanny gift for accurate and detailed observation, a clear grasp of the significance of statistics, and a tireless energy She was not, however, infallible, and to the end of her days she discounted all evidence which supported the theory of bacterial infection But, whatever her faults, the reorganisation of the Army Medical Services, the redesigning of scores of hospitals, and the introduction of an entirely new idea of sick nursing are lasting proofs of her greatness

Speaking of previous books about Florence Nightingale, Sir Zachary remarks that "few famous persons have been more fortunate in their biographers" That good fortune continue and Sir Zachary is to be congratulated upon a painstakin research that has cast fresh light upon the character of fascinating woman

The Human Ear Canal

ELDON T PERRY, M D, instructor in dermatology, Wayne Stat University Springfield, Ill Charles C Thomas Oxford Blackwell *Scientific Publications* 1957 *Pp* 116 36*s*

THIS very good monograph—mainly about external otitis—is well printed and excellently illustrated The overwhelmin impression it gives is that the human ear canal is a skin-line cul-de-sac and that any inflammation of the canal is, therefore an inflammation of skin—a fact that still needs wider recogni tion Dr Perry warns against the local use of antibiotics i most cases of external otitis, and he emphasises the error o regarding this condition as a single clinical entity, for th external auditory canal is subject to almost as many diseases a skin elsewhere, and each requires its own treatment

Few dermatologists or otologists will feel inclined to spend so much on a book that can be read carefully and comfortabl *in a single evening, but it should form a useful reference boo* in medical libraries

Surgery of Head and Neck Tumors

HAYES MARTIN, M D, associate professor of clinical surgery, Cornell University Medical College London Cassell 1958 Pp 430 137*s* 6*d*

THE first 100 pages are devoted to such general considera tions as preoperative and postoperative management, complications, and disabilities after operation, and there is a useful chapter on the risk of and the disability that follows the sacrifice of important anatomical structures After this, Dr Martin's book is essentially concerned with operative tech niques—imparted more by illustration than by text His book is therefore profusely illustrated, and some of the drawings are good It is less his intention to discuss the pros and cons of the procedures than to describe them nor does he attempt to assess the relative merits of surgery and radiotherapy, either as an adjunct or as elective treatment The value of the book lies in its statement of the methods now in use at the Memorial Hospital, New York

---

Industrial Toxicology (2nd ed Baltimore William Wilkins London Baillière, Tindall, & Cox 1957 Pp 376 $10)—The second edition of Mr L T Fairhall's book will be welcomed by many who are concerned with industrial medicine It has two parts, one on inorganic and one on organic substances In each part the toxic agents are discussed in alphabetical order, there are brief notes on the chemical and physical properties of each compound, followed by information on their industrial uses, toxicity, and methods for analysis, and a list of relevant references There are new chapters in which recent information on both pharmacology and toxicology has been incorporated The index is excellent There are one or two obvious omissions—for example, in the section dealing with cadmium, chronic poisoning is barely mentioned In general, however, the standard is high, and the book's usefulness is unquestionable

An Introduction to Pharmacology and Therapeutics (9th ed London Oxford University Press *1958 Pp 327 18s*)—Prof J A Gunn, with the assistance of Dr J D P Graham, has produced a new edition of his popular introduction to pharmacology It has been extensively revised and brought up to date, but with no great increase in length There is very little to criticise, but in the chapter on drugs affecting cardiac muscle quinidine receives rather scant attention, no mention being made of its important use in ventricular arrythmias, and procainamide is omitted altogether The book provides a sound, orthodox, and clear account of the actions of the more important drugs, and their uses, and it will be particularly useful to the student revising for examinations

THE LANCET

LONDON 24 MAY 1958

Malignant Hypertension

The discovery of ganglion-blocking and other potent hypotensive drugs has awakened hopes that with early diagnosis something might be done to check the fatal course of malignant hypertension The physician assessing the value of such drugs should know as much as possible about what happens to the untreated patient A yardstick of this kind has long been overdue, and accordingly a review by Kincaid-Smith, McMichael, and Murphy,[1] based on 197 cases of untreated malignant hypertension observed at Hammersmith Hospital in 1935–55, is particularly welcome In a disease which, left to itself, kills 55% of patients within two months of diagnosis and 90% within a year, the importance of premonitory symptoms cannot be overestimated, and the finding that, as the malignant phase approaches, headache becomes increasingly severe and common should be carefully heeded

The difference between the benign and malignant phases of hypertensive disease is now regarded by many as one of degree, but opinion has never been entirely unanimous This question hinges on the pathogenesis of the essential lesions of the malignant phase—namely, focal fibrinoid necrosis of terminal arteries and proliferative endarteritis of slightly larger vessels When Goldblatt's work opened up hypertension to experimental study it was soon found that these lesions did not occur in the kidney distal to the clamp on the renal artery[2,3] From this it was concluded that the lesions could not be caused by a circulating toxin, nor by simple ischæmia, nor by simple vasoconstriction due to a circulating pressor substance, but must in some way be related to the increased intra-arterial tension It seemed that the determining factor was a sudden strain imposed on the vessel wall by a combination of severe vasoconstriction and the accompanying rapid rise in blood-pressure This simple concept has stood up fairly well to the test of subsequent clinical experience and experiment. Lesions have been shown to follow sudden distension of the arterial tree, in animals by intravenous injection of saline,[4,5] and in man by operative relief of coarctation of the aorta[6] Necrosis has also been observed in the pulmonary arteries in mitral stenosis[7] By means of cranial windows the process has been followed in some detail in the brain of the hypertensive rat, and shown to be closely related to intense arterial contraction which disappears rapidly if the hypertension is abolished[8] The dramatic effect of lowering the blood-pressure has also been demonstrated in man[9] In their own material the Hammersmith workers find further corroborative evidence in the absence of arterial lesions from areas of kidney supplied by narrowed atheromatous arteries, and they do not dispute that the evidence shows that excessive intra-arterial tension can cause arterial necrosis Nevertheless they are unwilling to accept the conclusion that the arterial lesions in malignant hypertension are simple results of mechanical strain, and they seem to incline to a dual hypothesis according to which some toxic or even allergic injury, in addition to high blood-pressure, leads to " exudative angiitis "

A dual hypothesis of this kind of course implies that malignant hypertension must be regarded, not simply as a grade of severity which may develop in any sort of hypertensive disease, but as something differing in kind from the benign form, much more obscure and disturbingly akin to the primary nephritis with which it was so long confused In malignant hypertension fibrinoid necrosis can be found in afferent glomerular arterioles distal to interlobular arteries which are greatly narrowed by proliferative endarteritis The Hammersmith workers argue that hypertension can hardly be responsible for the former lesion, because the narrowing, like an arterial clamp, should act as a barrier But this assumes that the lesion in the interlobular artery precedes that in the afferent glomerular vessel There is in fact no evidence that it does It is more likely that the two lesions are responses to a simultaneous insult Similar narrowing of the lumen of interlobular arteries by simple or fibrinous exudate is commonly observed both in man[10] and experimentally, and endothelial proliferation is probably a stage in the repair of this exudative lesion There is no evidence to show how long fibrinoid necrosis in the more distal vessels can persist before repair occurs Kincaid-Smith et al find that, although the arterial pressure tends to be very high in the malignant phase, there are exceptions and the pressure is not impressively higher than in a control series of patients with benign hypertension In fact the mean difference in pressure in 25 matched pairs of patients with benign and malignant hypertension was no greater than 12 mm Hg But the control group was drawn from patients with retinitis, in whom, clinically and post mortem, there was no evidence of malignant hypertension Benign hypertension, on the estimate of the Hammersmith group, is about a hundred times as common as the malignant form, and it may be argued that the minority of patients with benign hypertension who come to post-mortem in a teaching hospital is, statistically speaking, a selected group which may include an undue proportion of severe cases The mean blood-pressure in this group was 213 mm Hg systolic and 122 mm Hg diastolic

The fact that in some patients very high blood-pressure may persist indefinitely without causing serious symptoms, while in others malignant symptoms appear before the pressure has risen to particularly high levels, does not invalidate the general proposition that malignancy is essentially an expression of severity In assessing severity in hypertensive disease it is necessary to consider not only the level of blood-pressure but also the intensity and nature of the underlying vasoconstriction[3 8] The available evidence suggests that the individual lesion in malignant hypertension owes its origin to a demonstrable functional abnormality which develops quite suddenly in overstimulated, overstretched arteriolar muscle, and if this essentially local disturbance is widespread or persistent enough the disease enters the malignant phase The fact that such a transformation is rare is perhaps remarkable, but no more so than the adaptability of arterioles in benign hypertension The simple physical concept of malignancy must of course remain tentative as long as so little is known about ætiology Nevertheless it may be unwise to reject it merely because it is simple, and still less because it is physical In the last analysis most if not all biological reactions are physical

Bones, Genes, and Pregnancy

ORTHOPÆDICS, though it has a long history, has been recognised as a surgical specialty only quite lately In Britain its birth is customarily dated from the work of HUGH OWEN THOMAS, who died as recently as 1891, fifteen years after KOCH's discovery of the cause of tuberculosis, and rather more than fifteen years before vitamin D was heard of Orthopædics in THOMAS' day was very different from orthopædics now Rickets was common, and its manifestations produced much of the surgeon's daily work Tuberculosis and osteomyelitis, not fully understood, wrought dreadful damage in joints and bones Poliomyelitis, then a mystery, led to contractures and crippling Injuries, apart from those induced by occupational hazards, were relatively few Since then orthopædics has seen a succession of dramatic changes Bone-grafting and bone banks have been established, and new materials introduced for pins, pegs, and prostheses Pyogenic infections of bones and joints have been trounced by chemotherapy and antibiotics, though it must be admitted that osteomyelitis is in some places staging something of a comeback, having called up its reserve forces of immune organisms Tuberculosis can now be treated very effectively, and it looks as though the days of poliomyelitis may be numbered On the other hand, the internal combustion engine has produced an appalling increase in the practice of traumatic surgery, and degenerative arthritis has become a greater problem in an ageing population

In all this change, one orthopædic responsibility has remained more or less constant The congenital deformities—club-foot, dislocated hip, and the like—which helped to give the specialty its name are still with us indeed, they are possibly more common because of the lower infant mortality and the better care of children Though the more striking genetically induced catastrophes have been documented, the commoner bony deformities need a great deal of further study But we are nowadays coming to realise that genetics is perhaps only part of the story By subjecting laboratory animals to stress during pregnancy we can now produce bony defects in the offspring just as surely as Nature can produce them by the union of two ill-suited germ cells This type of work is still in its infancy, and there is scope for a great deal of further effort

Last September the Société Internationale de Chirurgie Orthopédique et de Traumatologie, at its meeting in Barcelona, made this statement

> "In view of the serious problem presented by congenital deformities and the obscurity of their causation, this Congress recommends that its members should take the following action in their respective countries
>
> 1 To endeavour to establish research units in appropriate centres in collaboration with other interested workers, such as obstetricians, pædiatricians, and embryologists
>
> 2 To point out to their Governments the social and medical importance of the problem and to seek the financial aid necessary for the prosecution of research
>
> 3 When and where it seems desirable, to ask for the institution of statutory notification of disorders—rubella and diabetes for example—believed to be important in the ætiology of congenital disorders"

These propositions are in line with the modern idea of a concerted assault on a problem by the adherents of many disciplines—tactics that have already paid in many other medical fields Our knowledge of the processes involved in skeletal growth have matured very rapidly by following this prescription, and it is to be hoped that a similar result will attend the proposed attack on congenital deformities GREEN[1] has convincingly argued that more money and effort should be devoted to research in orthopædics, and there can be no doubt of the importance of this particular cause

Radioactivity and Public Health

Too often the subject of atomics is treated with the reverence accorded to a mystical cult, with the furtiveness appropriate to industrial restrictive practices, or with the secrecy which national security may or may not require Yet what we are witnessing is perhaps the greatest ecological change since the recession of the polar icecap at the end of the last Ice Age Even the small amount of research already done has demonstrated the selective uptake of radioactive isotopes by certain aquatic and terrestrial plants, the varying sensitivity of different forms of life to increasing radiations, the biological concentration of some isotopes in the tissues of the animal body, and their effect on genetic mutations We are standing on yet another fringe of the unknown, not as Man alone, but with the whole range of living things grouped around us in a symbolic question-mark It is against this enormous background that we have to examine our more local problems of radioactivity

---

[1] Green, W T *J Bone Jt Surg* 1957, 39A, 675

The decision of the Liverpool City Council to buy apparatus for measuring radioactivity in their water-supplies not only illustrates the movement of local authorities into this new territory but also raises wide issues—what and why and when and how and where and who? In Liverpool the city council are cautious in feeling their way into atomics, but they think that the time has now come to build up a mosaic picture of radioactivity as it may affect their population—to establish their datum line of background radiation levels, to watch for the changes and record the facts, and to check the food that the people of Merseyside eat, the air they breathe, the water they drink That project will carry their investigations far afield, for their present water-supplies come from Wales and Lancashire, and their future schemes include using the River Dee as an aqueduct, with all the extra possibilities of radioactive industrial effluents There is, of course, nothing novel about far-flung interests Manchester keep check on their Lake District reservoirs at Thirlmere and Haweswater, and other large water undertakers take the same precautions There is nothing novel about abstracting water below the outfalls of potentially radioactive waste much of London's drinking-water is taken out of the Thames below the outfalls of the Harwell, Aldermaston, and Amersham atomic establishments The novelty lies in the growing emphasis on the need for independent control, and the need to come to terms with changing ways of life

In the matter of ways and means, it is clear that though some of the larger municipalities, to discharge their responsibilities, may create comprehensive radiochemical and radiobiological laboratories, such action will be far beyond the resources of the majority Probably the time is not far distant when all public-health authorities will be expected to maintain routine monitoring in their districts, but qualitative analyses are not so easy, and interpretation of the factual data can be harder still Perhaps the larger municipalities will extend their facilities to their neighbours, both for the analytical work and for interpretive advice—provided they can attract staff of high enough calibre to hold consultant status But there are possible alternatives For example, the public analysts may see in atomics a fresh opportunity for expanding their professional business, particularly in the commercial markets Specialised agencies for providing radiological protection have already entered hospital and industrial practice, and they seem likely to increase in number and value The universities, on the other hand, should avoid becoming too far involved in the routine work of the extramural world, and it would not be sensible to look to them to provide the services required

The United Kingdom Atomic Energy Authority occupy a unique position They certainly have the equipment, the laboratories, the concentration of knowledge, and the specialist staff required for their own purposes, but just how far they can be expected to offer help outside their perimeter wire is still debatable They are still hypersensitive about their safety obligations under the Atomic Energy Act, they remain much preoccupied with their own industrial medical service, and they are feeling their way in public relations Acting on a recommendation by the Fleck Committee, they have now appointed a committee, under Sir DOUGLAS VEALE, to advise them on the training and provision of "health and safety" staff not only for their own purposes "but also to meet the needs of the nation as a whole" (see p 1137), but it would be unrealistic to expect an adolescent industry to undertake unlimited commitments Though they have agreed to make their resources available to some of the smaller public-health authorities in the vicinity of reactor establishments, obviously there must be a geographical limit, both for the A E A to foster good personal contacts, and for the public-health authorities to expect the A E A to provide a free monitoring service Again, while it is reasonable to expect cooperation from the A E A in monitoring their own effluents, and to help in estimation of natural background levels and fallout effects, they could hardly be asked to supervise the radioactive wastes from other industries, hospitals, and laboratories in the area The public-health authorities will rightly be expected to do what might be called their own dirty work

The increasing industrial use of radioactive isotopes opens up another possibility for routine supervision Various Ministries already have monitoring responsibilities under the Atomic Energy Act, and some have appointed a radiochemical inspectorate Expansion of those departments, with their possible absorption into the Factory Inspectorate, would be one way to provide nation-wide monitoring But this might well mean that attention was concentrated on the industrial problems of radioactivity, whereas we should be thinking of the total load of radioactivity, from whatever source If, for this reason, it is accepted that the public-health authorities are the proper bodies to keep a watchful eye on the health and safety of the whole community, might it not be better if the expert help they will need were given by the Public Health Laboratory Service, so long a valuable companion to the medical officer of health in his day-to-day epidemiology? The personal contacts are there, the confidence is there Opinions differ on the future of the P H L S[1], but if it is to remain outside the National Health Service it could logically be extended by adding a radiochemical section Specialist staff could hardly be assigned to every laboratory, but some convenient regional grouping might be possible, as with some other specialised techniques Quantitative measurements, qualitative analyses, and interpretation could alike be made with a bias towards the practical work of the public-health authorities, whose cooperation would be implied, and whose duty to safeguard the public health in this as in its other aspects would remain as clear as it is strong

Annotations

LIBERTY, EQUALITY, AND HEALTH

OVER the years opposition to health legislation has been steadily weakening and falling back on untenable positions Its deepest ditch has always been that health measures curtail the freedom of the individual In an interesting review of the organisation of medical care during the past fifty years Prof R M Titmuss[1] suggests that even this is based on a misconception The summits of health legislation in these years were of course the Acts of 1911 and 1946, and in his view both of them only substituted one form of collectivism for another and each offered increasing freedom to a growing circle of doctors and patients

The development of scientific medicine since the beginning of the century, accelerated by two world wars and what Professor Titmuss describes as the scientific discovery of malnutrition in the 1930s, made the reorganisation of medical care inevitable Advances, which were swift and seldom simple, ranged from new fundamental concepts such as the new ideas of Freud to complicated techniques of the laboratory and operating-theatre, and to potent new drugs Their complexity made specialism a necessity Their cost raised problems of distribution that were thrown into sharp relief by new statistical and social methods which showed the inequalities of health among different groups of the population Emphasis began to shift from the environment to the individual patient, from the public-health officer to the general practitioner, though general practice at the time was in a sorry way Professor Titmuss estimated that in the days before the panel only 10–20% of the population were able to afford to have a private doctor for the whole family For the rest of the population there was club practice for the breadwinners The women, children, and old people had to make do with the outpatient departments of the voluntary hospitals, the poor-law institutions, and the sixpenny doctors One unhappy result of this sporadic medical care was people's reliance on the " secret remedies " which turned many of them into " permanent medicine swallowers ", a national habit which, as we know to our cost, still persists

Contract practice, in Professor Titmuss' view, was also one of the chief reasons for the doctors' distrust of lay administrators which was shown in their negotiations with the Government in 1911 and in 1946 Indeed the present structure of the National Health Service, he suggests, owes more to the opinion of doctors than to political and public opinion As he assesses the situation, in 1945 many of the consultants, foreseeing the coming bankruptcy of the voluntary hospitals, the threat of greater local-government control, and the probable harmful effects for doctors as well as patients of the rise in the private costs of health, shrewdly led the profession into the National Health Service However that may be, the Act of 1946 extended health enfranchisement to women and children and the middle classes Professor Titmuss considers that the service would perhaps not have been so comprehensive but for the nation's post-war mood for justice and equality of opportunity But it was also, in his view, a renewal of the argument for the freedom of doctor and patient To see it solely as a collectivist device for the benefit of the working-classes is too simple, and he believes that the middle classes have benefited even more, and the doctors most of all

GOING TO HOSPITAL WITH MOTHER

THE children of this country are ill less often than ever before in our history But for the many who still fall seriously ill what is the best type of care to provide? Wider recognition of the emotional sufferings of little children separated from their mothers has led thoughtful doctors and nurses to promote various reforms Elective operations can be postponed until a stay in hospital is a less disturbing experience for the child—that is, until he is over the age of 5 or 6 Daily or unlimited visiting is becoming much more common in children's wards Mothers are now sometimes admitted with their young children, and, finally, more illnesses are being treated in the home

The first film made by Mr James Robertson, of the Tavistock Clinic, *A Two-year-old Goes to Hospital*,[1] helped to draw notice to the need for these improvements This moving picture of a young child's suffering in hospital caused a painful emotional struggle in many people, who had to recognise that their conscientious efforts to help had caused avoidable suffering When Mr Robertson's second film, *Going to Hospital with Mother*, was shown to a Press audience a few days ago it was preceded by excerpts from his first film, and the juxtaposition emphasised convincingly the contrast between the emotional states of two young children admitted to hospital for the same operation For the second film is of a mother and child entering the children's ward of Amersham General Hospital, where nearly half the under-5-year-olds are accompanied by their mothers Making allowance for differences in temperament, there can be no doubt whatsoever that the little child who had her mother with her overcame a more serious physical reaction to the operation with far less emotional disturbance than the child whose mother could spend only a short time with her each day Even the most sceptical audience could hardly fail to be impressed by this second film, which is technically of a high order and well constructed to convey its message

But bringing mother into hospital with the child is not enough in itself The film makes clear that a big change of attitude is called for—particularly in the nursing staff In a ward where mothers and children are admitted together those in charge must be able to appreciate the mother's anxiety and to help her with it Not only has the mother an ill child to worry about, she has had to leave her husband and possibly other children to fend for themselves She may also have conscious or unconscious anxieties herself about hospitals, and medical or surgical procedures This maternal anxiety can, and does in certain cases, communicate itself to the child or other mothers But, provided the mother can be given understanding support, there is no doubt that the child will benefit greatly from her presence and comfort at a difficult time The mother will, at the same time, gain confidence in her relationship with her child, through encouragement to help him when he is ill and needs her most

The ward-sister who can find satisfaction in helping mothers to help their children is unfortunately still too rare, though if more doctors were far-seeing enough to give the lead hidden reserves would surely be uncovered But a wholesale change in the attitude to childhood illness could not be achieved without changes in the training of nurses and doctors It is the nurses who fear most that they will lose their function, yet in fact the way is being opened for them to play a much bigger part in the lives of their patients

[1] A lecture on health, in a series on Law and Opinion in England in the Twentieth Century, given at the London School of Economics on April 29 The series will be published later under the general editorship of Prof Morris Ginsberg

[1] See *Lancet*, 1952, ii, 1122

Thinking beyond the lesson of this film, we can recognise that many more young children who are ill could be nursed at home, given adequate special assistance Most mothers would probably be much less anxious in their own homes, where they can be helped to fulfil their many responsibilities without a conflict of loyalties Clearly it is least disturbing emotionally for the sick child to have no extraneous difficulties, such as separation from home or mother illness itself is enough of an anxiety

Moreover, from the physical viewpoint, hospitals are by no means always the best places in which to be ill at any age Perhaps Mr Robertson will make another equally skilful and convincing film called *Being Ill at Home*?

THE ASIAN INFLUENZA EPIDEMIC

LAST week the Section of Epidemiology of the Royal Society of Medicine discussed the recent world-wide epidemic of influenza Dr A M -M Payne, of the department of endemo-epidemic diseases of the World Health Organisation, described the surveillance of last year's epidemic, the first widespread epidemic to arise since W H O set up a network of laboratories and listening-posts for an eventuality of this kind By a curious stroke of fate, however, the epidemic started in Communist China, which is not a member of W H O As a result, two or three valuable months were lost before W H O could give warning that a new influenza virus was about and that it was likely to spread and cause epidemic disease Within seven months the new virus had spread to almost every country in the world, and in many places attack-rates of 20–40% of the population were reported Overcrowding had a striking effect in increasing the attack-rate, and almost everywhere it was found that people over 60 were less likely to be attacked than younger people There has been much speculation whether this sparing of older people might be the result of infection in earlier life with a virus immunologically similar to the present Asian virus[1], but the feeling of many who took part in last week's discussion was that older people were less exposed to infection

This point was carefully discussed in a thoughtful paper by Dr J C McDonald, who summarised a series of investigations of the epidemic in this country There was a striking association between the onset of an epidemic focus and the opening of schools in that area Schoolchildren then brought the infection home, as was easily shown by study of the onset of primary and subsequent cases in families There was a lower incidence of influenza in families without schoolchildren, and if families without children were considered alone there was no sparing of older people compared with younger members of the same family Taken together these findings suggest that older people were spared because they were less exposed to infection There is growing evidence, however, that although older people were relatively free from influenza during last autumn when the epidemic wave was at its height in this country, infections with the same virus were continuing during the early part of this year Deaths probably due to influenza showed two peaks, one in the autumn and one in the early part of this year, and, in the second wave particularly, there was a high proportion of deaths in those over 65 The influence of weather and the significance of the sparing of older people during the first wave remain important subjects for investigation

On the key question, "What will the Asian virus do next winter?" both Dr Payne and Dr McDonald thought that after this burst of activity it would now settle down to a normal existence

SUDDEN BLINDNESS

ONE of the less common emergencies that face the neurosurgeon is sudden visual failure, either in one or, occasionally, in both eyes The diagnosis between surgically operable and other conditions may not be easy, while it is notorious that tumour within the sella turcica may give rise to a bizarre picture that is usually mistaken for meningitis, subarachnoid hæmorrhage, or sagittal-sinus thrombosis In a helpful article Uihlein and Weyand[1] analysed the causes of unilateral loss of vision of 310 cases at the Mayo Clinic Ophthalmological conditions accounted for 50% of the cases, while in 39% there was a lesion involving the retrobulbar portion of the optic nerve Uihlein[2] reviewed those cases in which there was acute visual failure and found that the non-ophthalmological causes were, in order of frequency, pituitary tumour, glioma of the optic nerve or chiasma, aneurysm, "parasellar lesion", carotid thrombosis, distension of the third ventricle by hydrocephalus, chiasmal arachnoiditis, fracture of the anterior cranial fossa, tumour of the base of the skull, and pseudo-tumour cerebri The most important of these is the commonest—pituitary tumour The effects of pituitary tumours include acute complications,[3] of which the most dangerous is "apoplexy of the pituitary gland" In this, Brougham et al[4] found that extensive necrosis or hæmorrhage in a pituitary adenoma resulted in the sudden onset of drowsiness followed by stupor or coma, severe headache with nuchal rigidity, ocular palsy, and sometimes amblyopia or hemiparesis The cerebrospinal fluid contained blood or was xanthochromic with an increased number of white blood-cells and commonly an increased amount of protein Indications of pituitary insufficiency may be the only early feature distinguishing the disorder from acute adrenal insufficiency, a temporal-lobe pressure cone, or the effects of an epileptic convulsion Even after investigation in hospital, cavernous-sinus thrombosis, meningitis, or subarachnoid hæmorrhage may be reasonable diagnoses The condition is extremely dangerous, and saving of life is the first consideration As long as the clinical course moved towards recovery, Brougham et al pursued conservative treatment They suggested that with adequate supportive measures some patients might reach a plateau of improvement from which some of them might be rescued List et al[5] described three cases of a similar syndrome with a satisfactory outcome They recommended operation provided there was no hypopituitarism, but if severe panhypopituitarism dominated the picture early surgical treatment was inadvisable Even diagnostic procedures may lead to sudden peripheral vascular collapse Investigations should include blood-sugar curves and estimation of electrolytes A ventriculogram may furnish valuable information[6]

[6] Jefferson, G *Proc R Soc Med* 1940, 33, 433

Discussing the causes of acute visual failure, Uihlein described five cases in which visual improvement followed prompt operation As long as any vision at all remains, surgery may offer considerable hope of restored vision Where complete blindness has resulted the prognosis is so much worse, but even then vision may occasionally be restored by prompt intervention Where blindness is accompanied by acute hypopituitarism the risk must be carefully weighed, and the neurosurgeon's judgment is stretched to its utmost

ANÆMIA DUE TO ANTICONVULSANT DRUGS

In 1954 Badenoch [1] demonstrated megaloblastic anæmia in 2 epileptic patients, and Hawkins and Meynell,[2] reporting a similar case, suggested that the phenytoin ('Epanutin') given for treatment to all 3 patients was the cause Later in 1954 Chalmers and Boheimer [3] described a similar incident in a patient who had had barbiturates and phenytoin for some years but for the previous six months had had primidone ('Mysoline') Since then several cases have been reported, and isolated reports continue to appear for example Kidd and Mollin [4] reported a case associated with phenytoin and another with phenytoin and primidone treatment, and Barker [5] and Varadi [6] have lately reported further cases in our columns Newman and Sumner [7] reported a case associated with primidone but reasonably concluded that megaloblastic anæmia due to anticonvulsants is a rare complication that should not deter physicians from using phenytoin and primidone, now the two most effective anticonvulsant drugs These reports make it important to find out the true incidence of megaloblastic anæmia in patients with epilepsy receiving anticonvulsants, whether there are any early indications that the drugs are causing interference with hæmopoiesis, whether such signs can be corrected, and, if so, whether this benefits the patient

To answer such questions, Hawkins and Meynell [8] have carried out a series of investigations in a colony for epileptic and mentally defective patients

They studied 72 epileptic patients (40 male and 32 female) who were all receiving anticonvulsant drugs—phenobarbitone, phenytoin, and primidone, alone or in combination For controls they used 30 non-epileptic mental defectives living in the same colony, and 30 healthy persons, mostly medical students and hospital staff Few patients were actually anæmic, but significant macrocytosis was found Of the epileptics a third had a mean corpuscular volume (M C V) of 94 c μ or more, and the mean in all the epileptics was 92 2 c μ (S D =4 51), whereas in the normal controls the mean was 86 6 c μ (S D = 2 53) In the 30 patients who lived in the same colony but did not have epilepsy the figure was 88 7 c μ (S D =2 58) All these differences were statistically significant Further analysis showed that of patients receiving both phenobarbitone and phenytoin, 45% showed macrocytosis of the erythrocytes, in patients on one drug the figure was 34% for phenobarbitone and 27% for phenytoin, 2 out of 3 patients on phenytoin and primidone had macrocytosis, but all 4 on primidone alone were normal There did not appear to be any significant dietary deficiency among the patients, and there was no evidence of liver disease The incidence of macrocytosis was unrelated to the number of fits

There was indeed little doubt that the anticonvulsant-drug therapy was the cause of the macrocytosis Hawkins and Meynell investigated the serum-vitamin-B_{12} levels in a group of epileptic patients and found normal figures, they took 6 with macrocytosis and gave them 100 μg vitamin B_{12} subcutaneously weekly for two months, but the macrocytosis remained unaltered There was therefore no indication of vitamin-B_{12} deficiency Tests to determine effects of folic-acid absorption or tissue depletion of folic acid were carried out by Girdwood's method [9] and no abnormalities were found But when 20 mg of folic acid a day was given orally for a month to 6 patients with macrocytosis, the M C V values fell towards normal in every case

Actual drug-induced macrocytic anæmia is, as suspected, uncommon Hawkins and Meynell had been studying 170 epileptic patients over two years and found only 8 cases of macrocytic anæmia among them

6 of the 8 were being treated with a combination of phenytoin and phenobarbitone, 1 was on phenytoin alone, and 1 on primidone and phenytoin In 4 the anæmia was severe, with hæmoglobin levels from 22% to 47%, and all these patients had typical megaloblastic marrows, of the others 2 were reported as macronormoblastic and 1 as "hypoplastic", and 1 was not examined

Their patients were given vitamin B_{12} and, as in other trials, the response was variable, 5 of the 8 patients responded well, but 3 needed folic acid The anticonvulsant drug was kept on at the same dose except in 1 patient whose phenytoin was stopped and phenobarbitone given instead Folic acid seems to be the most suitable anti-anæmic drug, and Hawkins and Meynell suggest that a daily dose of 5–10 mg provides sufficient protection, with this dose there has been no tendency for neurological complications to appear

Hawkins and Meynell draw attention to the remarkable improvement in the epilepsy when the anæmia was treated, and their case-reports are indeed striking

For example, a man who had previously had 2–3 attacks of minor epilepsy a month for twenty years had no further attacks after treatment of his anæmia and maintenance on folic acid for three years, and a man aged 21, who had at least 3 major attacks daily, has had a two-year period free from attacks after treatment of his anæmia On the other hand treatment of the anæmia had no effect on the number of fits in an imbecile epileptic

Hawkins and Meynell hold that "blocking of vitamin B_{12} and folic acid is an important factor in lowering the threshold for the cerebral discharge producing the epileptic attack" This blocking presumably interferes with the synthesis of ribonucleic acids—and at an early stage in the process, according to current views, since vitamin B_{12} and folic acid can overcome the effect

From a practical point of view this report shows that it is worth examining at regular intervals the blood of epileptic patients who are receiving regular treatment with anticonvulsant drugs To detect the toxic effect in its early stage, it is necessary to estimate the mean corpuscular volume This estimation is carried out in most laboratories by Wintrobe's method, which involves taking a sample of venous blood Some methods require only finger-prick blood, for example, Shils et al [10] have described a micromethod using the usual 0 02 ml "hæmoglobin" pipette, and such a method might be more convenient in an epilepsy colony If the M C V is high and continues to rise, treatment with folic acid in addition to the anticonvulsant is indicated Since the epilepsy itself benefits from the correction of the anæmia, regular ordinary blood-counts should also be part of the programme of control

EARLY DISORDERS OF THE MOTHER-CHILD RELATIONSHIP *

FREDERICK H STONE
M B Glasg , M R C P , F R F P S
CONSULTANT IN CHILD PSYCHIATRY,
THE ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW

THE importance of early childhood experiences in the genesis of psychoneuroses in adult life is widely recognised and indicates where the first steps should be taken to prevent such emotional breakdown The child-guidance clinics, overworked and understaffed, complain that even their cases often come too late So we turn to the very earliest years of life and already find, although our clinical experience in "*infant psychiatry*" is not yet extensive, much to interest those concerned with the health of children

Normal Mother-child Relationship

The mother-child relationship may be described as the sum total of the thoughts, feelings, attitudes, and resultant behaviour of a mother towards her child

Where human psychology is concerned, "normal" is almost a forbidden term, yet some attributes of mothering seem to be of its essence, though taken so much for granted that we become aware of them only when absent or distorted Although most of these are relevant for the whole range of childhood, the emphasis shifts with increasing age

Firstly, and basically, there is mother-love, to which an essential corollary is the mother's enjoyment of her child Next there is protectiveness of the child from psychological and physical traumata Although a mother's mood may fluctuate within fairly wide limits, there should be an underlying consistency of attitude We do not expect what is forbidden on Monday to be condoned on Tuesday

A mother's reactions should be appropriate to a given situation, and we are startled when confronted, for example, with real amusement as a response to a child's severe distress A mother should perceive her child as a separate person, she should not make the child simply an instrument of her own ambitions (Stone 1955)

Disordered Mother-child Relationship

As soon as we attempt clinical description, it is proper to ask what is known of the normal range of interactive behaviour between mother and child It must be emphasised that this is not the same as the "milestones" of child development Without in any way disparaging the pioneer observations of Gesell and others in this field, we can say that these workers studied the developing child, as it were under a psychological microscope but to a large extent in vacuo, with little reference to the development of the child's primary interpersonal relationship with its mother

It takes assiduous practice to be able to observe, let alone record, everyday interaction between mother and child (Escalona 1953) such as confronts us daily in clinic and consulting-room, but which we tend to ignore as irrelevant

DISTURBANCES IN EMOTIONAL CONTACT

Lack of Contact

Mother and child are together yet remain two separate unrelating people The toddler is exploring the surgery or examining some toys, and the mother is telling her story to the physician, but nothing happens between them This is quite abnormal, even for a worried mother in a strange setting, because ordinarily the more threatening the environment the more perceptive is a mother of the minimal distress signals emanating from her child Interruptions and distractions are the rule The appeals to the mother to "see what I've done", to "lift me, I'm tired", to "take me to the bathroom" are often conveyed by minimal cues, even without words, but, just as a mother responds even while asleep to the infant's first whimper, so here the maternal antennæ pick up the distress signals and take appropriate action

The picture has a different look where a mother and infant are concerned (Levy 1951) Here we are inclined to describe what we see figuratively—e g , "That woman handles her baby like a parcel" By this simile we record the absence of a whole range of maternal activities which ordinarily are in action Even during a consultation the mother will make her infant more comfortable, address it, smile at it, soothe it to sleep, and so forth In the absence of all this the child seems to have an inanimate quality—"like a parcel" This impression of "emotional distance" is sometimes strengthened by the mother's avoidance of the use of the child's name or the more common "he" or "she", instead she may refer to "it"

Excessive Contact

By contrast we have a situation in which for long stretches of time there is never a break in contact This is the mother who, even as she is talking to the physician, is all the time touching, caressing, fondling, stroking, or hugging her child, but automatically and not in response to the infant's actions, almost as if the child were a pseudopodium, an extension of her own body (Escalona 1948) Sometimes when one is listening to her story, it is quite difficult to tell whether she is describing the symptoms of the baby or of herself

DISTURBANCES IN PROTECTIVE FUNCTIONING

Excessive Maternal Anxiety

This mother is convinced that there is something wrong with her infant and, despite repeated negative clinical findings and abundant reassurance, persists in her belief Her complaints tend to be vague or subjective, her infant may be thriving, but her intense anxiety is real enough, and in search of help she migrates from family doctor to health visitor to pædiatrician and back again

This is not just an anxiety state in a woman who happens to be a mother, for her anxiety is focused exclusively on her child It should be remembered that maternal anxiety is a normal component of the protective function and only when it becomes inappropriate in degree or context should it be regarded as pathological The assessment of this situation calls for the keenest clinical acumen, and most of us have encountered just such a case where a mother's intuition in the end proved superior to expert opinion

In reaching a decision one must balance carefully the data provided by sensitive history-taking, an assessment of the mother's personality, and a careful physical examination of the child Once again the disorder can often be diagnosed by observing the mother's handling of the child We may describe this as follows "You would think her baby is made of porcelain", or "She holds it like a fragile doll", as if it might break in her hands This behaviour persists, unlike the uncertain tentative handling by the mother of her firstborn When the child grows a little older, we begin to see the widely recognised picture of maternal overprotection, where the mother anticipates every possible and impossible danger, is oversolicitous about the child's health, tends to overfeed, and so on

---

*Based on a lecture given to the Scottish child-health group of the Society of Medical Officers of Health in February, 1957

Lack of Protective Functioning

It is rare to witness this deficiency in crude form, but at times one encounters a child who is constantly exposed to physical dangers—fire, open windows, traffic, and so forth A less obvious variant of unprotectiveness, however, is not so rare failure to protect the child from its own overwhelming emotions—e g, the mother who allows mounting rage to proceed to a stage of panic, who demands standards of performance well beyond the child's maturity, who uses terrifying threats and warnings or exposes the child to scenes of violence

During a consultation a mother observed in the presence of her 6-year-old son "Of course he's an adopted child", and in response to my query she answered "Oh no, he doesn't know anything about it" This, by the way, was not a stupid woman Indeed, I have found little evidence to suggest that the mother's level of intelligence is a significant factor

Sometimes a mother makes almost adult demands of her baby "I have always laid great store by encouraging the child's independence In fact I have always trained her to make her own decisions As soon as she could talk, at 15 months, I would make her decide at breakfast whether she wanted her egg boiled or poached"

Another striking instance of disordered protective functioning was the mother whose 2-year-old daughter was so pale (largely because of a feeding problem) that the mother always put rouge on the child's cheeks before taking her out for a walk

Reactions of the Child

Sometimes the child does not seem to react to these disorders in relationship For example, in routine baby or toddler clinic examinations our own observations of maternal attitude and handling may strongly suggest that all is not well, yet the mother has no complaints, and the child is in excellent health and spirits Later we may find that another child in the same family and under very similar conditions is far from well It should not surprise us too much that infants are born with different degrees of sensitivity to emotional stimuli, the occasional child reacting violently to minimal stresses Glover (1953) has rightly made a plea for careful follow-up studies of these infants, postulating that these behaviour patterns may be the very first hints of psychological instability

In other cases where there is clear evidence of disordered mother-child relationship the child's "symptoms" may be entirely subjective, at any rate at first, but sooner or later the baby tends to show disorders of crying, of sleeping, of feeding, and of bowel function, alone or combined The child may cry all the time or not at all, refuse to sleep or sleep excessively, show no interest in food, vomit or ruminate, or have bouts of diarrhœa Where an allergic diathesis is present, the response may take the form of infantile eczema or "wheezy bronchitis" There is great difficulty in diagnosis here in that these symptoms may also present in a large range of medical and surgical diseases of infancy The attempt, however, should always be made to diagnose a disordered mother-child relationship by recognising its positive signs and not to infer the diagnosis by failing to detect clinical signs in an infant The presence of such signs may not be the cause of the symptom in question, their absence may only mean that the lesion is clinically undetectable At a slightly older age other responses appear—e g, temper tantrums, breath-holding attacks, withholding of fæces, and excessive and persistent fears

Technique of Interview

At least half an hour is required, and for the physician recording both the spoken word and behaviour it is a busy half-hour Minimal direction is given because so often the apparently irrelevant may be highly significant Moreover—and how many of us are ever taught this as students?—obvious omissions, evasions, and contradictions should be recorded If in history-taking one is repeatedly frustrated in trying to obtain consistent information about one particular topic—e g, the pregnancy or the feeding situation—it will afford little, to press harder for an answer, and nothing at all if the questioner is by now exasperated Of course, a certain degree of orderliness is essential in the gathering of a history, but this is not in any way incompatible with a non-directive technique

Essential in the interviewer is a sympathetic attentive listening attitude There is here a special difficulty for the contemporary physician All his training from undergraduate years onward has groomed him for a role of action He is expected to make decisions, to advise, to prescribe Now, disconcertingly, he is required to adopt ah essentially passive role In the face, perhaps, of a singularly unmanageable child and completely ineffectual mother he must remain not only a passive observer but also a relaxed one Some can never hope to achieve this, but for the majority the most effective aid is determined concentration on the task of recording what is happening The physician must listen sympathetically without judging, criticising, advising, or becoming emotional himself, but giving his full attention Even a very little proficiency in the technique of the psychotherapist (for that is what is being described) will expose the interviewer to an even trickier hazard—the attitude of the parent towards him

The physician may be surprised to discover that the adoption of these few modifications in interviewing technique often produces a rather startling response, and by no means invariably a friendly one Whether the parent's response is one of dependency, gratitude, hostility, or rivalry, it will almost invariably appear so exaggerated in intensity as to seem inappropriate to the clinical situation An explanation of these transference phenomena is not within the scope of this paper, but their understanding is important and can be achieved only by discussion of the cases with a trained psychotherapist And still the physician must remain interested, sympathetic, and undismayed

A first interview emotionally charged in this way should invariably end with the offer of a second appointment, which may develop into a series of interviews To the distraught parents this is the concrete evidence that here is a doctor who accepts them, “ badness and all ” A first interview held jointly with both parents and child is of such rich potential that it is surprising how methodically many child-guidance clinics eschew its use It must be very seldom indeed that a child hears in a consultation anything said about itself which is half as frightening as it has already constructed in its own imagination

Ætiology

There can be little doubt that events in pregnancy can contribute to later distortions of the mother-child relationship (Caplan 1951) We are all aware of superstitions and old wives' tales connected with pregnancy, and any one of these is a potential source of danger to an expectant mother Curiously, these appear to operate universally, irrespective of intelligence, education, or social class Each culture has its own favoured beliefs, but none is free I do not suggest that, because an expectant mother has had mixed feelings about a pregnancy or has worried a great deal about some thought or action, a disturbed mother-child relationship must inevitably follow This happens only when the event becomes coloured with guilt It is almost certainly true that the core of the disturbance really belongs to a much earlier point in the mother's emotional development, and that this is “ triggered off ” by a psychic event during the pregnancy

A boy, aged 2½, had violent temper outbursts on the mildest provocation As a baby he cried all the time, and brought up his bottles His brother, ten months older, was well The mother spontaneously described the circumstances of her father's death which occurred during the early months of the pregnancy He was in hospital and she was asked to take him to her home Instead, she persuaded another relative to do this, did not tell the truth about his condition, and he died within a week The baby was unwanted, and she tried to prevail on her doctor to bring about an abortion From the start this mother saw the child as a “ monster ” who would grow up to revenge himself on her for her death wishes against him He cried almost continually throughout his infancy and she has described how she would hurl him into the bed screaming that he should never have been born The battle between mother and child had raged for practically the whole of his short life What we observe here is an event in pregnancy leading to a distortion in the mother's perception of her infant son It is understandable that she could be neither loving nor protective towards an avenging monster The improvement in the mother-child relationship and in the behaviour problem during the ten weeks' treatment was quite dramatic It was remarkable to contrast the original picture with the affectionate competent mother of a few weeks later

Yet another crucial epoch is the time of the delivery Of the greatest importance here is the reaction of the mother's near relations, especially of her own mother, and of her husband The fact that at this stage the father's role vis-à-vis the child is indirect does not mean that it is unimportant. In many eastern countries the birth of a daughter is still regarded as something of a tragedy, and husband and relations may make no secret of their disappointment Such crudity is not part of our western culture, but that is not to say that we have not our own pitfalls In some respects our highly organised obstetric routines may contribute to maternal anxiety

A mother may by chance be kept waiting a considerable time after delivery before having the infant brought to her There can hardly be a woman who, in these circumstances, does not rapidly become convinced that something is amiss with the child As she lies in anxious dread, self-accusation begins, and all the trivia of pregnancy assume immense proportions Both rational and irrational factors may play their part In recalling the events connected with a child's birth it is remarkable how often these mothers describe the midwife or the ward sister as a heartless tyrannical figure against whom the strongest feelings of fear and hate were harboured It is clear that in the great majority of instances there is no substance in these assertions, and that the conviction with which they are held is clear evidence of neurotic distortion The failure of doctors and nurses to understand this sort of mechanism can cause them to contribute unwittingly to these irrational attitudes, and this may have repercussions not only on the course of the labour but also on the mother's handling of the child

In certain circumstances the disturbed relationship is activated by the child

An infant may be born with a disfiguring congenital abnormality—e g , hare-lip It is very rare for the mother outwardly to reject such a child, but it is common for her to make this child the centre of her whole menage, sometimes to the neglect of her family, and, as it grows, to develop a pathologically overprotective attitude Personality disturbance associated with congenital abnormality is a subject ripe for investigation and may well be preventable in the first weeks or months of the child's life

Another, though much less obvious, example of the same kind of sequence of events is when the baby is extremely unresponsive This may happen before it is recognised that the child is mentally retarded, or deaf, or destined to show later the clinical picture of infantile autism (Kanner 1943), in which a striking component is disinterest in all human beings In instances such as these the mother is often observed later to be “ cold ” or “ detached ”, and this is invoked as a causal factor This may indeed contribute to a cumulative cycle of disharmony but need not have been the starting-point

Many women can locate precisely a moment at which they suddenly experience the feeling of being a mother—of having a child of their own This may be during pregnancy or at birth but is often delayed thereafter by hours or days Possibly, as in “ imprinting ” in animals (Tinbergen 1953), there are for mother and child critical points at which the relationship “ takes ” If so, it is understandable that separation of mother from child just after birth may have deleterious effects

Under ætiology we must include also the serious psychiatric disorders which may arise at this time—the puerperal psychoses In this event a healthy relationship with the child is impossible, and there is evidence that buried in every such psychosis lie powerful feelings of hatred towards the infant of which the mother is herself unaware In other mothers compulsive thoughts of damaging her child may appear in the early months or years of the child's life, but their roots go deep into the mother's own childhood, and other symptoms of the neurosis have probably preceded the pregnancy Conflicts about femininity which may have remained latent throughout her life may suddenly erupt when she is confronted with the tasks of motherhood, and express themselves as, for example, a profound disgust for breast-feeding The enthusiastic propagandist would do well in such instances to encourage bottle-feeding with scrupulous avoidance of disparagement

It will be seen, therefore, that we are at times confronted with psychotic or neurotic illness However, in many cases of disturbed mother-child relationship the mothers show little or no other evidence of emotional disorder These respond well and often with surprising rapidity to sympathetic interest combined with a reasonable understanding of the type of problem, without necessarily the technical sophistication of the specialist psychotherapist

Conclusion

Every now and again we encounter a mother who is not prepared to cooperate in the treatment or whose capacity for insight is extremely poor What is surprising is that this does not happen more often It is important that those directly concerned with the health of mothers and young children should become practised in the detection of these disorders, this is especially true of family doctors, pædiatricians, physicians, and health visitors in the maternity and child-welfare services Some will, by aptitude and inclination, wish to undertake the management of the cases themselves and should be encouraged to do so It must be emphasised, however, that success will not be forthcoming without acquiring the necessary technical competence This is probably best achieved by regular case conferences under the supervision of a child psychiatrist, who must also be available to take over the occasional case demanding expert intervention

Only by careful follow-up studies can the long-term effects of this form of treatment be assessed, but there are enough data to make us cautiously optimistic Already there can be no doubt that this work provides a field for interesting and potentially important research

ARTIFICIAL INSEMINATION

By a Practitioner

Amid the emotion, confused thinking, and uninformed opinion that surrounds the subject of artificial insemination by donors, it is perhaps legitimate to inquire why this procedure is ever contemplated and in how many families it is now used

Setting aside situations in which it would in no circumstances be considered by a doctor, what kinds of case remain as possibly suitable for AID and why?

The number of couples seeking this method of treatment is small and will always be so No couple would wish to have a child by artificial means if they could have one naturally The demand for AID is also limited by the fact that of the 8–9% of married couples who are subfertile, in only 1 in 10 is the husband irremediably sterile Fears that AID might become widespread are therefore groundless It is, and must remain, a small factor in the treatment of the barren marriage and a still smaller one in human affairs

It is difficult to estimate accurately the number of children already born as a result of AID One doctor who has practised it for about sixteen years has produced 69 babies by this means, and the total number of doctors using it at present in this country probably does not exceed ten

THE PARENTS

The classical cases are those of the married couple in which the husband has been proved to be irremediably sterile, or of the couple who, having suffered one or more rhesus tragedies, greatly desire to rear a family because they regard it as one of the most, if not the most, important objects of marriage

Such couples may choose AID rather than adoption because the husband prefers to bring up his wife's child rather than an adopted child propagated by two unknown people, and because the wife has the natural desire of every ordinary woman to produce and cherish an infant of her own

Such marriages are stable AID does not attract the frivolously minded couple who take a light view of marriage Husband and wife must have agreed together that AID is the right course for them Neither must have overridden the scruples of the other Neither must think it wrong that spermatozoa from a carefully chosen donor should be used to fertilise the ovum Such couples are, and must be, living a full married life together, which cannot always be said of cases where AIH is employed

The request for AID comes, more often than not, from the husband, who will either approach his general practitioner (not always with success) or make his own, often difficult, search for a doctor who will help him and his wife in this way

The doctor who performs AID must interview both husband and wife and be assured that the request comes from both He must further assure himself that the matter has been properly considered, and that the couple can offer to the child not only a reasonable standard of living but also the love and support that should be every child's heritage The doctor must be satisfied that the couple are mature and sensible—in a word, that they are childworthy

If the request comes through a general practitioner much of this preliminary "screening" will already have been done, for the couple will have been referred for AID only if the family doctor regards them as suitable

If the request comes from the couple, the screening and the final responsibility of deciding whether or not they should be helped in this way falls upon the doctor who is to perform AID

It is not always easy to refuse, but some couples have to be turned down—for example, where one or both are too old or medically unfit, where there is obvious instability and tension, or where one partner has persuaded the other unwillingly into the consulting-room In such cases it is often possible to find infertility factors in the wife, so that the doctor can advise against AID on that score as well as explaining the other difficulties

The responsibility, though a heavy and anxious one, is no more onerous than that assumed by those who arrange adoptions Indeed, in some ways, the chances of making mistakes are fewer, for an AID child will at least be reared by its own mother The handing out of a child, however engendered, to any couple who ask for one is a big responsibility, but experience suggests that it is more likely to go right with AID than with adoption

No doctor in his senses would try to persuade a couple to accept AID as a solution to their barrenness against their own judgment, religious beliefs, or ethical code Nor would he agree to use AID without the knowledge and willing consent of the husband

The manner in which a child is conceived is surely the parents' private concern provided that they deal fairly with their A.I.D. child (and experience shows that they do) and provided that, by having such a child, they do not defraud some other member of the family of a lawful inheritance without agreement. Such family agreements are made and will probably become more common. For example, the parents of a sterile son with a farm to hand on, which would have been sold if he had had no children, strongly advised him to allow his wife to receive A.I.D. These children have brought great happiness to the whole family, particularly to the grandparents.

There seems to be no point in informing the child, at any stage of its growth, that it is a "test-tube" baby. It is better to let it grow up accepting those who care for it as its parents.

THE OPERATION

Since A.I.D. is not a service that can be properly offered under the National Health Service, and since it involves complicated arrangements, the most suitable place for it to be done is the doctor's consulting-room. The timing of the procedure so as to give the best chance of success is difficult, especially for women who have to travel long distances to see the doctor and can perhaps manage only one visit a month. The correct day in the cycle can be decided only by studying the basal temperature charts, vaginal smears, the characteristics of the cervical mucus, the average length of the patient's menstrual cycles, and so forth.

It is always wise to explain to the couple that normal sexual intercourse should not be restricted during the period that artificial inseminations are being carried out.

The number of attempts needed to achieve pregnancy varies greatly from case to case, ranging from 1 to 4 times per cycle for from one to twenty cycles. The semen used should if possible be not more than three hours old, though success has been achieved with semen considerably older. It is best collected in polyethylene tubes and kept at cool room-temperature.

American workers[1] claim successful results with semen preserved by deep freezing, but their results have not been confirmed in this country.

THE DONORS

One of the most difficult and responsible tasks confronting the doctor who carries out A.I.D. is building up a list of donors. These should be personally known to him, but only in special and rare circumstances to the recipient. It is fundamental that the transaction remain entirely impersonal.

Donors must not only be fertile but also physically and mentally fit. They should be of various types and it is an advantage to have a long list from which to choose. The serological tests of donors must be negative and their blood-groups ascertained. They are used more or less in rotation, but some attempt is made to match the skills and aptitudes of the donor with that of the husband. A donor may be called upon from twice to twenty times a year.

Experience shows that, though couples may show interest in the physical and mental characteristics of the donor, once a child is conceived and born no further reference is made to him, unless another child is desired, when parents almost always ask for the same donor.

Donors should preferably be sought among married men with families of their own who donate with their wives' knowledge and consent, and without fee. The all too common gibes that donors must regard themselves as supermen or, alternatively, that they are irresponsible persons who donate for gain and without regard for the destiny of their seed are unfounded. Men of the right calibre will not donate unless they can trust the doctor responsible and can feel assured that their help is given only to childworthy couples.

THE CHILDREN

The bogy of intermarriage between half-brothers and half-sisters has been much exaggerated: the risk is certainly less than that of marriage between adopted or illegitimate sibs. The number of illegitimate births per annum is over 50,000 and of adoptions about 15,000, whereas an outside estimate of the annual number of A.I.D. births is 500. Though the donors may be drawn from a limited area, this is not true of the recipients, who come from far and wide.

A register of A.I.D. births, which would be open to inspection under proper safeguards by authorised persons, would put many minds at rest, but whether a satisfactory system could be devised can be decided only by those with expert knowledge of the legal and administrative intricacies of registration. It is, however, important that doctors practising A.I.D. should keep careful clinical records of every case, and, until enough information has been collected to answer more fully the questions in so many thoughtful minds, every effort should be made to keep in close touch with A.I.D. families.

In a series of more than 70 cases only 2 have been lost sight of, and nearly a third of them have returned for further A.I.D. In all there were 93 pregnancies in 70 women (69 live births, 4 stillbirths, 14 miscarriages, and 6 still in utero). The children born are satisfactory both physically and mentally. Though the children have a resemblance to the donor they tend to resemble more nearly their mothers and "fathers"—partly no doubt because they absorb their habits and facial expressions. The families have developed as a harmonious whole. So far no congenital defects have come to light. These A.I.D. families form only a small part of a much larger series of infertile couples investigated and treated, and since all cases are followed up there is no reason why A.I.D. families should feel conspicuous.

NATIONAL VARICOSE FOUNDATION

In July, 1956, the National Varicose Foundation was established and given four aims:

(1) To sponsor the building and maintenance of an independent varicose clinic, to be staffed by a team of specialists who could train and encourage others to take a deep interest in varicose veins and their treatment.

(2) To provide funds (*a*) to expand the present facilities at hospitals and clinics in Great Britain, and (*b*) to support clinical and scientific research at these and other centres.

(3) To explain to sufferers the underlying cause of their condition and so help them towards prevention, alleviation, and cure.

(4) To convince the authorities of the need for specialist-staffed varicose clinics and to help and advise, if requested, on the setting up of these within the framework of the National Health Service.

At a reception in London on May 15, Dr. STANLEY RIVLIN, chairman of the Foundation, spoke of the five million people in Great Britain with varicose veins and the half-million of them whose legs were ulcerated. The problem was gigantic, but it was the best of lost causes, for it was one that could be rescued. The present focus of the Foundation's aims was the erection of a specialist unit for outpatient and inpatient treatment and for research. A building fund has been set up from which it is hoped that a substantial new unit will emerge. Plans have already been prepared for this new London Varicose Clinic, which will contain an outpatient department, an inpatient department with 32 ward beds and 8 single rooms, a twin operating suite, a research department, and a lecture hall.

---

[1] Bunge, R. G., Keettel, W. C., Sherman, J. K. *Fertility and Sterility*, 1954, 5, 520.

The design of the outpatient department was based on experience gained in the present London Varicose Clinic at Battersea. Patients under treatment are dealt with together in one large room, where leg bandages are removed, and where patients sit talking until they are called in groups of 4 or 6 for treatment in a separate room. The inpatient department had been divided into 4 wards, each of 8 beds. The beds would normally be used for the treatment of varicose veins, for the treatment of ulcerated legs was ambulatory. Postoperative treatment of varicose veins included walking for five minutes every two hours, on the first and second postoperative day. Corridors had therefore been made wide to allow room for ambulatory inpatient traffic.

The twin operating suite consisted of a series of concrete "bubbles" intercommunicating to permit a "conveyor-belt" system of operating. A thorough operation on one leg by a single surgeon often took up to 1½ hours, and it was proposed to have a surgical team, the senior member to carry out only the vital part of the operation—the juxtafemoral ligation or juxta popliteal ligation. His first assistant then continued with the phlebectomy, and the second assistant did the sewing up and bandaging. It should thus be possible for one team to operate successfully and thoroughly on four cases a session, instead of the normal two.

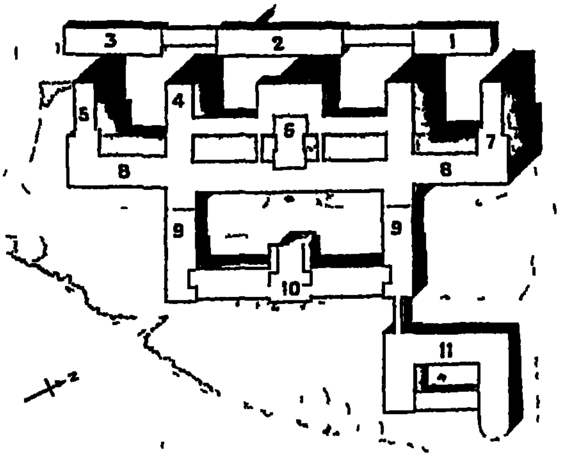
The unit was designed by Denis Clarke Hall, F.R.I.B.A., in association with Robin de Beaumont, A.R.I.B.A., honorary architect to the Foundation.

At the reception, Sir ARTHUR PORRITT wished the venture well, and guests were able to inspect a model of the proposed new clinic, which is estimated to need about £400,000 for its completion.

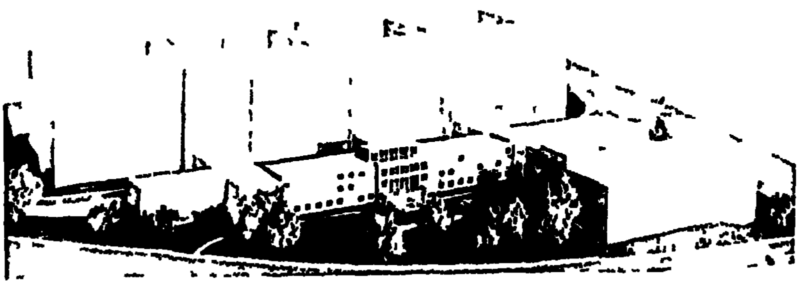
SHEFFIELD'S NEW TEACHING HOSPITAL

ON May 17, Queen Elizabeth, the Queen Mother, laid the foundation of the teaching hospital which is to be built on a site about a mile from the centre of Sheffield.

Plans for the new hospital were first discussed over thirty years ago. Shortly before the late war an appeal was launched to build it, and the trustees still hold a considerable sum of money collected at that time. An architectural competition was also held, which was won by the architects of the present building, Messrs Adams, Holden, and Pearson. But the war and post-war difficulties prevented building and it was not till 1953 that it proved possible to open the Charles Clifford Dental Hospital which was part of the original plan and which stands on an adjacent site.



1 Laundry
2 Boiler-house
3 Works department
4 Professorial unit
5 Staff-nurses' hostel
6 Main kitchen
7 R.M.O.s' hostel
8 Ward blocks
9 Polyclinic phase 2
10 Polyclinic phase 1
11 Medical sciences block



The new hospital when it is complete will be a comprehensive acute general hospital with 800 beds. It will of course be closely associated with Sheffield University, and it is ideally situated to form a hospital/university campus. It is also readily accessible to patients and visitors. It stands on some ten acres of land, and advantage has been taken of the sloping site to form interesting groupings of buildings and yet allow easy and convenient communication between them. At the highest level, at the back of the site, will be gathered the various service departments with a self-contained area for the delivery of goods. The inpatient block will be in the middle of the site with a through road to it. The outpatient and the laboratory block will be at the lower level and will also have its own road. The two blocks will be linked by corridors. The whole building is to be constructed in vertical blocks so that the planned extensions may be made horizontally.

When the outpatient department is completed it is hoped to go on as soon as may be with the next stage, which will provide 52 beds for inpatients, and then to continue the building programme steadily until the whole hospital is complete.

Occasional Survey

THE CONTRIBUTIONS OF SURGERY TO THE TREATMENT AND UNDERSTANDING OF PARKINSONISM

LESLIE OLIVER
M.B Lond , F.R.C S , F.A.C.S
NEUROSURGEON WEST LONDON HOSPITAL, ROYAL NORTHERN HOSPITAL, AND WEST END HOSPITAL FOR NEUROLOGY AND NEUROSURGERY, LONDON,
SENIOR NEUROSURGEON, THE NEUROSURGICAL CENTRE, OLDCHURCH HOSPITAL, ROMFORD

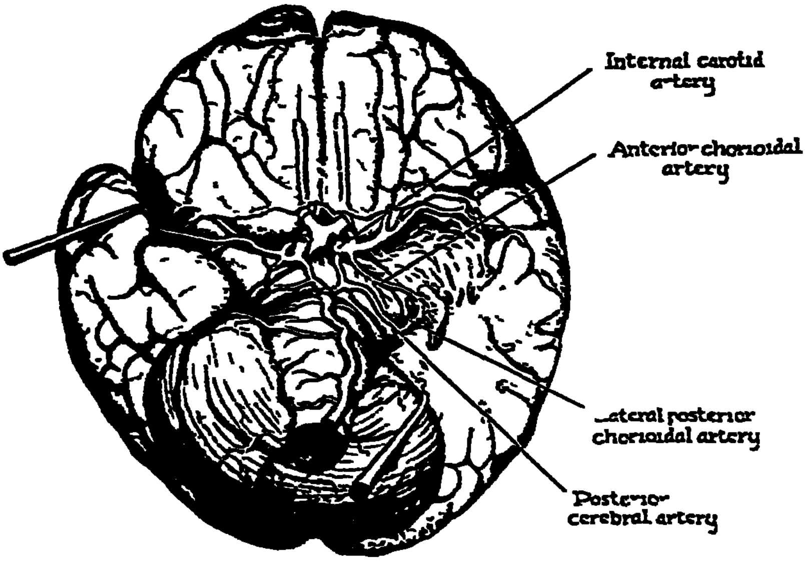
ALL methods of surgical attack in Parkinson's disease and postencephalitic parkinsonism aim at relief of symptoms No operation eradicates either of these diseases or arrests their evolution Tremor, often the most obvious manifestation, has claimed most attention from the neurosurgeons, but although it is the commonest early symptom and is present in variable amplitude in most patients with advanced parkinsonism it is far from being the chief presenting symptom when patients seek surgical treatment. Most patients then complain of disability, despite adequate muscular power there are slowness and poverty of movement. Some patients do, however, ask for relief from tremor, either because it embarrasses them or because it interferes with function

OPERATIONS

The operations will not be discussed in the order in which they were introduced but in an anatomical sequence which throws light on the route followed by the abnormal nervous impulses in the Parkinson syndrome

Operations directed at Globus Pallidus

While attempting partial section of one cerebral peduncle for contralateral tremor Cooper inadvertently damaged the anterior choroidal artery (fig 1) and was obliged to coagulate it. Pedunculotomy was then abandoned, but the patient was freed from tremor on the opposite side, although there was no hemiplegia and there were no other abnormal neurological signs which, according to the anatomical work of Abbie (1933), were to be expected



Internal carotid artery
Anterior choroidal artery
Lateral posterior choroidal artery
Posterior cerebral artery

Fig 1—Part of left temporal lobe has been removed to expose anterior choroidal artery By courtesy of Carpenter, Noback, and Moss (1954) and the Editor of *Archives of Neurology and Psychiatry*

As a result of this experience Cooper (1953) continued to coagulate the anterior choroidal artery for Parkinson's disease after angiography to demonstrate the artery and any variation of its origin It usually arises from the internal carotid artery just above the posterior communicating artery (fig 1) This operation relieved contralateral tremor in 55 patients

Although Abbie (1933) showed that many important structures could be stained by injecting dye into the anterior choroidal artery, Mettler et al (1954) showed that bilateral coagulation of the artery in the chimpanzee produced infarction of only a small part of each globus pallidus

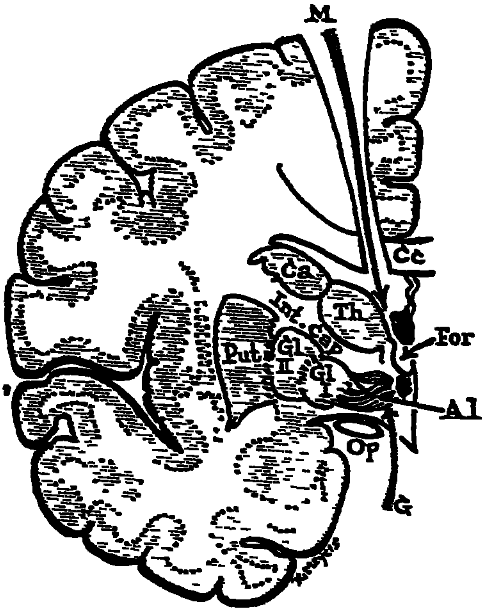


Fig 2—Russell Meyers diagram. A1, pallidofugal fibres (upper bundle is fasciculus lenticularis and lower bundle is ansa lenticularis) M, Meyers original transventricular approach to these fibres, G, Guiot's approach Ca, caudate nucleus, Th thalamus, Put, putamen Gl. I, medial segment of globus pallidus, and Gl. II, lateral segment of globus pallidus

Carpenter et al (1950) produced choreiform movements in monkeys by partially destroying the subthalamic nucleus and either reduced or eliminated these movements by partially destroying the contralateral globus pallidus These experiments were subsequently checked histologically

Coagulation of the anterior choroidal artery carries at least a 10% mortality and, despite the optimism of its originator, sometimes causes severe contralateral hemiplegia and other serious neurological complications This operation is therefore now rarely done having given place to less risky methods of destroying the globus pallidus—e g , injection of procaine in oil (Narabayashi and Okuma 1953), injection of alcohol (Cooper and Poloukhine 1955), implantation of radioactive isotopes (J B Campbell, personal communication), and mechanical means (Obrador 1957)

The most popular of these methods is injection of alcohol (chemopallidectomy) through a burr-hole, orientation being obtained by pneumoencephalography The mortality in 245 cases was 2·8%, and postoperative hemiplegia developed in

2% of patients, relief of tremor and rigidity was obtained in 70% (Cooper 1956)

Our knowledge of the role of the globus pallidus in the mechanism of parkinsonism is derived from the pioneering work of Meyers (1940, 1942), who tried several operations directed at the basal ganglia, but the most effective is section of the pallidofugal fibres—the ansa lenticularis and the fasciculus lenticularis (fig 2) Originally these fibres were cut through the lateral wall of the third ventricle approached through the frontal lobe and the anterior horn of the lateral ventricle Meyers (personal communication) reported the results of 22 such operations as follows

	No of patients
Much improved (tremor-free, some rigidity persisting, no neurological deficits due to surgery)	8
Improved (tremor and rigidity reduced but not abolished, or, if abolished, attended by some degree of post-operative dyspraxia, paresis, or spasticitv)	10
Unimproved	2
Operative mortality	2

Patients were followed up for at least 18 months and at most 13½ years

Meyers (personal communication) has abolished tremor and rigidity in 3 patients by subjecting the ansa lenticularis to irradiation by multibeam ultrasonic waves

Other workers claim good results from division of the pallidofugal fibres by other methods (Fénelon 1952, 1953, Guiot and Brion 1953, Spiegel and Wycis 1954)

Operations on Cortical Projection Areas

Horsley (1909) was the first to operate on the frontal cortex for involuntary movements He showed that removal of the precentral gyrus, area 4 of Brodmann, abolishes contralateral athetosis Bucy (1948, 1951) has also excised the precentral cortex for choreo-athetosis and for tremor The involuntary movements were eliminated at the expense of spastic paralysis of the affected limbs

Ward et al (1948) produced alternating tremor at rest in monkeys by electrocoagulation of parts of the reticular formation of the midbrain, and temporarily eliminated the tremor by excision of the motor and premotor cortex (Brodmann's areas 4 and 6)

Operations on Non-pyramidal Corticofugal Fibres

One of the operations tried by Meyers (1942) was section of the anterior limb of the internal capsule approached through the anterior horn of the lateral ventricle and exposed by removal of the head of the caudate nucleus After this operation there are transitory hemiparesis and persistent reduction of amplitude of the tremor

Pedunculotomy

Division of the lateral two-thirds of one cerebral peduncle for contralateral involuntary movements was first done by Walker (1949) In this operation both pyramidal and non-pyramidal fibres are divided There is diminution or elimination of tremor, but severe hemiplegia results

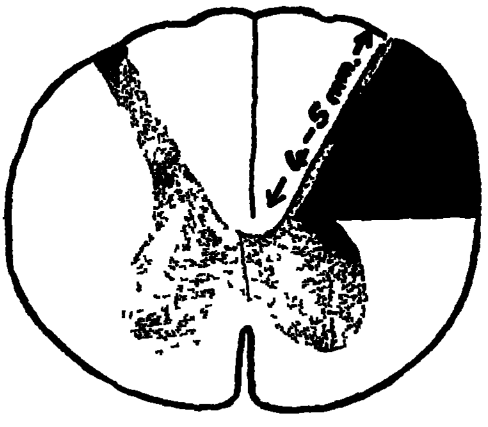

Fig 3—Putnam's (1940) chordotomy

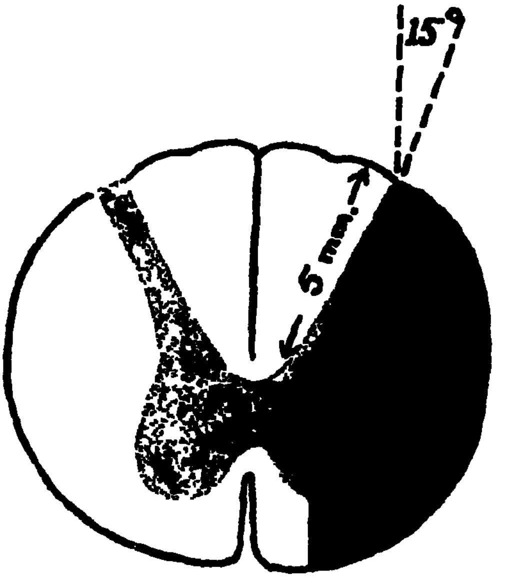

Fig 4—Complete section of lateral column

Operations on Spinal Tracts

One of the patients whose record appears in James Parkinson's (1817) monograph had a cerebral hæmorrhage and immediately lost the tremor on the hemiplegic side This fact, together with the observation that section of the pyramidal tract in monkeys causes little or no lasting disability, led Putnam (1940) to divide the crossed pyramidal tract unilaterally at the second cervical level for unilateral tremor (fig 3) There was reduction of tremor in 15 of 22 patients, and most of the patients completely recovered from the post-operative hemiplegia After this operation complete relief of tremor is not obtained, the tremor tends to return to its former amplitude (Oliver 1953) Unilateral tremor can, however, be entirely eliminated by complete section of the lateral column of the cervical part of the spinal cord (Oliver 1950) (fig 4)

Operations on any part of the pyramidal system should only be done on patients who have had hemiparkinsonism for at least five years without the slightest evidence of involvement of the other side The price of elimination of tremor by complete section of the lateral column is permanent hemiparesis and contralateral analgesia and thermanæsthesia of variable level but usually reaching the inner border of the arm Of 20 patients 18 were entirely relieved of tremor and 2 were only partially relieved Other workers have confirmed the results of this operation (Sjöqvist 1954, Gaches et al 1955)

DISCUSSION

Pallidectomy is the most promising advance in the treatment of parkinsonism and the most generally applicable operation It can be used both in unilateral and in bilateral parkinsonism, in the latter one side is done first and the other after an interval of at least three months This operation has a more lasting beneficial effect on rigidity and motor function than on tremor In long-standing unilateral parkinsonism in which tremor is the presenting symptom, either because it is embarrassing to the patient or because it is sufficiently severe to interfere with function, section of the lateral column is the more effective operation, but nevertheless unilateral pallidectomy should be tried first in such cases, because the patient may be satisfied with this, and damage to the pyramidal system is usually avoided.

The neuronal degeneration found in parkinsonism cannot be better defined than by quoting Greenfield and Bosanquet (1953)

> " examination has shown the lesions in the basal ganglia in our cases of idiopathic Parkinsonism to be slight by comparison with those in the brain-stem, and to differ in no respect from those found in many senile and presenile brains from cases with no symptoms of Parkinsonism. In post-encephalitic cases the lesions in the basal ganglia are often more definite, but in them also they are much slighter than those in the substantia nigra There is general agreement that in post-encephalitic Parkinsonism the *substantia nigra* is severely damaged and in some cases is reduced to a glial scar in which very few pigmented cells can be seen. In idiopathic paralysis agitans the lesions in the substantia nigra although usually less severe than in post-encephalitic cases, are always very evident when the various cell groups in this nucleus are compared with the normal "

In parkinsonism the affected neurons are in various stages of degeneration Brain-stem tumours and infarcts which completely blot out these cells do not produce parkinsonism, which therefore results from abnormally discharging neurons rather than from a release mechanism.

Electrolytic lesions of the reticular formation of the mid brain in monkeys cause tremor, and these lesions are composed of a zone of destruction surrounded by a zone of *degeneration*

It is suggested that the neurons of the substantia nigra —pars compacta or central portion (Mettler 1948)—send abnormal impulses to the globus pallidus in the strionigral tract, now recognised as an ascending pathway, although its name suggests that it is a descending tract (Keller and Harris 1941, Mettler 1943, 1944, 1945a and b, Ranson and Ranson 1942) The abnormal discharges leave the pallidum in the pallidofugal fibres (ansa lenticularis and fasciculus lenticularis), some of which are known to enter the ventrolateral nucleus of the thalamus (Rasmussen 1945) (It will be recalled that destruction of the globus pallidus or of the pallidofugal fibres diminishes or abolishes contralateral parkinsonism) The disordered impulses presumably then pass from the thalamus to the motor cortex and thence along the pyramidal or intimately related fibres, because excision of the motor cortex, pedunculotomy, or lateral-column section abolishes tremor The abnormal impulses are finally fed into the anterior-horn cells and thus interfere with muscular tone and function Sensory pathways seem to play but a passive role, because neither division of sensory nerve-roots of affected limbs (Pollock and Davis 1930) nor division of the posterior columns of the spinal cord in the cervical region (Putnam and Herz 1950) has any effect on parkinsonism

Conferences

NUTRITION AND HEALTH IN THE WEST INDIES

THE third annual meeting organised by the Standing Advisory Committee for Medical Research in the British Caribbean was held at the University College of the West Indies on April 12 and 13, under the chairmanship of Prof A C. FRAZER (Birmingham) and Sir GEORGE PICKERING (Oxford) Food in relation to health and disease was the theme.

Agriculture

Dr H. C. MILLER, director of the Jamaican Department of Agriculture. emphasised the need for increased agricultural production in underdeveloped countries Three-quarters of the land in Jamaica was mountainous, and there was available for production only [illegible] of an acre per head of the population In addition [illegible] of the 200,000 farms were under 10 acres Thus scientific farming or even the introduction of improved methods was time-consuming

Dr G GIGLIOLI (British Guiana) said that two-thirds of the workers on the sugar estates in British Guiana have been rehoused and provided with their own plot of land for vegetable production and poultry rearing Many families could produce more than enough for their own needs Malaria eradication had resulted in considerable improvement in nutrition.

Nutrition Surveys

A pilot nutrition survey of five low-income areas in Jamaica was reported by Dr K STANDARD, of the Government Nutrition Research Team The incidence and distribution of dental caries was shown to be related to the fluorine content of the drinking-water The children were thin and underweight according to British and American standards

Elementary-school children in British Guiana had been studied by Dr C C. NICHOLSON in 1950, 1951, 1952, and 1958 Since 1954 a snack meal consisting of skimmed milk, food-yeast-enriched biscuits, and fish-liver-oil capsules had been distributed to the schools In the 1958 survey the effect of this was apparent. There had been a remarkable improvement in health, but there were still some skin, eye, and mouth lesions that might indicate slight residual vitamin A and B deficiency

The value of milk supplements was also stressed by Dr L. HARNEY (St. Kitts), who pointed out that there had been a significant drop in infant mortality, compared with the " pre-milk era ", which did not appear to be due to other causes

The failure of vitamin B_{12} and aureomycin supplementation to influence the growth of protein-deficient Jamaican children was reported by Prof I F S MACKAY (U C W I)

Veno-occlusive Disease

Experimental production of veno-occlusive disease of the liver in calves was described by Prof G **Bras** (U C W I) and Dr D M **Berry** (Jamaica) *Crotalaria fulva* was the toxic plant The condition appeared to be closely similar histopathologically to that in man

Mayaro Virus

Dr W G **Downs** (Trinidad Regional Virus Laboratory) reported on the immunity to Mayaro virus found in the inhabitants of several West Indian territories It was confined to British Guiana and South-East Trinidad

Malnutrition

Malnutrition in infants was discussed by Dr B E R **Symonds** (Trinidad) In 69% of children who died between the ages of 1 month and 1 year, malnutrition was the sole or major contributory cause This was considered to be mainly due to ignorance or apathy on the part of the mother

Kwashiorkor

10 patients with kwashiorkor who had recovered were reviewed three and a half to five years later by Dr E H **Back** and Professor **Bras** All were well, 5 were below normal height and weight for their age, 4 had hepatic enlargement All the livers were histologically normal, including 1 that had shown fibrosis several years previously

Megaloblastic Anæmia

Nutritional megaloblastic anæmia in children about 1 year of age was reported by Dr J E **MacIver** and Dr E H **Back** (U C W I) This had been noted in 50 children over a two-year period—26% of all cases of malnutrition under the age of 2 years In these patients the hæmoglobin was less than in the usual cases of malnutrition, being 7 g per 100 ml or less All cases responded dramatically to the oral administration of folic acid 10 mg a day

Plasma-protein Levels

A paper by Dr B B G **Nehaul** (British Guiana) showed that in a group of East Indian patients the plasma-albumin level was lower and the plasma-globulin level higher than might be expected in a comparable series in Britain or America

Feeding Experiments

Mr C **Mendes** (M R C) showed that in weanling rats fed on a low-protein, high-carbohydrate diet growth was arrested and muscle-protein was considerably reduced—a situation similar to that observed in the protein depletion in the infant On refeeding there was a lag period before the synthesis of new tissue reached a maximum rate

Incidence of Cardiovascular Disorders

The low incidence of myocardial infarction in the Jamaican patient was pointed out by Dr J A **Tulloch** (U C W I)

The high incidence of aortic atherosclerosis in the Jamaican was demonstrated by Dr W B **Robertson** (U C W I) The findings were comparable to those observed in New Orleans On the other hand myocardial infarction appeared to be relatively uncommon, approximating more closely to the incidence in Guatemala

Placental Changes

Dr W B **Robertson** and Dr H G **Dixon** (U C W I) reported a combined clinical and pathological study of the maternal blood-vessels at the placental site in normotensive and hypertensive pregnancies in women undergoing cæsarean section Distinct changes in the vessels were noted in pre-eclampsia and in essential hypertension Intimal proliferation or swelling with considerable reduction in the lumen or sometimes complete occlusion of the lumen was found in the muscular and decidual vessels in the eclamptic or hypertensive woman

Adrenal Glands

The adrenal gland was shown to be notably smaller in the Jamaican patient than in the British subject by Dr G **Stirling** (U C W I) This change involved only the cortex and it was particularly distinct in children

In England Now

A Running Commentary by Peripatetic Correspondents

The importunate assimilators of reprints provide problems for impecuniary authors who do not work in university departments which usually pay both for reprints and for their postage Shall the author limit himself to the number of reprints given him by the editor and shall he send them, as some scientists do, only to those whom he knows to be working in the same field? If more reprints are to be purchased (and at a rising cost), how is he to forecast the popularity of his latest masterpiece? Will 200 meet the demands of these insatiable addicts? And if one's secretary says firmly, " No, 50 will do," how then to judge priorities when the postcards flow in like a river in spate?

If the principle of first-come first-served is accepted, then the few courteous Englishmen who wrote you a pleasantly phrased letter will soon be outnumbered by the senders of the stereotyped postcards (with a printed signature) from North America Then even the nice American from Baltimore, who gave you and your wife too many rocks on the rye last summer, and who scrawls " Love to Linda " (her name is Lucy) on his postcard, will be disappointed Rejected, too, will be that splendid solitary specimen of the anglophil Frenchman, the only physician in France who can understand what you have written Forgotten, also, will be that delightful South African —one of the few who replied in gratitude last year, having received an earlier and signal mark of your favour Omitted, too, would be those doctors behind the Iron Curtain, in Hungary and Rumania for example, towards whom one would be honoured to make so trivial a gesture of fraternity Rebuffed also the darling physician from Bucharest, who sent a postcard picturing the theatre at Cluj, and on the postage-stamp a portrait in sepia of Eminescu—a brilliant impression like an 18th-century mezzotint And, even more regrettable, to have left unsatisfied the redoubtable Latinist from East Berlin who wrote

> Honoratissimus Dr X
>
> Ista labor multum mea interest, quoniam similis investigationes perfero Oro, mittatis ad me supra dictum separatum atque alia separata similis generis
>
> *Manganese Deficiency in Cerebral Disorder*
>
> In publico propositum est Lancet I, Volume MCMLVIII, pagina DLXIII Multas gratias habete
>
> Vale

Or would you wish, Mr Editor, that I should enhance the circulation of *The Lancet* by refusing the requests of all these obsessional collectors, believing, as you and I do, that *The Lancet* is a journal to be bought and not merely to be read?

* * *

The parish church of Wirksworth, Derbyshire, is known for its beauty and even magnificence, and it is one of the oldest foundations in England, for a church certainly stood there in the 7th century There are many monuments in it to members of ancient local families—Lowe of Alderwasley, Blackwall of Blackwall, and Gell of Hopton—but there is also a simple mural tablet behind the pulpit which reads

IN MEMORY OF
WILLIAM WEBB, M D , F R C S , J P
DIED 27TH AUGUST, 1890,
Aged 59

I had often wondered how this highly qualified doctor came to have a memorial in this charming but tiny little country town So I looked up what the journals of the day had had to say about him, and he appears as indeed a man of parts He was in practice in Wirksworth for over twenty years and seems to have just about run the place

"Dr Webb was earnest and thorough in everything that he undertook, whether it was in politics in which he took an active interest or in the promotion of the sanitary improvement of Wirksworth which he sedulously advocated or in pleading the cause of the Cottage Hospital of which he was, from its foundation, the Medical Officer and active supporter "

One can imagine the enthusiasm with which this man of drive and initiative got the cottage hospital going at last somewhere in which the new Listerian surgery could be practised in a proper manner

But his health obliged Dr Webb to retire early from practice, and it is not perhaps too wide of the mark to hazard the guess that when he did so, his partner felt the need of a successor with surgical ability At any rate, in 1877 there came to Wirksworth none other than Frederick Treves True, he soon went back to London and to fame, whereas Webb's reputation remained local But I feel that this Wirksworth surgeon deserved his modest immortality in stone at least as much as the 16th-century grandees lying in their sculptured tombs in the chancel

Would you agree that the average English-male/American-female city-dweller has a tailored look, as if he/she had been poured into his/her suit? That he/she has every hair neat and slicked down as if he/she had just come from the barber's/hairdresser? And that he/she generally wears cuff-links/costume-jewellery and a set expression? While the average English-female/American-male city-dweller has a more casual look, as if she/he had bought her/his suit off the peg? That she/he has a more elemental hair-do, as if she/he had done it her/himself? And that she/he is inclined to wear rubber-soles/galoshes and a breezy expression?

* * *

The rugger type on the Holborn escalator nearly knocked me over in his rush But he found time to glare over his shoulder Now I can understand that he was in a hurry and had to push me out of his way, but what I can't understand is why he should bear me a grudge for it There is a lot of psychopathology to be explored on London's underground in the rush hour

* * *

A luxurious bank has been opened on the south side of Piccadilly Circus It is intended primarily for overseas visitors and was lately described in an evening newspaper as follows "The doors are of silver bronze bordered with red marble quarried from Oran, the source once used by the Romans for the Pantheon The close-carpeted interior has deep armchairs for customers"

What a contrast to the hospital scene 1958, where too often highly trained and qualified doctors, nurses, medical auxiliaries, are carrying out complex modern treatments in old buildings with out-of-date annexes, poor equipment, and overcrowded casualty and outpatient departments The general standard of hospital decoration and hygienic cleanliness is related, not to medical needs, but to a "pruned" hospital budget. How unfortunately the hospital, which is in continuous action 24 hours a day, compares with the bank How wonderful it would be if banks and other prosperous business concerns could be induced to sponsor and help the hospital capital development plans so that doctors will no longer be ashamed of the premises on which they work

* * *

"I had a pain in the mid watch," said the patient (from Portsmouth)

"Where's that?" asked the house-surgeon (from Pakistan)

"It's not where, it's when He means he felt it in the early hours—about pit-time," explained the staff-nurse (from the West Riding)

* * *

At Brightsea did the Councillors
A stately pleasure ground decree
Where through a pipe not far away
Town sewage bubbled on its way
Down to a sunlit sea

"A sewerage plant might there be placed,"
The M O H had shyly said
"What does the fellow contemplate?
The scheme would cost a five-bob rate,
Chap must be off his head!"

Letters to the Editor

THE ROYAL COMMISSION AND RESTORATION OF GENERAL PRACTICE

SIR,—Mr Wilfrid Adams, in his letter of May 10, makes some outstanding points on which I hope you will allow me to comment

"A successful outcome of the work of the Royal Commission depends on radical upgrading of conditions in general practice" At present what incentive is there to encourage good work or good conditions when the doctor who runs a first-class practice from first-class premises with all necessary ancillary help does not get paid one penny more than the doctor who practises from a lock-up surgery It is only heads that count The worst doctor gets the same money per head Surely now is a wonderful opportunity for the Royal Commission to make recommendations which will get this iniquitous system altered

May I make some suggestions?

(1) *An expense factor*—This would very broadly cover the G P's practice expenses as allowed for income-tax purposes and would directly encourage good work

(2) *Some form of merit award*—This would be given to those doctors who themselves do for their patients all the work for which they have been trained and are competent to do instead of dumping their "time-consuming cases" on the local hospital—a much more expensive procedure

(3) *Awards for higher degrees and diplomas*—It is true that some men find it much more difficult to pass exams than others, but would not membership of the College of General Practitioners show that the holder of this distinction was a man who had given an undertaking to keep himself up to date and to maintain the highest standards of medical practice and who was therefore worthy of recognition?

(4) *A locality allowance* (not to be confused with a mileage allowance)—This would be given to doctors who practise in difficult areas or where a large number of elderly people reside

(5) *Payment for experience*—At present in medical practice the experienced G P is paid exactly the same as his youngest colleague and has to work at top pressure till he retires or dies, whereas in most professions men earn their maximum rewards in late middle life with corresponding slackening of effort This could be achieved in many ways but would probably be most effective if it commenced about 45, rising slowly by yearly increments until age 60, when it would remain stationary until retirement Not only would a G P by this method be able to ease his work by a reduction in his list, without reduction of income, but it would also be a safeguard against any reduction in the ultimate amount of his pension

The all-important time factor

How is it possible, under the present system of remuneration, to give the average general practitioner the time to do his work properly, to give his patients a first-class service, and at the same time allow him opportunity for reading and reflection This point may well be causing thought amongst the members of the Royal Commission, indeed Sir Hugh Watson is reported to have remarked on it

To give a really good service in some 20-odd years of general practice I have found that for morning consultations fatigue begins to set in after about the 15th patient Visits vary according to travelling time, but 12 can be done comfortably, taking interest in each, before the work gets fatiguing This, followed by about 12 patients at night, gives a total of some 40 items of service per day, or a list of about 2500 patients At the present rate of remuneration it is argued that a doctor with a family cannot live and meet his expenses He is therefore forced to take more patients than he would otherwise like to balance his budget

Is it not possible that some of these suggestions could go a long way towards helping the G P to maintain a first-class service without being forced by financial necessity to take on more than he can efficiently manage?

Mr Adams has stressed the material factors just as important in my view are the psychological factors, the sense of bitter frustration, of being treated unfairly, of rankling injustice that is deep in the minds of so many doctors at the present day, which must be eradicated if we are to attract recruits of the right type into the profession

Worthing,
Sussex HAROLD LEESON

MORTALITY FROM CEREBRAL VASCULAR AND CORONARY DISEASE AMONG THE SOUTH AFRICAN BANTU

SIR,—In his stimulating letter of March 8 (p 528), Professor McMichael, referring to coronary-artery disease, states that "others would have us believe that the diet of the Bantu would save us, but the Pietermaritzburg pathologists, Laurie and Woods, think there is as much atheroma in the Bantu as in Barts" As two of those "others", we should be glad to comment on this statement

In the first place, the burden of Professor McMichael's letter relates primarily to *coronary-artery* disease and mortality In their comparison with Barts, Dr Laurie and Dr Woods[1] were referring to *cerebral vascular* disease in the South African Bantu While many believe that the diet of the Bantu is the factor of predominating influence in almost completely protecting them from dying from coronary-artery disease, no-one, to our knowledge, has speculated that their diet has an equal protecting effect against cerebral softening and hæmorrhage In this respect it is interesting to note that countries may differ considerably in the ratio of their mortality from these causes

(1) Mortalities may be high, approximately equally so—e g, England and Wales, Denmark and Sweden[2,3]

(2) Coronary-disease mortality may be low, but that from cerebral lesions high—e g, France, Italy[2,3]

(3) Coronary-disease mortality may be *very* low, yet cerebral disease may be a significant cause of death—e g, among the South African Bantu in Johannesburg, our information indicates that the former mortality is responsible for about 0 6% of deaths, and the latter, 3–4% of deaths[4,5]

(4) Mortality from both diseases may be virtually nil—e g, among Africans in Kampala, Uganda, in Dr Davies' series of 2994 necropsies, coronary-artery disease mortality was 0 03%, that from *cerebral vascular lesions, 0 3%*[6]

But to return to our local Bantu (for whom death certificates are required), it is evident that while mortality from coronary thrombosis presents no problem, this is not the case with cerebral vascular disease[7] It must be stressed, however, that mortality from cerebral vascular disease is still far less than among local white populations

Turning now from the mortality aspect to that of atheroma at this hospital, the proportion of deaths from cerebral softening and hæmorrhage is higher than in Pietermaritzburg, the impression gained, however, is that atherosclerosis of the cerebral vessels appears gross in a smaller proportion of relevant patients than is the case in the series of Laurie and Woods[1] Incidentally, these workers stress "the high prevalence of atherosclerosis and its cerebral complications in Bantu women—contrary to the findings in people of European descent" and quote Dr Lober[8] and the *British Medical Journal*[9] in support If this observation relates specifically to cerebral atherosclerosis and mortality, it is incorrect In the first place, there is a female preponderance of mortality from cerebral lesions in all the countries listed in the relevant World Health Organisation publication[3] More to the point, Dr Lober and the *British Medical Journal* both have in mind *coronary* sclerosis—the word *cerebral* does not even appear

It seems that the pathological lesions in the cerebral vessels of the South African Bantu are compatible with the mortality obtaining On the other hand, according to many observers, the extent of the lesions in the aorta and coronary vessels seem out of proportion to the very low mortality from coronary occlusion

In 1946, in a comprehensive study on Johannesburg Bantu, Becker[10] observed that "in spite of the fact that the coronary vessels are frequently in a diseased condition and the myocardium as frequently damaged, coronary thrombosis is an uncommon lesion" Furthermore, in his letter in your issue of May 10, Professor Becker reiterates that "on occasion" the Bantu develops atherosclerosis as severe as that seen in the local white population In the study of Higginson and Pepler[11] on 523 Johannesburg Bantu necropsies, about 4% showed "severe atherosclerosis of aorta, including ulceration and calcification, but in which atherosclerosis of coronary arteries does not significantly diminish the lumen" at the same time 2% of coronary arteries showed "marked atherosclerosis", mortality from coronary disease was 0 55% In the investigation of Laurie and Woods,[1] 16% of the 300 aortas examined showed "severe atherosclerosis with ulceration, calcification, and gross scarring", the state of the coronary vessels was not recorded, not one subject was mentioned as dying from coronary occlusion, not even in the larger series mentioned of 2000 consecutive necropsies Strangely, this finding evoked no comment

The main purpose of this letter is to stress this disparity in the Bantu between the occasionally severe atherosclerosis of aorta, although to a lesser extent of coronary vessels, and the low mortality from coronary occlusion

Even in Dr Davies' extensive postmortem studies in Uganda, where mortality from occlusion is virtually nonexistent, he stated "At Mulago a very high proportion of Africans coming to autopsy over the age of 50 show marked atheromatous lesions[6]" If thickening, ulceration, calcification, &c, arise largely from a succession of thrombotic episodes, it is not easy to understand why progression of these episodes leading to occlusion and death does not occur more frequently in these people Presumably, the "severe degree of coronary sclerosis" held by Lober[8] to be necessary, speaking generally, for symptoms and death, is not attained The usual argument trotted out over the Bantu not living long enough to die from coronary thrombosis is untenable, in Johannesburg there are 60,000 Bantu over 45 years, and 9000 over 65 years Using Professor Yudkin's phraseology,[12] *predisposing causes* in at least a proportion of the local Bantu are certainly present (atheroma, hypertension, stress, and smoking), against these range the pattern of their diet, infrequent obesity (except in women of 20 to 40), greater physical activity, and liver disease[7,13] (with combined ramifications in low serum-lipid components, high plasma-fibrinolysin activity,[13] &c), the *precipitating causes* obviously are virtually absent

Professor McMichael considers that "strong emotional devotion to corn-oil diets or anticoagulant pills will do no good to medicine" Prof Ancel Keys,[14] possibly more colourfully, has derisively inveighed against those who entertain the view that the coronary-heart problem may be solved without retreating from present high-fat diets merely "by taking a daily swig of linoleic acid and a few vitamin pills" We concur with these views Mere attainment and maintenance of a "favourable" blood-lipid picture per se need not reduce the chance of dying from coronary-artery disease, we believe that for that "favourable" blood-lipid picture to be effective, directly or indirectly, it may well have to lie within a particular dietary and metabolic context Although most writers regard it as premature to recommend significant changes in diet to ward off death from coronary occlusion, our belief is that the only certain known way to do this is by adoption of the pattern of diet (with all its concomitant metabolic ramifications) consumed by the Bantu and similar populations For this viewpoint there is much evidence, published and unpublished, which one of us (A R P W) hopes to present in the near future It would be naïve, however, not to recognise that the likelihood of any marked change occurring voluntarily in the diets of Western populations, no matter how frightening is the increasing mortality from coronary disease, is so remote as scarcely to merit serious discussion

NEW METHOD OF PHENOBARBITONE ADMINISTRATION

SIR,—I thank Dr O'Connor (May 3) for his reply

(1) I have accepted his facts and have said, giving reasons, that from them no conclusion can be drawn about the value of 'Spansule' phenobarbitone If its value was so great, why had other anti-convulsants to be simultaneously given, sometimes in increasing doses?

(2) The description of the rigid routine for administration of drugs, and the statement that the same nurses had attended the patients for a number of years, are new, though not very precise, data They do not amount to the required guarantee, especially with patients who were spiteful, cunning, paranoid, hostile, and suspicious

(3) There is a confusion here between improvement of personality, in which we all hope that psychotherapy has a great future, and relief from epilepsy, in which we all agree that it has not

(4) Added interest and stimulation on the one hand, and increased medication on the other, are not mutually exclusive alternatives I said, and meant, "may have helped"

(5) "Either wholly or in part"—there's the rub

(6) If 18 patients with, say, a hitherto invariably fatal disease were given a certain drug and all recovered, that number would be superfluously great for proof, but where everything is a matter of degree and careful assessment, 20 is nearly always the bare minimum I did not mention inert substances, the comparison should be with the same dosage of ordinary phenobarbitone, as suggested by Dr Pearson (April 19)

(7) "Striking" does not mean convincing There is no conflict here Kurtzke and Berlin's data were impressive except for two flaws the control series, having been earlier than the treated series, was studied retrospectively, and in the treated series both patients and doctors knew who was receiving a new treatment The parallel is close, and instructive to anyone who sees the same general difficulties in all therapeutic trials

Dr Levitt (May 10) seems to say that the paper is open to criticism but we ought not to criticise it I agree with him that the method may be of great value, would he agree with me that equally it may not? That is what I mean when I say that no conclusion can be drawn from the present data If I had thought that they should be ignored I should have ignored them instead of writing a letter about them

Perhaps we may now all agree to await the results of a controlled clinical trial

London, W 1
JOHN PENMAN

THE Y CHROMOSOME IN MAN

SIR,—Both the true hermaphrodite and the man with the uterus referred to in my letter of May 3 have elastic tissue surrounding the hyalinised seminiferous tubules of their testes This distinguishes them from Dr Ferguson-Smith's latest description of chromatin-positive microrchidism (May 3, p 928) It also alters the premises on which I based my argument on the function of the Y chromosome

JOHN GRAY

"THESE DYING DISEASES"

SIR,—The paper by Mr Ambrose King (March 29) concerning present-day problems of venereology was timely, especially in regard to gonorrhœa, in which there is the alarming situation of an increasing number of cases and an apparent lessening sensitivity of the gonococcus to penicillin

The number of new male cases of gonorrhœa seen in the clinics of England and Wales has increased by approximately 28% during the last two years, and the current figure for both sexes is virtually the same as it was as far back as 1949 At the same time doses of repository penicillins, which were once 95% effective, today produce far less satisfactory results Indeed, in recent series treated with single doses of 1 2 mega units of procaine penicillin with aluminium monostearate or of benzathine penicillin, failure-rates in the range of 18%–30% have been encountered

While similar experiences have not so far been widely reported in the U S A, the situation is certainly not confined to Britain At the recent World Health Organisation seminar in Tokyo it was evident that the declining powers of penicillin in gonorrhœa had been widely noted in the Far East Indeed, in a "sex store" in Yokohama, where I asked the proprietor what he used for gonorrhœa (drug-store treatment being legal in Japan), I was informed that for some time he had employed the tetracycline antibiotics, because penicillin was no longer effective

It is not known for certain whether the gonococcus is developing alternative metabolic processes or whether, as seems more likely, the apparent lessened sensitivity is arising from repeated selection of the more insensitive strains Further research is required In any event it seems that higher doses of shorter-acting penicillin preparations are required to provide higher peaks of penicillinæmia than are obtained with repository penicillins which the gonococcus now seems capable of overcoming This would mean the sacrifice of the so-called "epidemiological tail" provided with repository penicillins which act during the time that the consorts are being traced and which reduce the possibilities of reinfection of the original patient, and at the same time help to reduce the reservoir of syphilis "All-purpose" penicillins, by providing a higher initial level, and also a prolongation, at present give better results and might provide the answer, but, on the other hand, the existence of the " tail " itself may foster further relative resistance of the gonococcus

---

[14] Keys, A *ibid* 1956, i, 576

The treatment of gonorrhœa today presents a difficult problem and it was the consensus of opinion amongst participants at Tokyo that the deteriorating situation would tend to continue with increasing numbers of cases and further evidence of lessened sensitivity of the gonococcus to penicillin There is certainly no place for complacency

London, W 1 R R WILLCOX

AN EOSINOPHIL COUNTING CHAMBER

SIR,—Ever since the assessment of pituitary and adrenocortical function began to attract increasing attention, there has been much controversy about eosinophil counting New methods and techniques are proposed from time to time, but none seems to solve the problem It seemed to me that it would be better to concentrate on finding out the reasons for the shortcomings of the well-known acetone methods, which are far superior in their clarity, rather than use fluids whose viscosity and colour make it hard to identify the cells In spite of the meticulous care of analysts and statisticians, there is still something which confuses results when acetone diluents are used Fractions of the same blood sample treated by the Dunger, Rud, or other methods, give contradictory results under identical conditions, and simple experiments showed that even fractions of the same mixture, led simultaneously through pipettes to chambers of various capacity, gave results differing by from 30% to 50%, as the volume of the chambers was increased [1]

These findings suggested that the trouble lay in the way in which the cells sedimented in the chambers I found that during sedimentation the peripheral cells were driven towards the centre of the chamber, where cells accumulated, thus seriously affecting the accuracy of the count In all types of chambers, the periphery was depleted in this way when acetone was used On the other hand, this phenomenon was not noted in chambers filled with blood and other hæmatological fluids not containing acetone

It occurred to me that the cause of this migration (which is a phenomenon distinct from Poisson distribution) was the contact between air and acetone-containing fluid at the edges of the chamber, and I sought to overcome the difficulty by designing a chamber which would completely eliminate contact between drops and air during the counting

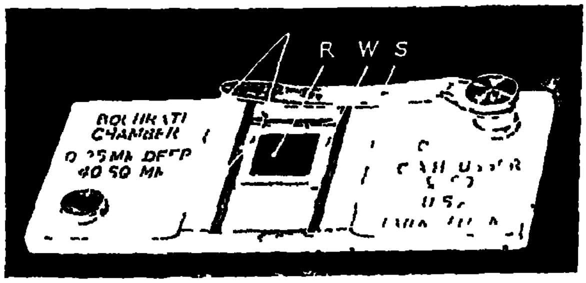

Fig 1—Photograph of counting chamber

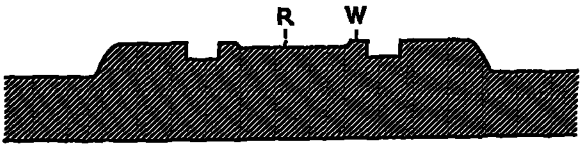

Fig 2—Longitudinal cross-section

In this chamber (figs 1 and 2) a wall (W) surrounds the ruled area (R) and prevents the drop of fluid in the chamber from coming in contact with air A support (S) holds the coverglass in contact with the drop Fig 3 shows how this chamber eliminates the migration which takes place in other types of chamber

A rectangular ruling (8×5 mm), in the Fuchs-Rosenthal pattern, gives large columns for easy reading It is unnecessary to load the chamber more than once for any particular count The ruling is divided into fourths by double median lines, thus permitting a count of half or quarter of the ruling in intense eosinophilia The big volume of the chamber (10 c mm) *means that the total count gives directly the number of* cells per c mm of blood, using a dilution of 1 in 10 The shallowness of the chamber (0 25 mm) overcomes the difficulty of sedimentation so common with deeper chambers The walls are inclined so that no foreign bodies can stay in it when the chamber is being cleaned Preparations can be left in the chamber almost indefinitely, and wet boxes are no longer needed The cells can be coloured in the chamber proper, without risk of desiccation or removal of cells

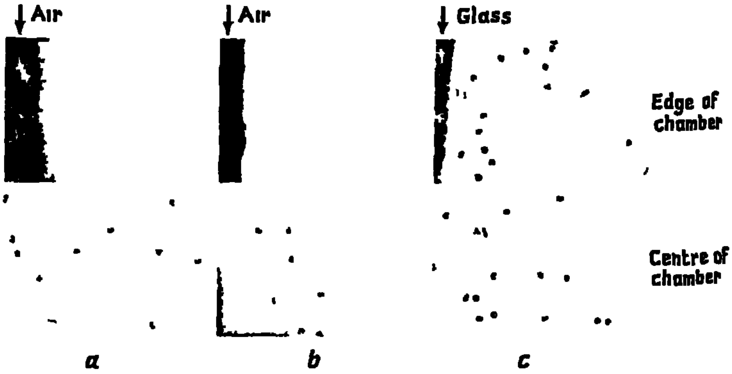

Fig 3—Photomicrographs illustrating migration in (a) Jessen chamber (0 4 mm depth) and (b) Fuchs-Rosenthal chamber (0 2 mm depth), and absence of migration in (c) Boghrati chamber (0 25 mm depth)

The distributors of the chamber are Evertex AB, 29, Stortorget, *Malmo, Sweden*

New York N BOGHRATI

RETROLENTAL FIBROPLASIA

SIR,—Your recent suggestion (April 26, p 893) to abandon the term " retrolental fibroplasia " and replace it by " oxygen-induced retinopathy of prematurity " may give rise to certain difficulties

For the past four " oxygen-conscious " years we have continued to examine the ocular fundi of all infants in the premature nursery of Babies Hospital at weekly intervals During this period there were 1060 admissions of infants whose birthweight was below 2000 g Five individuals developed retrolental fibroplasia, a substantially reduced incidence of this distressing condition as compared with four previous years Three of these infants had experienced only the briefest exposures (minutes) of supplementary oxygen and never in concentrations above 40% The ocular disease in these infants was in no way different from that observed previously in our nursery in many infants following prolonged exposure to high concentrations of oxygen

It is important to admit the possibility of the (rare) occurrence of retrolental fibroplasia as the result of exposure to only atmospheric concentration of oxygen (21%) An accurate history of " no supplemental oxygen " does not exclude the possibility of this disease The term " oxygen-induced retinopathy of prematurity " may be technically correct and

---

1 Boghrati, N *Brux méd* 1954, 34, 1945, 1999

does not exclude these rare examples that occur after exposure to 21% oxygen. I am concerned, however, that the use of this term will result in the erroneous exclusion of these cases in future reckonings because of misinterpretation of the limits of this category Our best interests will not be served if retrolental fibroplasia is spuriously eradicated by a glossological manœuvre.

Babies Hospital,
New York.

WILLIAM A SILVERMAN

A FIFTH MALARIA PARASITE OF MAN?

SIR,—Kindly permit me to make the following observations with regard to your annotation [1] on this subject.

Sinton and Mulligan [2] made a successful transmission of *Plasmodium knowlesi* to a monkey with *Anopheles annularis* and not *A maculipennis* as you stated.

The following report [3] regarding *P knowlesi* as a human infection, published in 1952, is also of special interest since it is based on an attempt at sporozoite-induced transmission, while the other reports, so far as we know, are based on trophozoite-induced transmissions

> "Differences in susceptibility of man to sporozoite- and trophozoite-induced infections of *P knowlesi* are also known Ray (personal communication in 1951) caused three batches of five specimens of *A annularis* harbouring sporozoites of *P knowlesi* to bite three human volunteers * After biting the human volunteers, each mosquito was dissected and the residual sporozoites were inoculated into three monkeys all of which took the infection Blood films of the volunteers were examined periodically and not one of them developed the infection in the course of ten months of observation About the same period, two white mice were inoculated each with two mosquito equivalents of *P knowlesi* sporozoites, and no infection could be detected in them during two months when their blood smears were examined daily Man, as already stated, is susceptible to blood-induced infections of *P knowlesi* but not to sporozoites White mice on the other hand are not susceptible either to sporozoite- or blood-induced infections of *P knowlesi* "

There is a mistake in reference 12 the name of one of the joint authors is Nair and not Mair.

DEATH OF A BOXER

SIR,—Having spent most of my active sporting life in the ring, I feel I should understand both the physiological stresses and the pathological lesions of the art of self-defence I was lucky in having a precisely developed postman's knockout punch to win six Irish university titles (1924–29), three British university titles (1927–30), and the heavyweight title of the R N V R. (1931)—all on knockouts None of my opponents ever suffered from any after-effects, and in all my close contact with boxing over thirty-five years I have never seen any permanent lesions caused by it. This great British game teaches a man to stand up and face both physical and moral stresses, which in my own eventful career has stood me well

I foster and admire the noble art, and in this town we have one of the finest boxing clubs in Kent.

Of course there are inherent dangers in all sport, as in life in general, but under proper medical supervision and the rules of the A.B.A and the B.B B C, character, the British bulldog breed, and fair play are fostered.

TREATMENT OF ASTHMA AND HAYFEVER BY HYPNOSIS

SIR,—This correspondence seems to provide data for an observation in what is probably the realm of social psychology or even anthropology three out of five of your correspondents have either not read the original paper with any attention, or have failed to understand it. Dr Moynahan (May 17) might not admit this sample of professional men as statistically significant, but we feel that such a finding of 60% among even a single group is unlikely to be without cause. As one possible interpretation we would point out the emotional affect still apparently engendered by the word " hypnotism "—much as it was by " mesmerism ' in the days of Lavoisier, recalled in Dr Moynahan's letter—and the suspicion or even distortion, of the facts, which such affect can produce in an observer

Our object in carrying out the experiment was quite clearly stated in the opening paragraph noting, with references, the value of hypnosis as a means of symptom relief (not cure) in allergic conditions, we then told how we " tested a patient's skin reactions to known allergens during the relief of associated allergic symptoms by hypnosis "—and we recorded our results. While endorsing Dr Moynahan's views on the education of present-day medical students in statistics and probability theory, we do not, however, believe that all experimental results are necessarily dependent on statistical analysis—although we admit, incidentally, it often seems that almost any result can be obtained (or refuted) by statistics

In our paper, therefore, we made no " therapeutic claims based on a solitary case " (Dr Moynahan), " good evidence of the value of hypnosis " (Dr Franklin, May 17) was not presented, since this was taken as read, and we never denied in any way that " individual case-histories can readily be matched from patients treated by either psychological or allergic methods." (Dr Pepys, May 10) Dr Pepys, in fact, was so busy submitting our report to " critical analysis " that he wrote of the " repeated vigorous skin testing (10 pricks were made into each site compared with the one prick commonly used for diagnosis) " From this he then proceeded to draw a whole series of conclusions The method used, however, was not the " prick test " at all, but the less traumatic and less desensitising technique of " multiple pressure ", with which the other was carefully compared at the outset Describing our actual tests we wrote " Multiple pressure through the drop was then exerted ten times, without scratching, with a sterile hypodermic needle "

Dr Pepys also suggested that " the inhibition by hypnotic suggestion of a single test on the left leg performed immediately on waking from a deep hypnotic trance, could be attributed to the well-known modification of peripheral circulation by hypnosis " This, of course, is possible, but if Dr Pepys consults table I of our paper, he will be able to count no less than 16 positive urticarial reactions recorded as a result of skin testing immediately " on waking from a deep hypnotic trance " On the one occasion, however, when direct suggestion was made that all skin reactions should be inhibited, there was no reaction on the left leg after testing—and we took this to be significant.

The problem of possible local hyposensitisation raised by Dr Pepys and subsequently by Dr Blair Macaulay (May 17) is of more interest and presents one of the inherent difficulties in designing experiments in this field as does the possible development of an anaphylactoid response when working with other materials

In general it will be found that different parts of the body give different degrees of allergic response to the same allergen when tested at the same time, but that the same part of the

2. Sinton, J A., Mulligan, H. W *Rec. Malar Surv India*, 1933, 3, 351
3 Prakash Satya Krishnaswami, A. K., Ramakrishnan, S P *Indian J Malar* 1952, 6, 179

* " One of the volunteers had never experienced any malarial infection at any time while the other two had malaria prior to 1943, 8 years previously, and underwent a radical cure.'

body tends to give approximately the same degree of reaction when tested over a period of time Tests on different parts of the body to avoid the possibility of local hyposensitisation would therefore be unsuitable for comparison and the results of the experiment meaningless Comparable tests were therefore carried out on the left forearm—though not exactly on the same spot each time—and the " prick test, the modified prick test, the scratch test, and the intradermal test " were all rejected in favour of multiple pressure, in the hope of minimising local hyposensitisation As it turned out this approach was reasonably successful According to the notes the patient in this case was seen on July 22, 1957, when her personal " hayfever season " was over and her full skin sensitivity was returned to her by direct suggestion under hypnosis Tested after waking on the left forearm, the responses were recorded on ' Sellotape ' in the usual way and stuck in the notes, though the actual areas have not been calculated by lead tracing and weighing They appear, however, to be approximately equal to those recorded during the third week of treatment, when the figures were B2, 139 sq mm , B3, 33 sq mm , and B8, 25 sq mm We apologise for not including these facts in our report

In this and further experiments on which we have worked, or are now engaged, hypnosis as such is not under investigation as a therapeutic agent, as Dr Moynahan and others seem to have assumed It is either being used incidentally for treatment in routine psychiatric practice (as in the case recorded), or we are employing it as a tool with which to manipulate psychosomatic and other phenomena in suitable volunteer hypnotic subjects Under investigation in both these cases are the physiological and serological changes influenced by hypnosis, and these occur particularly in association with conditions generally described as " allergies " von Pirquet[1] coined this term " allergy " as descriptive of " an acquired alteration in the capacity of living tissues to react " with specific reference to " old tuberculin " in sensitised subjects We have also investigated the psychic element involved in this, " the original allergy " Pace Dr Pepys (of the Tuberculosis Research Unit), we will shortly be publishing a paper which records the inhibition of a positive Mantoux reaction by means of suggestion under deep hypnosis thereby producing an individual Mantoux-positive in the left arm, and Mantoux-negative in the right At a subsequent session, this state of affairs was reversed, and the subject became Mantoux-positive in the right arm and negative in the left

We wish to thank your correspondents for their interest in our work

INTERMITTENT ALDOSTERONISM IN PERIODIC PARALYSIS

SIR,—We have read with much interest the article by Conn et al on periodic paralysis[2]

The principle of the salt-restricted diet, advocated in this study, has been applied to two patients with periodic paralysis We have not been able to confirm the hopeful results claimed by Conn et al

In one patient, who had severe paralytic attacks at least once a week, neither a diet containing 20 (or even 10) mEq of sodium daily, nor the combination with desalting procedures, prevented the recurrence of these spontaneous attacks

In his sister, who had a mild form of the disease, the administration of glucose and insulin, which provoked an attack on a normal salt intake, did not result in an attack when a salt restricted diet was given It seems as if the effect of the salt restricted diet depends on the severity of the disease

We have been able to confirm the retention of sodium (and of chloride) during the attacks This did not, however, precede clearly the retention of potassium and did not seem to be essential for the occurrence of an attack

EXTRACORPOREAL CIRCULATION

SIR,—I was much interested by your leader of May 17 I feel sure that many of us feel guilty in not having supported Professor Ian Aird and his team at the Postgraduate Medical School more wholeheartedly It is good to see the Postgraduate machine coming into its own

In Birmingham, we use the Lillehei-DeWall system and find its application to human patients admirable and it has entered the hospital routine In the last paragraph of your leader you mention that the main charge should fall henceforth on the National Health Service, and I do hope this advice will be heeded The establishment of a working heart-lung bypass apparatus in this hospital has been possible only because of a generous grant from the Endowment Research Fund, supported by one from the University of Birmingham

During the last year a team, always the same in personnel, has been working regularly and continuously in the laboratory Four medical members of the team and two whole-time technicians have mastered the techniques, and the same team is now operating in the hospital theatres Such a transition is expensive and as soon as it is taken over by the hospital authorities a financial allocation will be necessary for the continuance of the work, which is now long beyond the experimental stage

Birmingham

A L **d'Abreu**

AMERICAN REACTIONS TO THE STAPHYLOCOCCUS

SIR,—Your enlightened editorial of May 17 contains the seeds of progress, in the phrase " nobody has power to act " The general establishment of the post of hospital infection officer is merely another sop to the sleeping Cerberus, unless " he has power to act " Action is what is needed

An account of a successful eight-year effort to keep a well known maternity hospital free of infection was recently refused publication, probably because it contained too much boring detail If this detail is too boring to *read*, how much more boring it must be to *effect* in actual practice, unless one judges rather by results than by the deadly day-to-day routine

New lamps for old is still the cry, but Aladdin knows his literature, and clings to his ancient source of enlightenment The matrons still hopefully polish the lamp of Florence Nightingale but the genie eludes them Anyway, we have it on very good authority that Florence Nightingale did not believe in bacteriology[1]—or faeries either, probably

What is really needed is the atmosphere described so effectively by a very great and gracious Lady recently in Liverpool[2] she said, " Visitors are conscious of a pulse like a hammer and a vigour which nothing can daunt "

TOXÆMIA OF PREGNANCY

SIR,—Professor Theobald (May 10) asks me three questions First he says

> "Infants, non-pregnant women, and men die from renal cortical necrosis If toxæmia of pregnancy results from cortical ischæmia, why is eclampsia peculiar to the pregnant state?"

Briefly the answer to this is that in pregnant women (but not in infants, non-pregnant women, or men) cortical ischæmia is associated with retention of salt and water

Secondly, he asks why—if resistance to uterine stretch is the stimulus which provokes renal ischæmia—bilateral cortical necrosis practically never occurs in primigravidæ but is commonest in multigravidæ with accidental hæmorrhage The reason is that the extreme bursting force resulting from a concealed accidental hæmorrhage causes the extreme degree of renal shut-down that is characteristic of cortical necrosis

Thirdly, he asks how it is that patients with true eclampsia may secrete urine freely For this there may be several reasons

(1) Preceding attempts at treatment (e g, intravenous glucose) may have provoked an osmotic diuresis

(2) Drugs such as veratrone and apresoline may have reduced the vascular resistance

(3) Restriction of salt may have caused diuresis, as it does in the presence of œdema.

Diuresis is not, as might appear, incompatible with renal cortical ischæmia On the other hand, of course, a mounting oliguria is usual with impending eclampsia

London, W 1 JOHN SOPHIAN

VISITING PARENTS IN HOSPITAL

SIR,—Florence Nightingale in her *Notes on Nursing* (1859) wrote

> "There is no better society than babies and sick people for one another Of course you must manage this so that neither shall suffer from it, which is perfectly possible If you think the 'air of the sick room' bad for the baby, why it is bad for the invalid too and therefore, you will of course correct it for both It freshens up a sick person's whole mind to see 'the baby' And a very young child, if unspoiled, will generally adapt itself wonderfully to the ways of a sick person, if the time they spend together is not too long"

Professor Illingworth's plea (May 10) is timely The struggle to achieve daily visiting to children in hospital was hard but the results justified the endeavour

One of the next steps in the "humanisation" of our hospitals is the provision for ill parents to have their children visit them The same arguments used against daily visiting, namely the spread of infection and the subsequent emotional upset to the child, prove in practice to be quite unfounded

London, W 1 DAVID MORRIS

SIR,—I would support Professor Illingworth's plea for allowing children to visit their ill parents in adult wards

For the past two years we have allowed the children to visit all wards, other than obstetric or tuberculous, for half an hour on Saturday afternoons The ward sisters agree that, on balance, it is a good thing and much appreciated by their patients

There are difficulties It is not easy to limit the number of visitors at any bedside to two All the children have to come visiting, since it is often not possible to arrange for the care of any left at home

Very occasionally a child has been upset by seeing some hospital activity—e g a blood-transfusion in operation Again, a noisy baby can be disturbing to an ill patient Nevertheless, a good ward sister can deal with these minor troubles, and we should not wish to deprive the adult patients of these weekly family gatherings

Whittington Hospital,
St. Mary's Wing,
London, N 19 CECIL D COYLE

BONE-MARROW TRANSPLANTS

SIR,—The recent fundamental work on immunological tolerance and bone-marrow transplantation in animals was expected to lead to an outpouring of reports on its clinical application Only one major clinical study, however, has been published to our knowledge—that of Thomas et al [1] The reason for this reticence is probably the lack of convincing evidence of clinical success or failure

The recent preliminary communication of Dr Humble and Dr Newton (Jan 18), who have used the intra-aortic route of injection, has not contributed essentially to the clarification of this problem It is unlikely that the intra-arterial injection of a marrow suspension would be more successful than the intravenous route, which has been found to be effective in mice and to a limited extent in man [1] The avoidance of removal of cells by the lung and the closeness of the bone-marrow area to be repopulated by the graft do not appear to be factors of sufficient importance to warrant the risk of intra-arterial catheterisation In the past, successful direct injection of a bone-marrow suspension into a marrow cavity has never been reported Nevertheless, such preliminary reports as the one by Dr Humble and Dr Newton are apt to stimulate clinical interest in a procedure which will undoubtedly become increasingly important

Our experience with a patient in whom bone-marrow transplantation was attempted as a desperate measure may be of interest

A 36-year-old man with Hodgkin's disease of two years' duration had previously been treated with X-irradiation to the mediastinum and nitrogen mustard After ten months' remission, enlarged nodes developed in both axillæ and supraclavicular fossæ, associated with malaise, weight loss, and slight fever He was treated with a total dose of 15 mg of tretamine (T E M) over ten days, and two weeks after the last dose was found to have severe purpura caused by aplasia of the bone-marrow (Hb 7 g per 100 ml, white cells 500 per c mm, platelets 11,000 per c mm, bleeding-time>one hour) Bone-marrow aspiration from three sites revealed empty spicules with only histiocytic elements Three pints of fresh blood was transfused and prednisone was started at a dose of 100 mg daily, which was later gradually reduced He improved symptomatically, but a week later only the hæmoglobin value had risen (to 10 g per 100 ml), and there had been no change in the character of the bone-marrow, the agranulocytosis, and the thrombocytopenia

It was decided to attempt a bone-marrow transplant For the purpose of follow-up, the genotypical blood-group combination of the patient had to be determined, but because of the preceding transfusions this had to be done by examination of the parents, who fortunately were available The patient's genotype was O, M, CDe/cDe Bone-marrow samples were obtained under operating-room conditions from four suitable volunteers, the fat was removed and the bone particles filtered out with a Swinny filter syringe The pooled sample was suspended in Tullis solution and injected intravenously About 3×10^9 nucleated cells were injected Four donors were

---

[1] Thomas E D, Lochte H L, Jr, Wan Ching Lu, Ferrebee, J W. *New Engl J Med* 1957, 257, 491

N-positive and two donors E-positive (N and E erythrocytes, therefore, were suitable for survival studies in the recipient) Treatment with prednisone (40 mg daily) was continued Three days after the transplant, white cells were 4500 per c mm , with 75% polymorphs, and six days later, the platelet-count was 109,000 per c mm The reticulocytes started to increase (4 2%, red cells $4\ 5 \times 10^6$ per c mm)

Periodic bone-marrow examination revealed evidence of gradual recovery At present, seven months after the transplant and three months after the prednisone was stopped, hæmopoiesis appears to be normal, the nodes are no longer palpable, and the Hodgkin's disease appears to be in remission Weekly examination of the blood-group pattern, by the technique of differential agglutination,[2] with the N and E erythrocytes used as "markers", revealed a concentration of 50–56% N cells and 30–40% E cells, maintained for ninety days after the transplant and ninety-eight days after the transfusion Thereafter, the concentration declined, and a hundred and forty days later such cells could no longer be demonstrated

Unfortunately, because of the previous blood-transfusions, this cannot be considered absolute proof of a successful transplant Nevertheless, the possibility cannot be discarded that the graft was temporarily accepted and later rejected after the patient's bone-marrow started to recover, perhaps under the influence of prednisone Whatever the mechanism, the rapidity of recovery of this patient from tretamine-induced aplastic anæmia makes it likely that the injection of bone-marrow cells from four donors contributed to it

CATARACT A BIOCHEMICAL PROBLEM

SIR,—It was rightly pointed out in your annotation, Prospects in the Prevention of Blindness (March 15, p 577), that cataract is not a "senile" affection and that its nature is still unknown However, it was quite out of keeping with the theme being developed to end by placing in opposition the "one major surgical problem"—cataract—and all the other causes of blindness, classed as medical

One of the greatest hopes for the prevention of blindness lies in the elucidating of the biochemical changes which the lens undergoes during ageing and cataract formation, and it is to be hoped that before very long this important and widely prevalent condition will be removed altogether from the sphere of the surgeon

PAROXYSMAL NOCTURNAL HÆMOGLOBINURIA

SIR,—Dr Stratton and his colleagues (April 19) describe three cases of paroxysmal nocturnal hæmoglobinuria (P N H) in which severe hæmoglobinuria was stopped by infusion of clinical dextran

Some years ago, Crosby[3] stated that anticoagulants (especially heparin injections) lower the rate of hæmolysis "in vivo" But he repeatedly observed severe hæmolysis on cessation of heparin activity (referred to by him as "biphasic action") Thus he and many other authors warned against the use of heparin in P N H cases

During the last four years we have had the opportunity to treat 3 cases of P N H with heparin It was administered as an infusion, diluted in physiological saline in doses of 30,000–50,000 units per day Hæmolysis was immediately stopped It was even possible to carry out transfusions of whole blood during these infusions Furthermore, cessation of heparin activity was not followed by hæmolysis

Heparin infusion therapy was first published by us in 1955[4] Further details of the above treatment will be published in the German medical weekly *Klinische Wochenschrift*

TETANUS

SIR,—As your leader of May 10 suggests, the value of relaxants in the treatment of severe tetanus is still not accepted by all who treat this disease, but I am convinced that the number of reports of such patients recovering with relaxants will continue to grow I shall be publishing in due course details of two further cases recently treated successfully with succinyl choline and intermittent positive-pressure respiration (I P P R) These two patients had incubation periods of 8 and (apparently) 3 days, and periods of onset to major convulsions of 36 and 48 hours respectively

In the severe cases necessitating tracheotomy and relaxant drugs, respiratory paralysis must be produced and artificial respiration given with I P P R There is no advantage and considerable danger in trying to maintain a patient with sufficient relaxants to control the worst convulsions and not enough to depress respiration The care of this type of case throws a heavy burden on general hospital wards and I would make a plea for all such cases to be nursed in respiratory units when there is such a unit near at hand In a respiratory unit single cubicles are readily available and the management of I P P R is part of the normal routine

St Ann's General Hospital,
London, N 15

G DONALD W MCKENDRICK

IDENTITY DISCS FOR MEDICAL INFORMATION

SIR,—Although Dr Scott's generalisation (May 17, p 1069) that "considerable sections" of the civil population are actively immune to tetanus may sound, perhaps, overoptimistic, the fact remains that a not negligible number of immunised persons may be found amongst injured patients receiving attention in casualty departments As he so rightly states, there is much to be gained by ensuring that these people are given a booster dose of toxoid rather than an injection of A T S (Indeed, when there is incontrovertible proof of adequate immunisation in the recent past, even the booster may safely be omitted)

Unfortunately many of them (e g , young children, brought in from street accidents, unaccompanied by adult relatives) either cannot say anything about previous immunisation or give information which the casualty officer regards as of doubtful reliability In either case he tends to play for safety by administering A T S

The difficulty lies in ensuring that dependable evidence of previous immunisation shall always be available in times of emergency Record cards given to immunised persons, though important, do not appear to solve the problem, all too often the card is not at hand when most needed In a well-dragooned autocracy such information could doubtless be conveniently recorded by tattoo marks on the individuals concerned, but I imagine that few people in this country would take kindly to such a suggestion

One possible solution would be a return to the old wartime identity disc, worn on a bracelet or necklace A simple, but universally understood code could be devised whereby a great deal of information about a person's medical history could be packed into very small compass on the reverse side of an identity disc Items, other than the dates of toxoid injections, which might well be incorporated in the code are the individual's blood-group and warnings about such diseases as diabetes, epilepsy, hæmophilia, and allergy from which he might be known to suffer

---

[3] Crosby, W H *Blood*, 1953, 8, 769

[4] Lasch, H G , Linke, A , Sessner, H H *Acta hæmat* (Basel), 1955, 13, 366

To be effective the scheme would need to be organised on, at least, a national basis But better still would be an internationally agreed code-scheme With the increasing prevalence of international travel, the World Health Organisation might investigate the possibilities of some such scheme

SERUM-TRANSAMINASE ACTIVITY

SIR,—In a description[1] of a method for the estimation of serum-glutamic-oxalacetic-transaminase (GO-T) and glutamic-pyruvic-transaminase (GP-T), a provisional normal range was given for the units defined therein The serum-transaminase activity of 75 "normal" adults of both sexes has now been estimated by this method, and the statistical analysis of these results is shown in table I

TABLE I—SERUM-TRANSAMINASE ACTIVITY (UNITS)

—	—	Range	Arithmetic mean	Standard deviation	Statistical normal range (m±20)
GO-T	Men	35–107	70·43	±18·32	34–107
	Women	28–113	67·04	±16·54	34–98
	Total	28–113	68·73	±17·47	34–104
GP-T	Men	27–105	53·95	±20·25	13–95
	Women	17–92	47·95	±17·61	12–83
	Total	17–105	50·67	±19·21	12–89
$\frac{\text{GP-T}}{\text{GO-T}}$	Men	0·32–1·22	0·77	±0·19	0·39–1·15
	Women	0·24–1·15	0·72	± 0·24	0·24–1·20
	Total	0·24–1·22	0·75	± 0·22	0·31–1·19

No variation with age was noted The distribution curve, as found in other enzyme assays,[2] was slightly skewed to the right giving a "lognormal" type of curve[3] With such an assymmetric distribution it is impossible to define a normal range in terms of mean and standard deviation, and table II gives lower and upper 1% levels and lower and upper 10% levels[2 4] 80% of the distribution is enclosed by the latter figures and 98% of the distribution by the former, results falling outside the 1% levels may be regarded as abnormal

TABLE II—RANGE OF NORMAL SERUM-TRANSAMINASE ACTIVITY (UNITS)

—	Lower 1%	Lower 10%	Upper 10%	Upper 1%
GO-T	35	42	95	107
GP-T	22	28	78	92
$\frac{\text{GP-T}}{\text{GO-T}}$	0·28	0·42	1·00	1·12

Using the unit proposed[1] (namely, that which will transform 1μ mole of α-aminoacid to 1μ mole of α-ketoacid in one hour at 37 C under the conditions described), and expressing activity per 100 ml of serum as in tables I and II, we have assayed both transaminases in various pathological conditions and determined their ratio $\frac{(\text{GP-T})}{(\text{GO-T})}$ The ratio has been found useful, being within normal limits in cases of uncomplicated myocardial infarction and usually elevated in hepatic dysfunction The value of the determination in pulmonary tuberculosis, where levels are raised, is being studied, and its use is being investigated in the differential diagnosis of rheumatoid arthritis and rheumatic fever, where low and raised levels respectively have been found

Further details of these investigations will be published later

UNILATERAL NEPHRECTOMY PREOPERATIVE TREATMENT OF HYPERTENSION

SIR,—Removal of a phæochromocytoma and unilateral nephrectomy are now standard operations for the relief of severe hypertension in appropriate cases The patient's life may, however, be jeopardised after otherwise successful surgery by the damaging effect on the kidneys, or remaining kidney, of the postoperative drop of blood-pressure This results in oliguria and may proceed to irreversible uræmia It should be stressed that the postoperative blood-pressure level at which this complication may occur is higher in a severely hypertensive than in a previously normotensive patient

It would, therefore, seem rational in these cases with sustained preoperative hypertension to precede operation by 3–4 weeks of medical treatment with ganglion-blocking agents, resulting in a gradual drop of blood-pressure During this period the necessary vascular adaptations may slowly take place in the kidneys and brain, with a much smaller risk of infarcting these organs This is never far removed when the blood-pressure is suddenly lowered drastically from any cause in elderly or severely hypertensive subjects

H J GOLDSMITH

FRACTURES OF THE PARIETAL BONE IN CHILDREN

SIR,—Mr Maurice Ellis[1] is incorrect in thinking that superficial collections of cerebrospinal fluid associated with linear fractures of the parietal region have not previously been reported The condition is clearly described, and indeed illustrated, in the first edition of Rowbotham's *Acute Injuries of the Head* Mr Rowbotham calls them traumatic meningoceles—a clear and descriptive term—and stresses their common occurrence in children owing to the relatively adherent dura in young people

I have encountered a number of cases, but the outcome has not always been as happy as in those described by Mr Ellis

In 2 the swelling has persisted and the underlying bone has been gradually absorbed so that a linear crack in the skull vault has become converted, over a period of six months or so, into an irregular oval defect in the skull Rowbotham also describes and illustrates this event, referring to it as malacia of the underlying bone and noting that at a later stage brain may also herniate through the skull defect It is because of this possibility that I believe that early dural repair is advisable A small bone flap is turned down over the affected area and the dural defect is repaired either by simple suture or fascial graft The torn dura is usually found firmly adherent to the bone and trapped in the fracture line

In a further instance a similar skull defect appeared at the site of a linear fracture although swelling beneath the scalp had subsided within a few days of injury

I feel, therefore, that dural repair is indicated in all these cases or, in default of such repair, careful radiological follow-up for at least a year

Department of Neurosurgery,
University of Birmingham
BRODIE HUGHES

SIR,—Mr Ellis describes a condition which is well known to neurosurgeons and those whose business it is to care for patients suffering from injury to the head It is commonly termed traumatic meningocele [1]

While it is usually found in children, it is also seen in adults There is no reason why it should be confined to the parietal region, and it does in fact occur in other positions over the skull I have also seen it occur over a fractured sacrum

Swansea
NORMAN WHALLEY

PARADOXICAL ELECTROCARDIOGRAM IN CORONARY EXERCISE TEST

SIR,—Dr Geoffrey Bourne's report [2] on the change of an ischæmic T wave to a normal pattern after exercise prompts me to report two experiences

Several years ago I was shown a series of electrocardiograms of a patient with raised S–T segments, typical of recent infarction, the tracing became normal after an inhalation of 90% nitrogen Perhaps I should add that I understand that the patient suffered no ill effects from this myocardial assault

My own experience concerns a 40-year-old lady referred to me by Dr James Power A rather routine cardiogram done in January, 1957, revealed flattened or inverted T waves in all leads, there was no clinical evidence of myxœdema, Addison's disease, coronary disease, or old pericarditis, and the patient was thought to be suffering from mild neurasthenia A further tracing done in August showed a like record, and an exercise-tolerance test demonstrated a normal electrocardiogram with upright T waves in all leads (All records were taken in a semi-recumbent position) I am at a loss to account for the cardiographic changes in my patient

MORGAN MCELLIGOTT

LEVEL AND STABILITY OF BLOOD-GLUTATHIONE AFTER SPLENECTOMY

SIR,—The presence of Heinz bodies in erythrocytes of about 55% of patients after splenectomy was reported in 1955 by Selwyn,[3] who also put forward evidence that phenacetin could be responsible for their appearance in some cases Recent investigations of favism and hæmolytic anæmias induced by several drugs (primaquine, sulphonamides, *p*-aminosalicylic acid, naphthalene) proved that these conditions, in which Heinz bodies also appear, arise in people with an intrinsic hereditary abnormality of erythrocytes

This abnormality is manifested by defective activity of glucose-6-phosphate dehydrogenase, and low unstable blood-glutathione (G S H), and defective incorporation of glycine into the G S H [4–9]

Heinz bodies have also been reported in hæmolytic anæmia of the newborn after administration of vitamin-K analogues [10] Zinkham and Childs [7] found a transient non-hereditary blood-glutathione instability in all the newborns so far studied [7] The latter is not connected with deficient activity of glucose-6-phosphate dehydrogenase, and may be corrected in vitro by addition of glucose or inosin to the blood [9]

In view of these recent developments, we thought it interesting to investigate whether the appearance of Heinz bodies after splenectomy was also connected with some glutathione abnormality

Another reason for interest in the blood-glutathione after splenectomy was the possibility that it might be influenced by a change in the erythrocyte population following the removal of the spleen (e g , increased number of target cells and total erythrocyte-count in thalassæmia after splenectomy [11])

We examined the G S H level and its stability in 16 patients, six months to four years after splenectomy, by the method of Beutler [4] The patients were Ashkenasian Jews originating from Eastern or Central Europe (9 cases), and Sephardic Jews from Iraq (4), Persia (1), and Yemen (2)

In 14 cases the glutathione was stable and its concentration within normal limits The mean G S H content was 68±12 4 mg per 100 ml erythrocytes (in 300 control cases mean G S H was 70±13 4 mg per ml 100) In the erythrocytes of 2 of these patients (women of East European origin) occasional Heinz bodies were found

In 2 patients (men of Iraqi and Persian origin) the G S H was low (27 mg and 40 mg per 100 ml erythrocytes) and unstable Its content fell to 6 and 3 mg per 100 ml as a result of incubation with acetyl phenylhydrazine Few Heinz bodies were found in the blood of 1 of these patients, while in the 2nd they were seen in about 1% of erythrocytes

In view of these findings we think that splenectomy does not cause blood-glutathione abnormality This conclusion is probably not contradicted by the finding of the G S H instability in the last 2 patients, because we have previously found this defect of erythrocytes in about 20% of Jews originating from Iraq or Persia [9]

Medicine and the Law

A Conviction for Unlawful Killing

AT the Central Criminal Court on May 19,[12] Dr Louis Aimee Newton was found guilty of unlawfully using an instrument with intent to procure the miscarriage of a 35-year-old Australian nurse on Oct 11, 1957, and of unlawfully killing her by using an instrument Mr Justice Ashworth passed sentence of two years' imprisonment on the first conviction and three years on the second Dr Newton was found not guilty of manslaughter on the ground of professional negligence

According to prosecuting counsel, the nurse had consulted a psychiatrist, Dr Ellis Stungo, who had advised abortion because of her state of mind Dr Stungo communicated with Dr Newton, who carried out the operation for a fee of £75 After the operation he saw her to a taxi which took her back to her hotel The patient died in hospital two weeks later, and death was attributed to renal failure following abortion

Dr Stungo was charged with counselling and procuring Dr Newton to unlawfully use an instrument, but at the close of the evidence for the prosecution [13] defending counsel successfully pleaded that there was no case to answer and Dr Stungo was discharged

In evidence, Dr Newton said that he visited the patient at her hotel after the operation and he found her pulse and temperature normal, though she said she felt sick He thought she was making a slow recovery and in his judgment she was not sufficiently ill to get disturbed about He admitted that he was wrong in his diagnosis in the first place, but he denied that he was grossly or criminally negligent in his treatment.

[13] *ibid* May 16

Dr R. A Brews said [14] he was familiar with the preparation used to procure the abortion, but he would not himself use it for this purpose The proper place for an operation of this kind was in hospital or in a properly equipped nursing-home. Prof J C McClure Browne said [15] that, having heard Dr Newton describe the operation, he thought his technique perfectly reasonable It was very difficult in the early stages, in this particular situation, to recognise anuria and he could understand somebody failing to recognise it.

Counsel for the prosecution suggested [15] that the evidence disclosed an illegal operation, and when it went wrong Dr Newton did everything he possibly could to avoid discovery In doing that he disregarded the skill he should have displayed in exercising his professional services

Summing up, Mr Justice Ashworth called this an unusual and important case. It was important from the Crown's viewpoint because if the jury took the view that this was a case of criminal abortion they might well agree that criminal abortion was more sinister and more difficult to detect when it took place in the high places of Harley Street than in the drab surroundings usually associated with the crime The emphasis was on the word "unlawful" the use of an instrument was unlawful unless it was used in good faith to preserve the life or health of the woman, and the Crown had to establish that it was not used in good faith.

Passing sentence, the Judge referred to the fact that Dr Newton's name was removed from the Medical Register from 1942 to 1947, after he had appeared before the General Medical Council for offences relating to false certification.

Obituary

CHARLES SYDNEY ATKIN

B.A, M B Cantab

Dr Atkin, who died at his home on May 9, came of a long line of Sheffield doctors His father, the late Dr Charles Atkin, F.R.C.S, his grandfather, and his great-grandfather all practised in Sheffield

Born in 1889, he was educated at Marlborough, Caius College, Cambridge, and St Bartholomew's Hospital, qualifying in 1913 After settling in Sheffield he was for some years a consulting physician at the Children's Hospital there, and during the war of 1914–18 served as captain in the R A M.C with the British Expeditionary Force

He was a fine athlete, a member of the Cambridge University hockey team, 1909–10 He played hockey for England against Wales, Scotland, and France in 1913, took part in the Olympic Games in 1920, and played against Ireland in 1921 He was also a good tennis player, representing the Hallamshire Tennis Club for several years Later he became a keen shot and fisherman.

W R S and E G M write

Dr Atkin's professional outlook reflected his family tradition of unstinted service, his university and hospital background, his knowledge of men in sport and war, and a long sympathetic experience in practice

He gave his patients, with all his medical skill, the kindliest understanding and his untiring devotion No patient ever found him unresponsive to a call for medical help or for moral support and encouragement—but his sympathies not seldom cost him more than the recipients knew

On medical boards—as member and later as chairman—his experience and insight, with his charitable tolerance, were a support to his contemporaries and an education to his juniors

Dr Atkin is survived by his widow, a daughter, and two sons, one of whom is a doctor, now the fifth generation of the family to practise in Sheffield

Public Health

Smallpox

A MAN and his wife have been admitted to New Ferry Smallpox Hospital in Cheshire There is known to have been contact between these patients and the original cases of smallpox in the district last month [1] The man is reported [2] to be seriously ill, but the wife's illness is described as mild. The man was admitted for a few hours to the isolation block of Clatterbridge Hospital before being transferred to New Ferry Hospital after the diagnosis had been confirmed. Contacts are being interviewed and offered vaccination

Eire in 1957

IN Eire last year [3] the birth-rate was 21 2 per 1000 population, which was 0 2 above the rate for 1956 The death-rate—11 9 per 1000 population—was also 0 2 above the rate in the preceding year The maternal-mortality rate was 1 31 per 1000 births registered, compared with 0 82 in 1956 The infant-mortality rate was 33 per 1000 births registered, and the neonatal mortality rate 22—compared with 36 and 23 respectively in 1956 The death-rate from tuberculosis (all forms) was 24 per 100,000

Parliament

QUESTION TIME

Temporary Posts Overseas

Mr JOHN TILNEY asked the Minister whether, in order to help ease the medical requirements of Commonwealth Territories and to expand the knowledge of tropical medicine and problems among members of the National Health Service, he would recommend the proleptic appointments of consultants so that they can do a tour of duty overseas before taking up such appointments —Mr WALKER-SMITH replied I am advised that the National Health Service Acts do not permit me to do so and I am not convinced that what is proposed would achieve the object in mind I am, however, considering various representations which have been made to me on the subject

Artificial Limbs and Appliances

Mr C SIMMONS asked the Minister whether he would indicate the steps now being taken to develop the work of the department of research and experiment to secure improvements in the design, performance and fitting of artificial limbs, and the extent of any cooperation which existed to secure precise information about new artificial limbs and appliances available in other countries —Mr RICHARD THOMPSON, parliamentary secretary to the Ministry, replied Since last year, the work of the research department at Roehampton has been under the regular supervision of a small executive committee of the Standing Advisory Committee on Artificial Limbs On the recommendation of these committees, a special plastics laboratory is about to be established The research staff keep in close touch with colleagues in other countries by correspondence, exchange of literature and samples, and by visits Two members of the staff are at present visiting research establishments in the United States

Poliomyelitis in the Vaccinated

Poliomyelitis developed in 1957 in 8 (5 paralytic), 5 (2 paralytic), and 6 (3 paralytic) children in the first, second, and third months respectively after two injections of poliomyelitis vaccine In one case, which occurred in the first month, the child had paralysis affecting the inoculated limb

Protective Helmets for Motor Cyclists

According to estimates made by the Road Research Laboratory, over 500,000 motor-cyclists (47%) now use protective helmets

Notes and News

THE ROYAL SOCIETY

For almost a century, its conversaziones have been a notable feature of the annual programme of the Royal Society But it seems unlikely that, in all this time, the exhibits have ever presented a more striking series of contrasts than they did this year Among the demonstrations to be seen at Burlington House on May 15, one related to the tracking of satellites (including some recordings made that day of the newly launched Russian giant), and another to the study of dinosaurs' brains The results of natural selection on certain species of snails could be contemplated during a programme that also included a film on the problems of transonic flight And, though perhaps the most beautiful of all the exhibits was that showing the mode of formation of ice crystals at sub-zero temperatures, certainly the largest was a working model of Sceptre, the reactor in which temperatures of some four million degrees have been generated

The equipment for polar research, developed by workers of the National Institute for Medical Research, struck a topical note It included an improved type of sledging ration, a method of carrying liquid propane in lightweight containers for use as a fuel, and a fabric knitted out of very flexible insulated wire Underclothes made of this wire will, appropriately connected, function as resistance thermometers, and can then be used to measure skin-temperature But it is likely that the fabric will find its most important application in the construction of electrically heated clothing, for it can be worn next to the skin and will there produce a maximum heating effect for a minimum energy input

There were two other items of great medical interest Sir George Pickering and his colleagues at Oxford showed how they had been investigating the distribution of the pressor substance, renin, in the kidney The problem of separating the nephron into its glomerular and tubular elements had been overcome by invoking magnetic forces in an ingenious way The intact kidney was perfused with a suspension of magnetic iron oxide, the particles of which are filtered off by the glomeruli The kidney was then ground up in Locke's solution, and this suspension was passed in a tube through the field of a powerful electro-magnet The glomeruli were arrested by virtue of the oxide particles they contained, while the remainder of the mixture, containing the tubular fragments, flowed on The two fractions could then be assayed separately for their renin content So far the highest concentrations had been found in suspension of large glomerular fragments, with a segment of the renal tubule attached to them

New prospects in virology have been disclosed by the discovery of interferon, a compound developed in certain virus cultures which can inhibit the growth of other viruses treated with it Dr D C Burke and Dr Alick Isaacs demonstrated the formation of interferon in chick-membrane media inoculated with irradiated influenza virus, and its subsequent concentration and assay Though its mode of action is still in doubt (it may be an analogue of a protein substance, for which it substitutes in an essential metabolic cycle), it has already been shown capable of arresting the multiplication of several viruses in both in-vitro and in-vivo experiments

RESEARCH IN EAST AFRICA

Working in any country other than his own, the investigator may find himself in difficulty because of variations in local custom and methods An example mentioned in the report[1] of the East African Council for Medical Research concerns the water content of cereal foods if these are prepared by certain methods in vogue among African housewives, they may contain so much water as to make ordinary calculation of nutrient values invalid In other work done at the East African Medical Survey and Research Institute it has been shown that mild hookworm infestations do not affect absorption of food, but the effect of heavy infestations has yet to be investigated Surveys in certain districts showed that about 70% of school children were infected by hookworm, and about 90% by schistosomiasis

The Virus Research Institute has been working mainly on "arbor" (arthropod-borne) infections, and the Leprosy Research Centre (a third of whose cost is borne by the British Empire Leprosy Relief Association) has been conducting a therapeutic trial with diphenylthiourea The absorption of this drug is poorer than that of dapsone, but indications are that it is equally effective, and it has proved "remarkably free from toxic effects", in the 56 patients treated there have been no signs of upset of the liver or hæmopoietic system, and no mental disorder The trial is being extended from the Kenya Medical Department Leprosarium to other centres

The Trypanosomiasis Research Organisation reports the development of methods for keeping the parasites deep-frozen by means of solid carbon dioxide By this means trypanosomes of three species have been maintained in an infective state for seven months, and such properties as drug sensitivity have remained stable Using artificial media, trypanosomes have been cultured from blood in which they were scanty (though the method was not much more sensitive than microscopic examination), but not from cerebrospinal fluid Strains of the parasite have been found to vary much in oxygen uptake There is so far no evidence of a special stage of development of the parasite in the mammal, such as takes place with the malaria parasite, the changes in form in the host's blood are attributed to the action of the host's defence mechanisms Infection does not reduce the length of life of the tsetse fly

A GREAT AND INVENTIVE SURGEON

A selection[1] of 78 papers by Walter E Dandy has been published as a tribute to one of the greatest surgeons of all time The choice has been made in chronological order, beginning with accounts of Dandy's work on the blood- and nerve-supply of the pituitary body This work was carried out at the suggestion of Harvey Cushing, who was working in the "Dog House" (laboratory) at the same time as Dandy Dandy's work on infantile hydrocephalus and the circulation of the cerebrospinal fluid is included, it was his first great contribution to surgery and gave him international recognition Halsted, Dandy's chief, said of this feat, "Dandy will never do anything equal to this again Few men make more than one great contribution to medicine" According to Dandy himself it was something to do with publication of this work that led to a violent quarrel with Harvey Cushing The book is specially valuable for its reprint of the epoch-making article on ventriculography, published in July, 1918, while Dandy was still a resident (surgical registrar) The following year his work on air encephalography appeared

There has never been a more inventive surgeon than Dandy, and anyone on the point of claiming to have found something new should first inquire whether Dandy has written something on the subject Indeed, this book may serve to stay the hand of some enthusiastic writers It was Dandy who showed that total removal of acoustic tumours, provided the interior is first removed, gives better results than the intracapsular method of Cushing, and five years before the famous paper by Mixter and Barr, he described protruded lumbar disc as a cause of acute pressure on the cauda equina ("This lesion offers a pathological basis for cases of so-called sciatica, especially bilateral sciatica The lesion is cured by operative removal of the cartilage") Dandy was also the originator of sensory-root section of the trigeminal nerve through the posterior fossa, although his observations about the arrangement of the pain fibres are probably invalid He clearly defined glossopharyngeal neuralgia and cured the condition by intracranial division of the glossopharyngeal nerve But perhaps one of his most remarkable accomplishments was his successful clipping of the neck of an aneurysm of the internal carotid artery, sans angiography, sans electro-cautery, sans blood-bank, sans hypothermia, and *sans peur*

---

[1] The East African Council for Medical Research Annual Report, 1956–57 Nairobi 1958 Pp 20 4*s*

[1] Selected Writings of Walter E Dandy Editors Charles E Troland, M.D., and Frank J Otenasek, M D, Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications *1957 Pp 789 112s 6d*

His article on spasmodic torticollis has not stood the test of time and should not have been included Dandy advocated intradural section of the sensory and motor roots of the first three cervical nerves bilaterally and section of both spinal accessory nerves in the neck, a procedure now abandoned by most neurosurgeons It would have been better to have included Dandy's work on tumours and cysts of the third ventricle. Some of the references are not fully quoted according to present-day conventions For the sake of the younger neurosurgeons and neurologists, a short biography might have been included

The authors and publishers are to be congratulated on the production of this valuable book

---

University of Cambridge

On May 10 the following degrees were conferred

M.B , B Chir —W B Peeling, E. A. French.
M.B —R. A. Aiken (by proxy)

University of Sheffield

The following appointments have been made

Dr P F Harris and Dr Miles Taylor, lecturers in anatomy, Miss E L Jervis, lecturer in physiology, Dr J A Beardmore, assistant lecturer in genetics, Dr Geoffrey Haigh, demonstrator in anatomy, Dr Margaret Platts, honorary lecturer in medicine, Dr Derek Hobson, honorary lecturer in bacteriology, Dr J P P Bradshaw, clinical teacher in neurology, Dr W L. Tonge, clinical teacher in psychiatry

Royal Society

On Thursday, May 29, at 4.30 P.M at Burlington House, Piccadilly, London, W 1, Group-Captain W K. Stewart will give a lecture on the Institute of Aviation Medicine

British Society of Immunology

The next meeting of this society will be held at the National Institute for Medical Research, The Ridgeway, Mill Hill, London, N W 7, on June 13 and 14 The meeting opens on Friday, the 13th, at 1 45 P.M., with a symposium on gammaglobulin and antibodies, when Sir Charles Harington will be in the chair Further details may be had from Dr R. G White London Hospital, E.1

Discussion on Shock

The Faculty of Anæsthetists of the Royal College of Surgeons of England will hold a meeting on Saturday, June 14 at 10 A.M at the college, Lincoln's Inn Fields, London, W C.2, on shock and allied phenomena The speakers will be Sir Henry Dale, Prof W D M. Paton, Dr J B Wyman, Dr R. I S Bayliss, Mr Ruscoe Clarke, Dr L J Wolfson, and Dr R. I Bodman.

Chelsea Clinical Society

In the mountains of Albania Mr Julian Amery, M.P , was treated by a doctor aged 105, who had ridden for an hour to find him. At the annual dinner of the Chelsea Clinical Society on May 13, he spoke of his medical attendant's belief that we are moving into an era when everyone will live longer—about 200 years, the doctor thought. Mr Amery was hopefully interested in the reactions of Cabinet Ministers who found themselves in power for terms of 20 years rather than 5

Sir Walter Fergusson Hannay, the president, described the society as flourishing it has 283 members and has set its limit at 300 In the past year members had paid a visit to the crypt of St Bride's in Fleet Street, had heard talks on getting pleasure from painting, on nuclear warfare, and on the future of the independent school, and had held a clinicopathological conference Dr H S Pasmore, proposing The Guests, quoted Mr Aneurin Bevan on the folly of trying to make a good speech people expected a better one next time, and one's reputation was ruined The Earl of Halsbury replied to the toast

Inaugurating the new president, his predecessor said that, as secretary for 18 years, Dr Harry Coke was more than anyone responsible for the society's resuscitation after the war Dr Coke said that, on the contrary, the real resuscitator was Dr Desmond Macmanus, who had been president longer than anyone else He divulged that the salmon which had lately fed the entire company was caught by Sir Walter himself, in the Spey

Commonwealth Trans-antarctic Expedition

The Queen has approved the awards of the Polar Medal to the following doctors for good services as members of the expedition

Clasp to the Polar Medal —G W Marsh
Polar Medal —Rainer Goldsmith, A. F Rogers.

Women Candidates Only

Dr Marjory Keith, senior registrar at the Bruntsfield Hospital, Edinburgh, has been appointed to the post of consultant physician to the Bruntsfield and Elsie Inglis Hospitals which has been vacant since Dr Margaret Martin's retirement at the beginning of 1957 The South-Eastern Regional Hospital Board's proposal to join Dr Martin's post to vacancies at the Deaconess and Longmore Hospitals and advertise the combined post as open to a man or woman aroused controversy in Edinburgh which ended in ten women bringing a case before the Court of Sessions to restrain the board from appointing a man (see *Lancet*, 1957, ii, 1072) Lord Walker granted an order that no man should be appointed until the post had been advertised for women applicants only

Dr Keith's appointment, like Dr Martins, is at the Bruntsfield and Elsie Inglis Hospitals The vacancy at the Deaconess and Longmore Hospitals has been filled by the appointment as consultant physician of Dr R F Robertson senior registrar at the Edinburgh Royal Infirmary

New Atomic Safety Committee

Sir Douglas Veale, late registrar of the University of Oxford, is to preside over a committee set up by the United Kingdom Atomic Energy Authority to advise on training in radiological protection. This committee, whose members include Sir Ernest Rock Carling, Prof W V Mayneord, and Prof B W Windeyer, will advise the Authority on the training and provision of specialist health and safety staff, not only for the Authority's own purposes but also to meet the needs of the nation as a whole Sir Alexander Fleck's Health and Safety Committee, whose report was published last December, thought that the Authority should assume responsibility for building up the supply of the specialist health and safety staff required as the uses of atomic energy become more widespread Steps have been taken to build up the staff and recruitment is in progress

Hospital Progress

When he opened a new outpatient department at Nottingham City Hospital on May 16, Mr Derek Walker-Smith, the Minister of Health, said that as part of the Government programme of large centrally financed schemes, some 80 hospital buildings were in progress or had been selected for planning Among these 6 new hospitals had been begun, and 10 were at various stages of planning By the end of 1958–59 schemes which would cost about £30 million would be in progress Hospital boards also had schemes of their own choosing, from the money allocated to them, and there were some 45 further schemes of this sort in progress or proposed, costing more than £100,000 each, as well as many more smaller schemes But one of our chief aims, the Minister said, was to keep the patient, if possible, out of a hospital bed altogether, or, if he had to have a spell in one, to get him out of it as soon as this could safely be managed Mr Walker-Smith was glad that Nottingham, and soon Sheffield, were to have new outpatient clinics for these were important means of achieving his aim. Outpatient clinics helped in both, by undertaking diagnosis and treatment that would formerly have needed admission as an inpatient, and by providing follow-up care and supervision, which allowed a patient to go home after a short stay in hospital This shift of emphasis from inpatient to outpatient treatment not only led to a fuller and more economical use of expensive hospital service It was also of social benefit because, as Mr Walker-Smith pointed out, "people do not normally like to have to stay—especially for a long time—even in the best and most comfortable of hospitals and therefore the substitution of outpatient for inpatient treatment, and shorter stays in hospital, are likely to be of great social benefit both to the patient and his family"

Royal Air Force Appointments

Prof J B Kinmonth has been appointed honorary civil consultant in peripheral vascular surgery to the Royal Air Force Wing-Commander R S Peill has been appointed senior medical officer at the Royal Air Force College, Cranwell

Society for Relief of Widows and Orphans of Medical Men

The report of this society for 1957 shows that the membership now stands at 147 and that 25 widows and 2 orphans received grants During the year the society distributed £4000, including £2500 from the Brickwell fund At the end of the year the market value of the society's investments was £107,000 and during the year £2650 savings bonds 3% 1960/70 were bought The president is Sir Robert Young and the address is 11, Chandos Street, London, W 1

Social Security Agreement with Belgium

The convention on social security between the United Kingdom and Belgium, which was signed in May, 1957, has now been ratified and will come into force on June 1 It covers cash benefits for unemployment, sickness, maternity, old age, widowhood, orphanhood, industrial accidents and diseases, death, and family allowances Medical benefits under the Belgium health insurance scheme will be available to citizens of the United Kingdom who are employed in Belgium and to certain other people who are normally resident there

Gairdner Charitable Foundation

This Foundation, which was incorporated last year in Ontario, derives its funds from the gifts of Mr J A Gairdner, a Canadian industrialist and financier, and members of his family It has established the following international awards

Gairdner Foundation award of merit—A prize of $25,000 to be awarded not more than once in every four years to the individual or group of individuals who has made the most outstanding discovery or contribution in the fields of the arthritic, rheumatic, and cardiovascular diseases

Gairdner Foundation annual awards—A series of prizes of $5000 each to be awarded in any one year to not more than five individuals who have made outstanding discoveries or contributions in the same field

The first awards will be made during 1958, and further particulars may be had from the Foundation, 320, Bay Street, Toronto, 1, Ontario The medical advisory committee includes Prof R F Farquharson

---

Dr E C Warner has been elected to the senate of the University of London as a representative of the faculty of medicine

Miss K A Raven has been appointed chief nursing officer at the Ministry of Health in succession to Dame Elizabeth Cockayne

Prof A D Macdonald, who is chairman of the Franco-British Pharmaceutical Commission, is leaving for France on May 22 to lecture at the Faculty of Pharmacy at Strasbourg and the Faculty of Science at Besançon

The Biochemical Society will hold a meeting in the Department of Biochemistry, Tennis Court Road, Cambridge, on Tuesday and Wednesday, June 24 and 25

Letters to the advice department of the Family Planning Association should once more be addressed to 64, Sloane Street, London, S W 1 The advice fee has been increased to 2s 6d

A working group in industrial health will form part of the 1958 summer school organised by the Central Council for Health Education at Bishop Otter College, Chichester, from Aug 19 to 29 Dr S F M Cressall will be tutor to this group

A travelling seminar, which has been arranged by the World Health Organisation, will visit France and England from May 19 to June 7 to study industrial medical services It will be led by Dr J J Gillon, senior medical inspector of factories of the Ministry of Labour in France, and Dr K Biden-Steele, deputy senior medical inspector of factories of the Ministry of Labour in England

The National Society of Non-Smokers held its first London clinic for the cure of tobacco-smoking on May 14, at Caxton Hall, Westminster, at 7 30 P M Dr Lennox Johnston, Dr Norman Macdonald, and Dr Wilfred Lester addressed the 60 smokers who attended The smokers were then split into groups for group psychotherapy Further clinics will be held on June 25 and July 9 at the same place and time

Diary of the Week

MAY 25 TO 31

Tuesday, 27th

POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W 12
4 P M Dr J K Oates Reiter's Disease
INSTITUTE OF DERMATOLOGY, Lisle Street, W C 2
5 30 P M Dr G C Wells *Use of Steroids in Dermatology*
INSTITUTE OF OBSTETRICS AND GYNÆCOLOGY
3 P M (Hammersmith Hospital, Ducane Road, W 12) *Prof J L Wright* (Otago) Anatomy of Prolapse
INSTITUTE OF CHILD HEALTH, The Hospital for Sick Children, Great Ormond Street, W C 1
5 P M *Dr G M Guest* (Cincinnati) *Studies of Insensible Weight Loss.*

Wednesday, 28th

ROYAL *SOCIETY* OF *MEDICINE*, 1, Wimpole *Street*, W 1
5 P M *Endocrinology* Dr Oswald Savage, Mr Geoffrey Slaney, Prof E G L Bywaters Complications of Long Term Steroid Therapy
POSTGRADUATE MEDICAL SCHOOL
2 P M Dr C H Andrewes Influenza—Asian and Otherwise
INSTITUTE OF DISEASES OF THE CHEST, Brompton, S W 3
5 P M Dr J R Bignall Course of Carcinoma of the Lung
INSTITUTE OF OBSTETRICS AND GYNÆCOLOGY
9 45 A M (Queen Charlotte's Hospital, Goldhawk Road, W 6) Professor Wright Toxæmia and Eclampsia in New Zealand
INSTITUTE OF DERMATOLOGY
5 30 P M Dr R T Brain Electrotherapeutic Techniques

Thursday, 29th

POSTGRADUATE MEDICAL SCHOOL
4 P M Dr Sheila Sherlock Hepatic Coma
INSTITUTE OF DERMATOLOGY
5 30 P M Dr Arthur Tickner Epidermal Proteins
HONYMAN GILLESPIE LECTURE
5 P M (Anatomy Theatre, University New Buildings, Teviot Place, Edinburgh) Prof Ian Aird Clinical and Operative Surgery of Parathyroid Tumours
UNIVERSITY OF ST ANDREWS
5 P M (Queen's College, Small's Wynd, Dundee) Prof Sir Stanley Davidson Megaloblastic Anæmias, with special reference to their Neurological Complications

Friday, 30th

ROYAL COLLEGE OF OBSTETRICIANS AND GYNÆCOLOGISTS, 58, Queen Anne Street, W 1
5 P M Dr J S Scott Pregnancy Toxæmia Associated with Hydrops Fœtalis, Hydatidiform Mole, and Hydramnios (William Blair Bell lecture)
ROYAL SOCIETY OF MEDICINE
5 P M Pædiatrics Dr A Doyne Bell The Force of Habit in Childhood. (Presidential address)
8 15 P M *Obstetrics and Gynæcology* Dr G R Osborn, Dr A E Claireaux, Dr Jean Smellie Neonatal Deaths
POSTGRADUATE SCHOOL OF MEDICINE
10 A M Mr E R Frizelle Thoughts and Impressions in Gastro-duodenal Surgery
ST MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W 2
5 P M Mr C W A Kimbell Carcinoma Corporis Uteri
GUY'S HOSPITAL MEDICAL SCHOOL, London Bridge, S.E 1
5 P M Dr H B Cott Protective Coloration in Animals (Fison lecture.)

Appointments

AUNGLE, P G, M B Edin, M R C P E, D P M consultant psychiatrist, Dundee Mental Hospitals
CUSACK, ANNE L J, M B Dubl, D P H assistant M O H, north-eastern area, Warwickshire

Birmingham School Health Service

CARVILL, P B, L R C P I M O
MARSHALL, BARBARA S M, M B Birm M O
VILLIERS, G I L, M B Dubl M O

London County Council

GRAEME, M L M B Cantab, D P H M O
MAHON, T J, M B N U I, D C H, D P H M O
ORTON, W T, M B Belf, D P H M O
WATTON, R W, M B Lond, D P H M O

Colonial Appointments

AUDEN E F, M B Edin M O, British Honduras
CARAPIET, A M, M B Calcutta M O, Somaliland
CHUNG HONG WING C C, M B N U I M O, *Mauritius*
DAS, J B, M B Madras, F R C S M O (grade B), Trinidad
MCGOWAN, ANGUS, M B Glasg M O, Hong Kong
MCLAREN, ROBERT, M B St And, D P H M O, Trinidad
MARCHANT, D E, M B Lucknow, D P H M O (grade C), *Trinidad*
TAYLOR, R J, M B Leeds M O, Tanganyika

The name of the Association of British Insecticide Manufacturers has been changed to the Association of British Manufacturers of Agricultural Chemicals

Semi-permanent exhibitions will be held at the Institute of Dermatology, Lisle Street, London, W C 2, during the summer term The first, from June 2 to 30, will be by Dr R W Riddell on skin reactions to fungus antigens

The Lancet · Saturday 31 May 1958

TIME AND THE NERVOUS SYSTEM *

THE BRAIN AS A CLOCK

WILLIAM GOODDY
M.D Lond., F.R.C.P
PHYSICIAN TO THE NATIONAL HOSPITAL, QUEEN SQUARE, AND TO UNIVERSITY COLLEGE HOSPITAL, LONDON, W.C.1

> "We know how dangerous it is to over-estimate intuition Let us first ask a simple question What is a clock?"
>
> EINSTEIN and INFELD 1947

THOUGH present-day civilisation depends to a great extent on the administration of time (Government time), through the use of clocks, for its social and scientific progress, there is no *system* of knowledge about time, to compare with the advanced systems of biology, physics, and chemistry In neurology, which lies at the junctional point of philosophy and science, our interests have, until now, been limited to the spatial aspects of our subject We have therefore constructed the principles of clinical neurology, neuroanatomy, and neurophysiology in terms of space, thus

Clinical Neurology

Localisation of lesions
Representation of functions
Attribution of normal functions to parts, when symptoms follow damage therein
Reflexological tests concerned with "levels" in the nervous system

Neuroanatomy and Neuropathology

The spatial extensions of nervous tissues
Detection of disease processes by deduction from the state of tissues after removal and chemical processing

Neurophysiology

The operational study of isolated nervous structures according to theories derived from contemporary (electrical and chemical) technology.

The dramatic fragments of *temporal* neurology are treated as curiosities, or relegated to the neglected interstate between neurology and psychiatry For example, *amnesia* (from head injury, intoxication, epilepsy, encephalitis, or intravenous anæsthesia), the meaning of the alpha-rhythm of the electroencephalogram, and the "deja-vu" sensation of uncinate epilepsy, are all unrecognised as signposts in the exploration of the time sense.

There is now a worldwide awakening of interest in the problem of time and times Neurology is in the best position for the investigation of disorders of the time sense, and for the coordination of work in the fields of behavioural physiology and anatomy, navigation, electronics and computers, and "automation" generally

This contribution is a *summary* of thought on the human time sense, derived from clinical study To understand the main proposals of this work—that (1) animals contain immense numbers of clocks, from which the nervous system transmits and registers the time information, and that (2) the nervous system itself is a very complex clock-system—one must first consider the principles of chronometry

Chronometry

Definition of a Clock

The following definitional comments of clock forms are provided by Einstein and Infeld (1947)

"The primitive subjective feeling of time flow enables us to order our impressions, to judge that one event takes place earlier, another later But to show that the time interval between the two events is 10 seconds, a clock is needed By the use of a clock the time concept becomes objective Any repeated physical phenomenon may be used as a clock, provided it can be repeated as often as desired Taking the interval between the beginning and the end of such an event as one unit of time, arbitrary time intervals may be measured by repetition of this process All clocks, from the simple hour-glass to the most refined instruments, are based on this idea"

A definition of the strictest kind, expressed in the language of scientific logic, has been provided for me by Prof J H Woodger

"R is a clock if and only if R is an A-line, every member of the field of which has the same duration as any other member, and the beginning and end in time of every member of the field of which is visible, audible or palpable"

It is exceptionally important to note that no clock mechanism fulfils its purpose as a clock unless its activity is perceived by an observer, who understands the manner in which the clock possesses the attributes of a timekeeper

The clock of everyday use consists of a powered mechanism, driven by a coiled spring, or weight and pendulum (their power derived from the person who winds them) or electricity Two principles are used

1 The continuous motion derived from the power source is broken up into intermittent motions of regular form, providing equal periods between each motion, the moment of ending of one motion exactly coinciding with the moment of beginning of the next.

2 The number of these periods is counted

Continuous to Intermittent Motion

A device known as the "escapement" permits the escape of movements of the clockwork, each of the same duration This movement takes place in the train of gearwheels between the power source and the hands of the clock, so that by suitable gear ratios the turning of the wheels and the hands of the clock represents for the observer the Earth's rotation about the sun The escapement also provides the energy which keeps its own mechanism in rhythmic action Gould (1923) expounds the history and principles of chronometry

We find in the nervous system an exactly similar process, in which some *continuous* performance, such as movement or sensation, is transmitted by an *intermittent* process The example of nerve action-potentials serves to illustrate this point

Counting and Recording the Number of Escaped Cycles

The counting apparatus is provided by the passing of "hands" over the "face" of the clock, which provides, in its marked subdivisions, *intervals of space equivalent to intervals of time* Thus in the clock we have the equation of time with space Following this statement, we reach an exciting conclusion, for we find that

> Man, being equipped psychologically with a sense of space and a sense of time, may be considered physiologically as a clock system

Neurological Aspects of Chronometry and Navigation

The methods by which human beings relate themselves to their surroundings were outlined in previous papers (Gooddy and Reinhold 1952, 1953, Gooddy 1957a) The evolution of the neuroanatomical and neurophysiological techniques by which we are able to live purposefully in a three-dimensional environment was considered Suggestions of the importance of a fourth-dimension or time factor were outlined In the second paper (1953) the notion of "motion-sense" was introduced The breakdown of "motion-sense" in disease of the nervous system was illustrated by clinical tests of language, visual, auditory, and tactile perception, spatial judgments awareness of the significance of direction, constructional and navigational performance

---

* From two lectures delivered at the University of California Medical Center, Los Angeles, Department of Physiology, November, 1957

The human faculty of finding one's way about (navigation), of realising the relations of parts of the body one to another, and of appreciating the interrelationships of objects of which one is only theoretically aware (e g, molecular structure of chemical compounds, geography, astronomy) has been developed for the needs of progress and survival to such a degree of perfection that these "functions" are relegated to subconscious level, except

1 In situations which are new (and therefore exceptionally difficult)—e g, finding one's way about in a strange place, especially in a foreign land without previous personal landmarks, and where the language is not understood There are then the equivalents of spatial disorientation and dysphasia Or in developing a new skill, such as touch-typing or the understanding of spherical trigonometry

2 In disease of the nervous system

In the papers mentioned above, it was also shown that the passage of time is essential for perception—that unless it is possible to say, for example, "I am not being pricked by a pin, I am being pricked by a pin, I am not being pricked by a pin" there can be no full or accurate description of the perception (and memory) of having been pricked by a pin

If the ideas so far expressed are accepted, we may make a statement of personal chronometry from clinical observations of personal navigation

Since (1) we are able to achieve personal navigation (spatial orientation), and since (2) the awareness of the passage of time is as essential for perception as the knowledge of the extensions of space, *we must be equipped with internal chronometric apparatus amenable to physiological analysis*

The Internal Clocks

We may now proceed to investigate the proposal that there are internal clock forms, which enable us to have a "sense of time", without using such external means as require the perception of a mechanical device

To prove that this proposal is true, it is necessary to show that there are systems or "mechanisms" in which are produced the exactly repeatable physical phenomena

The body does contain a large number of such "mechanisms", of which some are obvious and of special importance Others, of equal or greater importance, are less obvious The principle underlying their functions as clocks may be once more outlined *All that is necessary for a clock is "the detectable phenomena of accurate repetition"* The greater the accuracy of repetition, the greater the accuracy of the clock Extreme refinements of accuracy are provided from measurements of the motions of the *very large* or *very small* bodies The most accurate time measurements at present are derived from

1 The motions of the stars (bodies of immense size, remoteness, and speed of movement relative to the earth)

2 The vibrations of quartz crystals (100,000 oscillations per second)

3 The motions of the molecules of ammonia gas or cæsium (also showing striking contrast of size and speed compared with the earth)

That the human being through his body may have some "awareness" of molecular activity has been suggested (Gooddy and Reinhold 1953) We have, between our observations of the motions of heavenly bodies and the possible subconscious reckonings of molecular activities, the set of clocks now to be described It is to be noted at the outset that the patterns of clock mechanisms are so diverse that there should be a diversity of times recorded From this multiplicity of "times" may be derived the concept of "Time" that is, the average of physiological times is equivalent to "mean psychophysical time"

Physiological Clock Mechanisms

There are two main groups to be considered

1 The non-nervous organs and systems which have a rhythmic pattern of activity

2 The nervous mechanisms which transmit the impulses from which the action of non-nervous organs is detected Note —These nervous mechanisms themselves show rhythmic activity, which provides temporo-spatial patterns in the nervous system Such "dynamic patterns" may provide a link between physiologically demonstrable nervous activity and perception (Gooddy and Reinhold 1954, Gooddy 1956, 1957*a*)

Summary of non-nervous organs and systems showing rhythmic activity —There is some difficulty (artificiality) in defining this group, for every bodily structure is in some degree under nervous control, in that its activity is modified by action of the nervous system Such organs as the heart (which shows rhythmic activity of an obvious kind) ultimately depend on a number of local and general nervous (and neurochemical) mechanisms, from the branches of the bundle of His to the very complex cerebral modifying mechanisms (Gellhorn 1953) The heart-rate may vary from 40 to 160 beats a minute under cerebral influences Similarly the lungs, the bowel, the bladder, and the glands may vary in activity according to nervous activity

However, the point for present demonstration is that there are many bodily structures, not themselves nervous structures, which have *rhythmic activity* fulfilling the requirements of repetition necessary for a clock form We have also to consider those *rhythmic processes* (respiration, pulse, temperature, for example) which emerge as the most important consequences of the activity of rhythmically acting organs (heart, lungs)

Cardiovascular System
  Muscular activity
  Pulse transmission
  Nervous control
  Biochemical effects

Cerebrospinal-fluid System
  Two forms of pulse—cardiac and respiratory

Cardiorespiratory System
  Rhythmic neuromuscular activity controlling and controlled by biochemical adjustments in blood and tissue metabolism

Alimentary System
  Rhythmic activity of alimentary tube, from pharynx to rectum, associated with regular intake and output Glandular activity closely associated (e g, blood-sugar level)

Cardiorenal System
  Regulated output of soluble material in delicately adjusted volumes of fluid

Glandular and Autonomic Systems
  Growth, generation, gestation Regeneration Maintenance of standards, e g, metabolism, temperature Relation to mental states Healing Effect on size of body, development and age. Sexual cycles, male and female

From this rough classification, examples from the cardiovascular system may be used to provide illustrations

The Heart and Blood-vessels

The arterial pulse has, from antiquity, been noted for its generally regular rhythm under steady conditions The circumstances producing acceleration and deceleration to raised or lowered levels (tachycardia, bradycardia) or altered rhythm are common knowledge, popularly connected with the emotions Their description may be found in any textbook of medicine, cardiology, or pharmacology, as well as in works on psychology, and in poetry and non-medical prose, including the Bible There is, for any individual, an approximately steady rate—usually, during rest, between 65 and 75 beats a minute The average or "normal" pulse-rate is usually given as 72 a minute When Galileo in 1590 made his observation of the swinging lamps in the cathedral of Pisa, which led to his formulation of the principle of the pendulum (i e , that each swing of a freely suspended body takes the same time as any other, independently of its length or arc of swing) he is said to have used his pulse for a method of timing It says much for the detachment of scientific observation if at such a time of fundamental discovery Galileo's pulse remained steady

The physician detects the cardiac and arterial pulses by sight, touch, and hearing Technical devices are often used to magnify the fundamental rhythmic processes, which are associated with two distinct forms of appreciability

1 The local and distant effects of rhythmic contraction and expansion of muscular tissue (which may be detected in transmission either along the arterial wall or other tissues (heart apex-beat, abdominal aortic pusaltion), or felt by application of some part of the observer's body—usually the finger or palm)

2 The mechanical production of sounds, (*a*) by fluctuations of pressure in a valve-controlled tubular system, or (*b*) by muscular contraction directly In the first group we have the heart sounds in pairs, accompanying normal systole and diastole, the rumblings of abnormal confluences of blood, as in valvular disease of the heart (mitral stenosis in rheumatic heart-disease, or in arteriovenous communications (cerebral angioma) In the second group we have the accessory heart sounds

In health and daily life, we are not usually conscious of the heart's action, nor do we often make any form of analysis of it Nevertheless, the information is always available and is constantly presented to and by the nervous system, by the above-outlined methods, as well as in the well-established nervous channels leading directly from the organ The study of cardiovascular physiology and disease objectifies many of the details of the arterial pulse system

We find, therefore, that in the cardiovascular system there is a well-defined system of clocks Certainly this system is liable to frequent and considerable modifications of action leading to alterations in the time-values derived from the system However, over an extended period, such as a day or a week, a person will have a fairly steady average pulse-rate A person engaged in ordinary routine work of a sedentary type is likely to experience pulse-rates between, say, 65 and 85 a minute, with a mean value of about 72 a minute The brief periods in which he may be in a rage or frightened, or running for a bus, will be accompanied by an increased pulse-rate, but this peak-period, unless prolonged, will make little difference to the average over the twenty-four hours

In several conditions a high average pulse-rate may be maintained for long periods (anxiety, fever, thyrotoxicosis, heart-failure, paroxysmal tachycardia, intoxication) We have to ask ourselves whether such conditions are associated with alterations in some part of the time-sense It can be shown that such alteration does take place, though it is often unrecognised subjectively (i e , by the patient) until his health returns to normal, when he is able to have another (normal) time-sense to compare with the former

Rhythmic Activity in the Nervous System

We have now to consider what may be a new proposal about the nervous system and its activity The proposal is formulated thus

1 Because of its fundamentally rhythmic type of activity (associated with the "all-or-none" phenomena), at all neurophysiological levels,

2 Because the nervous system mediates sensory and motor activity, and thus is completely integrated with the reception and creation of rhythmic phenomena (e g , light and sound waves, habitual movements, such as walking, breathing),

3 Because the nervous system is the final mediator of the person's awareness of all the clock systems derived from rhythmic systems not primarily nervous,

4 Therefore the nervous system provides both the anatomical structure and the physiological activity essential for clock mechanisms, and *may be regarded as a clock*

If we accept the notion of the nervous system as a clock, we note immediately the complex nature of its structure The final clock, by which perhaps we say we "know about time", is the last abstraction of the innumerable subsidiary clock forms In neurophysiological terms, the alpha rhythm of the electroencephalogram shows the final abstraction from all other rhythms Rhythmic activity has been demonstrated in a single cortical cell (Phillips 1955)

Some important systems will now be briefly discussed

The Intrinsic Activity of Nervous Tissue

The basis of nervous activity is the transmission of the nerve impulse, which is the unit used by Eccles (1953) in his attempt to discover *The Neurophysiological Basis of Mind* The nerve impulse is used also by Katz (1952) as the fundamental unit of nervous activity Nerve-fibres have (*a*) rates of "firing," depending on the rate of stimulation and the refractory period, and (*b*) rates of transmission, depending on fibre cross-sectional area

Therefore, for habitual activity (whatever it may be) which we train ourselves to perform, there is a habitual rate of sensorimotor activity, which may be expressed in neurophysiological terms as habitual rates of firing and conduction along nerves This habitual rate of activity derived by abstraction from an infinity of activities, provides a very steady clock system at all levels, because of the reliability of "averaging" which is possible in a system composed of such immense numbers of units

The structure of the nervous system is well fitted to such a design for function, and differs from the cardiovascular system, which relies not on abstraction but on simple bulk transport (the blood-channels enlarging progressively towards the heart, which is conventionally regarded as the centre of the system) (Gooddy 1957b)

The Autonomic System

Inseparably linked with the clock systems classified as "non-nervous" is the autonomic nervous system, which traditionally holds a much neglected position in neurological study Only when the autonomic system is functioning normally can the individual make use of his *voluntary nervous system* *Only when the rates* of functioning of those metabolic systems which maintain life and health are normal does living matter (human being or plant or single cell) prosper

The autonomic system is the controlling device of innumerable neuro-anatomico-humoral systems, which are *set* in certain positions of adjustment according to the state of the individual These adjustments may be altered singly, or (in certain groups) totally They are so interconnected that it is not possible for one to be altered without an effect upon others, this relationship being the basic " mechanism " of homœostasis Simple examples may be seen in the chemico-neuro-chemical alteration of heart-rate during exercise, and the photo-chemico-neurological response of the pupil to light and shade Such adjustments are linked to change of state, and vary according to the degree of change (up to the limits of the system's performance if the limits are exceeded, pain and disability or disease result)

Thus we find that the autonomic system is compounded of many clock systems, which control (and are mutually controlled by) those " vegetative " processes essential for life The autonomic system provides the regularity of rhythms essential to volitional activity it is the nervous system of rhythmicity Its clock faces may be seen in countless forms Examples are shown in records of pulse, respiration, and temperature, in menstrual cycles, in uptake of radioactive isotopes, in photographs of a person in infancy, childhood, adolescence, maturity, old age When disordered in function, the autonomic system shows clock systems recording abnormally—in fever, pain, tachycardia, colic, and depression

These clock systems are neglected because we are over-familiar with their habitual perfection The *poet*, not the physiologist, knows this neglect, as an extract from A E Housman shows

" When I was off to dreamland
  And left my limbs forgot,
Who stayed at home to mind them
  And breathed when I did not ?"

The Special Senses and " Touch "

The special senses and touch provide a wealth of clock systems, which are to be discussed in detail elsewhere They depend for their clock-like activity on certain principles

1 They may be concerned directly in " reporting " from other clock systems, either specially designed and constructed to affect them—e g , the ordinary clock-face or watch-face (vision), and the chiming of clocks or the reception of verbal and electrical signals (hearing)—or naturally available in the world environment—e g , motions of stars, state of vegetation (vision), bird song, insect sound especially in tropics (natural auditory clocks are fewer than visual ones), ripeness, decay, perfection of cooking (taste and smell), arrival in harbour (balance), seasonal warmth or cold, ice, dust, drought (touch and thermal sense), passage of vehicles (vibration)

2 They provide information of external physical activity to which they are specially " tuned " The visual system distinguishes various *speeds* and *intensities* of light waves, the ear, various speeds and intensities of sound waves In so doing, sight and hearing provide the proof of their clock-likeness, because, for example, to distinguish between two musical notes, the auditory system has to differentiate rates of vibration *per second* (or any other time unit) Thus in music, pitch and " tune " are two obvious clock systems

The touch system is " tuned " to molecular activity (Gooddy and Reinhold 1953) as shown, for example, by our capacity to appreciate contact and distinguish differences of *hardness*

The " chemical " senses, smell and taste, provide judgments of rates of solubility and degrees of concentration

3 They *provide, without mechanical clocks*, each in its own modality, evidence of time passed and so the possibility of judging age The final perception of a modality is often expressed in time judgment " His face was so changed, he must have been in the last stages of his illness " (vision) " That engine is very ' rough ' it must be years since it was overhauled " (hearing) " That cheese is over-ripe " (smell) " This is the 1890 port " (taste) " That cloth was quite worn out " (touch)

4 They are concerned with order, or sequence The meaning of spoken and written words, and of mathematical symbols, and especially of musical notation, tunes, and harmony, depends on " navigation " of muscular and skeletal instruments (vocal apparatus, fingers, and pen) *Thus writing consists of a temporal* sequence of variously directed lines Phrases are meaningless without correct time sequence

5 They create some of the common units of nervous activity (nerve impulses) which, by their *temporal* as well as spatial patterns, provide a basis for perception (Gooddy 1957a)

The Locomotor Systems and Posterior Columns of the Spinal Cord

The locomotor system is here considered to consist of all the bodily apparatus necessary *for the directed movement of the limbs, the results* of which are known It is the custom, neurologically, to concentrate on the nervous control of muscles, and study " levels " of nervous activity It is equally or more profitable, from the point of view of function, to study the performance of limb segments about the joints which are their fulcra In such studies, we find, in the words of Descartes (*Dioptrique*) a " natural geometry ", which is of the greatest significance because it illustrates exactly, in ways capable of objective description and analysis, the principles of navigation and chronometry already outlined *This matter is to be described* with experimental elaboration elsewhere The points to be made here are

1 Movement is limited by the mechanical properties of joints, which are either of ball-and-socket or of hinge type Naturally we are able to derive compound movements by using the properties of many joints at once For example, in shaking hands there is a setting of the feet and a setting of the trunk upon the pelvis From the position of the hand at rest by the side, there is a slight forward movement of the shoulder-joint (20°) and a much larger movement of the elbow-joint (90°) There are also complex *angular adjustments of the* carpal, metacarpal, and phalangeal joints

2 *Space* traversed by a limb point depends on (*a*) the length of the limb segments and (*b*) the angular velocities of the limb segments about their joint axes

3 *Space* traversed will be deducible from the number of repeated joint movements, if counted

Points 2 and 3 will depend on the fact that

4 Each person has a habitual rate of movement (which can be varied at will, but usually lies closely about a mean value for the person)—e g , speech, walking, eating

We may conclude that *limb movements are clocks* of great importance and of general validity because there is general conformity of human size compared with distances covered Thus most adults are between 5 and 6 feet in height, and can easily manage to cover distances of several miles

The positions of the limb points are the hands of the locomotor clock upon the face of the earth

If there is a great difference of limb length (adult compared with child), and if the locomotor clock system is as important as has been proposed, there should be an appreciable difference of time sense between adults and children which we all know to be true.

Additionally, the larger limb is associated, over the same world distance, with a smaller angle of joint movement, and therefore a smaller angular velocity if the movement from one point to another occupies the same time as that taken by the shorter limb. The alterations of skin and muscle tension and the effects of the weight of the limb also provide "information" of clock-like type. We should not, therefore, be theoretically surprised if the nervous connections subserving the awareness of joint position, movement, muscle sense, and the motional aspects of cutaneous sensibility (touch) were found to be grouped together in the nervous system. (I do not conceal my astonishment at finding, by deduction from the foregoing hypothesis and not from textbook instruction, that the posterior columns of the spinal cord exactly fulfil these theoretical requirements.)

Brain-stem (including Cerebellum) and Thalamus

These regions are traditionally concerned with automatic arrangements to preserve the organism alive and provide the crude information for spatial orientation (especially "balance" and "sight"). The physiological relationships between the posterior-root components (which pass to either the posterior columns or the spinocerebellar (or spinothalamic) tracts) and the brain-stem nuclei and cerebellum are well known.

In providing the data for spatial orientation these regions must, ipso facto, provide temporal data.

In the thalamus are interrelated the sensory data from all forms of receptor, though we presume that at this "level", "discrimination" is impossible. We should expect to find with damage in this region a quantitative disorder of sensation, of a character differing from the qualitative defect found when the cerebral cortex is damaged. The reader may ask himself whether there is such a difference between thalamic symptoms and cortical symptoms. We know that with thalamic lesions there is a "raised threshold" (greater stimulation, an increased *rate*, necessary for detection) and "over-reaction" (pain, *very* painful, hot, *very* hot, pleasant warmth, *very* agreeably warm) and a delayed response.

Note on the basal ganglia.—We are told that the basal ganglia represent the evolutionary reptilian motor system, but we do not know their function in health. Lesions of this system result in alteration of muscle tone and the appearance of rhythmic involuntary movements. The tone defect is accompanied by a *slowing* of limb movement. The involuntary movements are characterised by their regular rhythmic nature. Tremor is a normal finding in healthy people; its rate is about 10 cycles a second. The tremor of anxiety and hyperthyroidism is an exaggerated form of the normal, at the same rate. In parkinsonism, the tremor is slower and coarser than normal. Both normal and abnormal tremors provide a clock system. Some patients with parkinsonism say that time seems to go faster since the onset of the disease, but others say it goes slower. The reasons for this are to be discussed elsewhere.

The Cerebral Cortex

It is generally agreed that those processes or faculties loosely classified under the titles of "memory", "foresight", "judgment", "intelligence", "behaviour", "concentration", "reasoning" are disordered in cases where we find evidence of damage to parts or the whole of the cerebral cortex.

Such processes, for all their apparent diversity, have one common underlying feature—namely, the loss of "timing". Thus when memory fails, we find a defect of recall and arrangement of time past. A failure of concentration is an inability to maintain a "fine-scale" sensorimotor activity ranged immediately about the present. Foresight, judgment and reasoning imply a failure of forward memory or "prediction". When these powers are lacking, it is easy to show that the patient can no longer estimate odds of probability concerning future events on the information available from the past. The patient, with a frontal-lobe tumour or cerebral atrophy, who is incontinent of fæces, has forgotten what it will be like, *in the future*, to have been incontinent. To say that "he does not *care* whether he is incontinent or not" describes accurately the circumstances, for if he were well, he would be horrified, because he recalls from the past that wilful incontinence signifies the breaking of social rules; and rules are formulated to direct future behaviour.

At a neurophysiological level we should expect to find evidence of clock systems, especially if it is accepted (*a*) that the cerebral cortex behaves in a calculator-like way and that "its function is to select, differentiate, condense and abstract rhythms or patterns of neuronal activity" (Gooddy and Reinhold 1954), and (*b*) that perception depends on the spatiotemporal arrangement of nervous activity.

We should be able to deduce, further, that the characteristic feature of the cortical neurophysiological clock should be a simplified rhythm, abstracted from the multitudes of nerve-cells, processes, channels, and impulses.

We see, in the electroencephalogram, the exact illustration of this deduction which (it is important to state) was derived from the hypothesis of this work and not from the admitted long-standing familiarity with the electroencephalograph. The electroencephalogram *is a neurophysiological demonstration at cortical level of the whole theory underlying this paper.*

Conclusions and Summary

This work presents an outline of a new hypothesis, derived from, and especially applicable to, study of the nervous system.

The instruments and discoveries of science are shown to be particular examples of mechanisms already perfected in living creatures. From this it follows that navigation and chronometry, demonstrated in the control of ships and aeroplanes, and the construction of clocks, are but the exteriorised examples of personal navigation and chronometry. We should, then, be able to detect and describe physiological chronometric mechanisms (clocks, clock systems) in the same way that spatial orientational mechanisms have already been described.

Clocks of non-nervous and nervous mechanisms are described. Examples of non-nervous clock-systems are given in a discussion of the rhythmic nature of the heart-beat.

The intrinsic rhythmic activity of the nervous system, in units and as a whole, is emphasised. Neurological clock-systems at various anatomical levels in the nervous system are described.

The electroencephalograph is used as evidence of the highly abstracted cerebral cortical clock-system, and as proof of the theory underlying this paper.

The work leads naturally to a study of disorders of the clock-system, which will form the subject of future communications

I am most grateful to the University of California, Los Angeles, for their generous hospitality, which enabled me to visit the Department of Physiology, and especially to Dr Robert D Tschirgi, associate professor of physiology, at whose invitation these lectures were given

OCCULT INTESTINAL BLEEDING AS A CAUSE OF ANÆMIA IN ELDERLY PEOPLE *

P D BEDFORD
M D Leeds, M R C P
CONSULTANT PHYSICIAN

L WOLLNER
M B Lond, M R C P
LATELY MEDICAL REGISTRAR †

COWLEY ROAD HOSPITAL, OXFORD

ANÆMIA is common in old people admitted to hospital, whatever their salient clinical condition, but is often revealed only by routine hæmatological investigation In the large majority of cases the anæmia is of the iron-deficiency type (Bedford 1952)

The importance of blood-loss in the production of iron-deficiency anæmia has been firmly established for younger age-groups (Moore 1955, *Lancet* 1955) but appears to be insufficiently appreciated as a major factor in anæmia of old age Thus, although Moore (1955) states that " nutrition plays a relatively minor role in the production of iron-deficiency anæmia among adults unless blood-loss also occurs ", Hobson and Blackburn (1953), in their survey of old people living at home, and the *British Medical Journal* (1955) state that iron-deficiency anæmia is due to dietary deficiency and intestinal malabsorption, and virtually dismiss the part played by blood-loss

We intend to show here that, whatever other factors are concerned, occult intestinal bleeding plays an important part in the pathogenesis of anæmia in old people

Material and Methods

The present study is based on 175 patients admitted consecutively to the geriatric unit, Cowley Road Hospital, Oxford Of these patients 19 were excluded either because they had overt bleeding or because they were aged less than 65 and therefore could not be held to be unequivocally elderly The remaining 156 patients with no overt bleeding and aged 65 or more comprised our material Of these 156 patients 61 (39%) were men and 95 (61%) women (table I) This preponderance of females merely reflects the usual preponderance of females over males in the sex ratio of patients admitted to this and similar hospitals All were under the care of one of us, and full clinical examinations were made of all by both of us independently

TABLE I—SEX-DISTRIBUTION OF ANÆMIA IN PATIENTS AGED 65 OR MORE ADMITTED TO HOSPITAL

—	Male	Female	Total
No of patients investigated	61 (39%)	95 (61%)	156
No of anæmic patients (Hb <80%)	25 (41%)	39 (41%)	64 (41%)

Weekly hæmoglobin estimations with the M R C grey wedge photometer (King et al 1948) and blood-film examinations were made on each patient Simultaneously a fresh specimen of fæces, obtained when necessary by digital manipulation per rectum, was examined for occult blood by the Gregersen test (Gregersen 1919) A hæmoglobin level of less than 80% (11 7 g per 100 ml) recorded for any patient at any time was arbitrarily taken to indicate anæmia, this being the same level as that chosen in the Sheffield survey (Hobson and Blackburn 1953) In anæmia as defined, " absolute values " for the mean corpuscular hæmoglobin concentration, the mean corpuscular volume, &c , were determined and, not routinely but in all cases where indicated for diagnosis, further investigation—e g , examination of the marrow—was made The tests for occult blood were recorded either as positive or negative, the former being limited to Gregersen's " strongly positive " reactions (Gregersen 1919), all other results being classed as negative Medicinal iron was not obligatorily withheld, and dietary restrictions were not imposed other than for therapeutic reasons

Results

Anæmia

Of the 156 patients 64 (41%) were anæmic as defined (table I), 34 (22%) having hæmoglobin levels below 75% and 21 (13%) below 70% (table II) More detailed examination of the blood, as described above, proved the anæmia to be of the iron-deficiency type in 60 (94%) of the 64 anæmic cases according to the generally accepted diagnostic criteria described by Whitby and Britton (1953), whatever else was present

Patients are grouped according to age in figs 1 and 2, which show that the incidence of anæmia was similar in all the age-groups over 65, such differences as were present are not significant The gross distribution (fig 1) reflects the number of admissions in each age-group, but, when anæmia is expressed as a percentage in each age-group (fig 2), the incidence is similar throughout the quinquennia over 65

The incidence of anæmia in the two sexes is equal—41% (table I)

These data thus clearly establish that iron-deficiency anæmia is common in patients aged 65 or more admitted to this hospital

Occult Intestinal Bleeding

Examination of the fæces of the 156 patients for occult blood showed positive reactions in 85 patients (55%)

TABLE II—INCIDENCE OF ANÆMIA IN 156 PATIENTS AGED 65 OR MORE ADMITTED TO HOSPITAL

Hb level	No of patients
<80%	64 (41%)
<75%	34 (22%)
<70%	21 (13%)

---

* The basis of a communication to the Medical Society for the Care of the Elderly, Manchester, in October, 1956

† Now senior medical registrar, Sunderland General Hospital

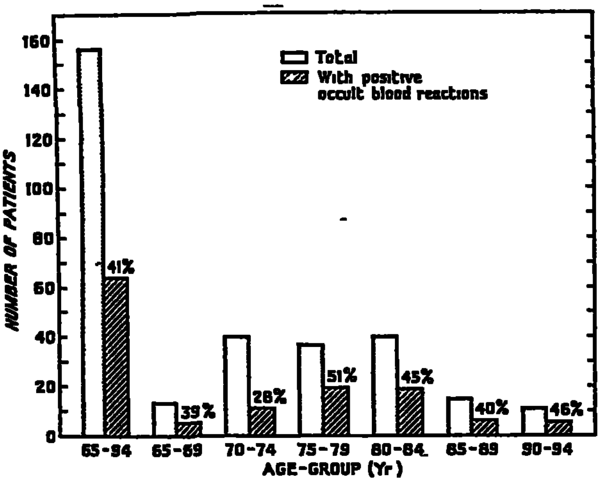

Fig 1—Age-distribution of anæmia

(table III) When the patients are grouped according to age, and the gross distribution (fig 3) is corrected by expression as a percentage (fig 4), the incidence of positive reactions for occult blood is similar in all the age-groups over 65, such differences as are present are not significant

These data thus clearly establish that positive occult-blood reactions are common in patients aged 65 or more admitted to this hospital

Technique of test for occult blood in fæces—For each test a smear of a fresh specimen of fæces is made on a clean new glass slide and viewed against a background of white paper A powder containing a mixture of 25 mg of benzidine hydrochloride and 200 mg of barium peroxide ‡ is dissolved in 5 ml of glacial acetic acid by shaking in a test-tube (the resultant solution thus contains 0 5% of benzidine HCl) The fresh solution of benzidine is poured at once over the fæcal smear A deep blue colour appearing within 15 seconds is the only positive result A blue or a green colour appearing within 30 seconds—Gregersen's (1919) ' weakly positive' result—and no colour, or any colour appearing after 30 seconds are all negative results In this study only the appearance of an immediate blue colour—i e, within 15 seconds—was classed as positive Delayed colour reactions were classed with no colour, as negative Gregersen (1919) accepted all three colour reactions as positives , whereas we followed Needham and Simpson (1952) in limiting our interpretation of positive reactions " as indicated above.

Relationship between Anæmia and Occult Intestinal Bleeding

Of the 64 anæmic patients as defined (anæmic group) 50 (78%) gave positive reactions for occult blood in the stools (table III), whereas of the 92 cases with hæmoglobin more than 80% (non-anæmic group) only 35 (38%) gave a positive reaction on testing for occult blood (table III) This difference is statistically highly significant ($\chi^2 = 24\ 46$, $n = 1$, $P = < 0\ 01$)

These data thus clearly indicate that, in elderly patients admitted to this hospital, anæmia and positive occult-blood reactions are related

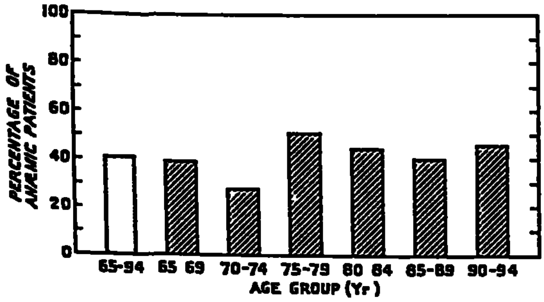

Fig 2—Age-distribution of anæmia.

Validity of Definition of Anæmia

Several published statistics of "normal values" for hæmoglobin levels in elderly people include figures of less than 80% (Wintrobe 1933, Medical Research Council 1945, Olbrich 1947, Shapleigh et al 1952), but it is highly probable that these so-called "normal values" include in their lower ranges figures derived from patients who had hæmorrhage or other blood diseases The fact that the mean "normal values" for postmenopausal women are lower in all the series than those for men also indicates a pathological basis because menstrual loss no longer applies The view of Shapleigh et al (1952) appears to be amply justified

> " the range of minimum and maximal values (i e of hæmoglobin level in old people) is greater than that usually seen in younger age groups which suggests that subjects were included who had diseases other than those common to the ageing process "

Olbrich (1947) similarly states

> " some of the reported figures are so far removed from the ' normal ' as to raise the suspicion that they refer not to the physiologically aged but to patients suffering in old age from a variety of pathological conditions "

Validity of Gregersen's Test for Occult Blood

Gregersen's (1919) test is a modification of the benzidine test (Adler and Adler 1904) A positive result, as defined above, indicates occult intestinal bleeding in virtually all cases, provided that liver and black pudding are excluded from the diet Neither medicinal iron administered orally nor any article of diet other than liver and black pudding (which contain much blood) affects the result. At least 3 ml of blood must be ingested to produce a positive result

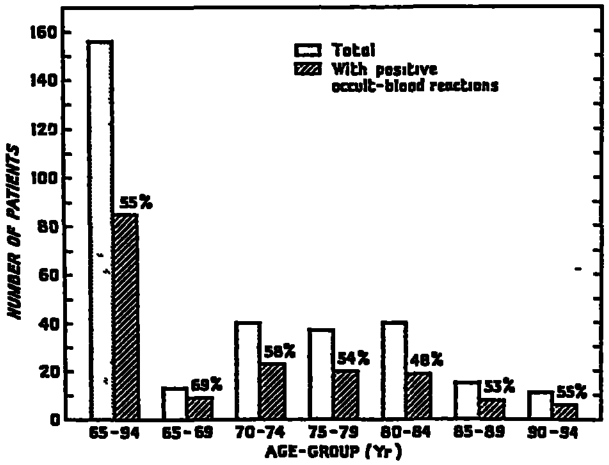

Fig 3—Age-distribution of positive occult-blood reactions

Needham and Simpson (1952), who used this test on 603 unselected outpatients on entirely unrestricted diets, found a source of gastrointestinal bleeding in 88% of all cases with positive reactions for occult blood in the stools

Forshaw and Mason (1954), by allowing three days to elapse after liver had been eaten before they examined the stools for occult blood, reduced the number of unexplained (false) positive results to 1% Since, however, elderly patients are commonly constipated, Forshaw and Mason's modification of the test does not materially improve the results in the older age-groups

No dietary restrictions were imposed on our patients Though an indefinite (but certainly small) number in

---

‡ Boxes of this powder were obtained from Messrs Allen & Hanburys Ltd., but, we understand, are no longer available

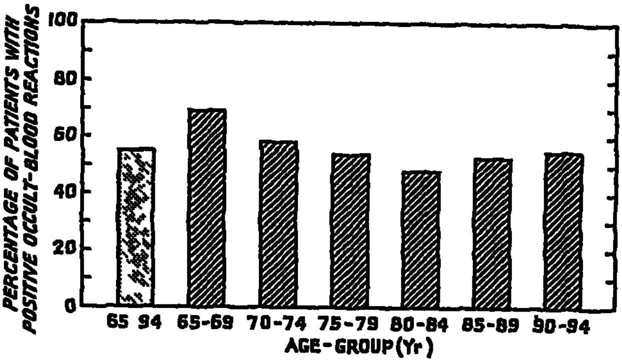

Fig 4—Age-distribution of positive occult-blood reactions.

both the anæmic and the non-anæmic groups may have given a false positive reaction for occult blood in the stools due to ingested liver, it is equally true for both groups (none had eaten black pudding, which is not a popular article of diet in and around Oxford) .Since the ingestion of liver in neither group of patients was in any way selective, and since there was no greater incidence of constipation in either group, the conclusion that the incidence of occult intestinal hæmorrhage was greater in the anæmic than the non-anæmic group to a highly significant degree is therefore valid, provided that the validity of Gregersen's test is accepted For the reasons given above, and for those that follow, we consider this to be the case, and we have therefore used the terms "positive reaction for occult blood" and "occult intestinal bleeding" synonymously

TABLE III—INCIDENCE OF OCCULT INTESTINAL BLEEDING IN ANÆMIC AND IN NON-ANÆMIC PATIENTS

—	No of patients investigated	No of patients with occult bleeding
Anæmic	64	50 (78%)
Non-anæmic	92	35 (38%)
Total	156	85 (55%)

Though we strongly affirm the validity of Gregersen's test (upon which our thesis largely rests) we are fully aware that many workers doubt its reliability, and it is therefore necessary to adduce further supporting evidence

At first sight the substantial number (38%) of patients in our non-anæmic group who gave positive reactions for occult blood in the stools appears to provide a contrary case We have admitted that an indefinite but certainly small number of these patients may have given a false positive occult-blood reaction due to ingested liver Long surveillance of these patients has, however, provided irrefutable supporting evidence because, although some died without or before becoming anæmic, most of them developed anæmia within two years, and only 4% remain in whom we have not yet been able to demonstrate an anæmic phase It must be emphasised also that our thesis is not that all who bleed from the gastrointestinal tract necessarily are or become anæmic—nor is this to be expected—but the contrary—i e, that the vast majority of anæmic patients admitted to this hospital show evidence of blood-loss from the gastrointestinal tract (that the blood-loss is an important factor in the pathogenesis of their anæmia is a logical corollary)

Although blood and fæces were examined simultaneously, anæmia and positive occult-blood tests did not necessarily coincide Indeed the positive occult-blood reactions often preceded the development of anæmia by some weeks, and in many cases there was no apparent time-relationship between them—and this too is not surprising Of paramount significance are the facts that almost all anæmic patients who lived long enough showed positive reactions sooner or later for occult blood in the stools, and that all patients with persistently positive Gregersen tests sooner or later, if they lived long enough, developed anæmia

All these reasons lead us to believe that Gregersen's test, when properly performed, is reliable, and that allegations to the contrary arise largely from neglecting the importance of fresh reagents, misinterpretation and lack of standardisation of results, and improper collection, storage, and preparation of fæcal specimens for the test Therefore we did not check our results by other methods, moreover all the established older tests are of very much more questionable validity, and those more recently introduced—e g, the o-tolidine and radioactive-isotope methods—have not yet been validated as regards diet, they are still being standardised against the Gregersen test and so would not have affected our results (Kohn and O'Kelly 1955, 1958, Ogilvie 1957) Nevertheless Gregersen's test will certainly be superseded—not because it is unreliable but because many unjustifiably believe it to be so, because it is undoubtedly cumbersome and tedious to perform, and because the carcinogenic potentiality of benzidine has given rise to so much alarm that benzidine has become virtually unobtainable and almost no pharmacist can be found who will handle it

The most promising of the newer methods is a slide technique using o-tolidine, but current experiments (P D Bedford and M M Weeks, in preparation) are showing that a tablet test using o-tolidine and fæcal suspensions is both convenient and simple in operation and promises to yield results as reliable as those obtained by Gregersen's method

Discussion

In the present series 41% of patients aged 65 or more admitted to hospital were anæmic at a hæmoglobin level of less than 80%, and 13% had a level of less than 70% Monroe's (1951) figures relate to 7926 unselected hospital patients aged more than 60 with "secondary anæmia" due to blood-loss and inadequate production (marrow hypoplasia) and are thus not strictly comparable, but the incidence of anæmia at a hæmoglobin level of less than 70% in Monroe's series is in substantial agreement with our own at the same hæmoglobin level—namely, 16% and 13% respectively

Hobson and Blackburn (1953), in their Sheffield survey, found the incidence of anæmia at a hæmoglobin level of less than 80% in old people living in their own homes to be much lower (5 1% of men and 6 5% of women, 6% of the total) compared with 41% in the present series The high incidence of iron deficiency (84%) in their anæmic cases is, however, in line with our finding of 94% Hobson and Blackburn state, referring in particular to Monroe's (1951) figures, " the idea that old people are anæmic may have arisen from hospital experience " The present series and the Sheffield survey are comparable as regards age and sex, and, though the conclusions of Hobson and Blackburn are undoubtedly substantially true, we feel that the discrepancy is not entirely explicable in terms of "hospital selection" of cases or of geographical differences, although either or both of these factors may be, and probably are, significant We feel that, if the hæmoglobin had been estimated more often in every patient in the Sheffield series, a much higher incidence of anæmia might have been revealed, because it is our experience that, over weeks or months, anæmia may be manifest only intermittently and can be discovered only by frequent serial estimations of hæmoglobin

The important studies on iron metabolism summarised by Moore (1955) show unequivocally that blood-loss is the principal factor in the pathogenesis of iron-deficiency anæmia

It has been shown with little room for doubt that dietary (nutritional) and intestinal-absorption defects do not by themselves—i.e, without blood-loss—play a major part in the production of iron-deficiency anæmia, and that, even when iron is completely absent from the diet, it would require many years for anæmia to develop, provided there was no concomitant blood-loss It has been shown too that achlorhydria, which increases in frequency with age (Bloomfield and Polland 1933), is not a significant factor (Moore 1955) Blood-loss, however, which is often intermittent and difficult to detect, is of primary importance, and, when there is such blood-loss, nutritional factors play a contributory part in the pathogenesis of iron-deficiency anæmia In these circumstances the role of ascorbic acid, which promotes the absorption of iron from the intestine in healthy people and even more in those who are iron-deficient (Moore 1955, *Lancet* 1955), is particularly significant The ascorbic-acid content of the diet of many elderly people is often deficient (Pyke et al 1947), especially in those who live alone, and this deficiency, together with a low dietary intake of iron, is without doubt of considerable contributory, but subsidiary, importance to the factor of blood-loss in the anæmia of old age

Another and common contributory factor which we feel has been insufficiently taken into account is the poor dietary intake of protein of many elderly people (Ohlsen et al 1948, 1950, 1952), which, together with the protein lost in the hæmoglobin by repeated hæmorrhage (Robscheit-Robbins and Whipple 1949, Whipple and Robscheit-Robbins 1951), may lead to iron-deficiency anæmia in elderly people through protein depletion Support would be lent to this theory both by our own frequent demonstration of hypoproteinæmia in elderly people admitted to hospital (P D Bedford, unpublished observations) and (admittedly by analogy) by Woodruff's (1955) observation in African natives, of anæmia which was associated with hypoproteinæmia and was corrected by increasing the dietary intake of protein alone

Neither hypoplasia of erythropoietic tissues nor primary deficiencies in intestinal absorption of iron (including the steatorrhœas, which are rare in elderly people) are considered here, because they are not germane to this discussion

Conclusions

Our conclusions about iron-deficiency anæmia in elderly people are in complete accord with those of Moore (1955), who states

> “ although theoretically poor diets or absorptive defects may cause iron-deficiency over many years on a nutritional basis it is far more likely that the cause is undetected loss (of blood) This loss may be slight or intermittent and may have to be diligently searched for It may take weeks or months until one can eventually demonstrate (that) occult hæmorrhage (is taking place) ”

The causes of occult intestinal blood-loss are, of course, many and various (ranging from peptic ulcer to uræmia), but it is not our purpose here to discuss the role of each in the pathogenesis of anæmia in elderly people or to assess the contributory role of such factors as hypoplasia of the bone-marrow

It is firmly our view that anæmia is common in elderly people, and that the concept of a physiological anæmia of old age is entirely erroneous It follows axiomatically that, in all such cases, full and detailed inquiry should be made into the cause of the anæmia and particularly into the source of any blood-loss §

Summary

Of 175 patients consecutively admitted to the geriatric unit, Cowley Road Hospital, Oxford, 156 aged 65 or more with no overt hæmorrhage were studied

Of these 156 otherwise unselected patients 64 (41%) were anæmic, with hæmoglobin levels of less than 80% (11 7 g per 100 ml), the anæmia in the large majority of cases being of the iron-deficiency type

Evidence of occult intestinal hæmorrhage was more than twice as common in the anæmic patients than in the non-anæmic, this difference is statistically highly significant and indicates a direct causal relationship between anæmia and occult intestinal hæmorrhage in the patients studied

It is concluded that anæmia is common in the elderly, and that, whatever other factors may be concerned, occult intestinal bleeding plays an important part in the pathogenesis of anæmia in old people

MEMBER, STATISTICAL RESEARCH UNIT, MEDICAL RESEARCH COUNCIL

From the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine, W C 1

COMMENDING the detailed recording of the evolution of chronic disease, Sir William Gull said “ In disease, one stream of morbid action naturally falls into another, and, whilst morbid anatomy gives us the final synthesis of results, there is but one possible means of analysis, and that by noting beginnings, order and progress ”

In the study of the natural history of chronic disease, the retrospective history of the already disabled patient is subject to the vagaries of human memory The sickness-absence records of a stable occupational group, on the other hand, have the merit of accuracy in timing the onset, duration, and sequence of disability from both major and minor illness arising during the working life, and, to some extent, this compensates for the poverty of clinical detail This paper describes how such records may supplement ordinary clinical studies by relating the frequency, timing, and character of respiratory and other illnesses among men doing the same job but in different environments to the development of chronic bronchitis

---

§ Our self-imposed axiom was of course applied, but we have deliberately omitted all ætiological data and discussion to avoid the possibility of deflecting attention from our single thesis However, it can be briefly stated here that 64% of the anæmic patients had organic lesions and in the remaining 36% no cause was found

Material and Method

The Treasury Medical Service advises the Post Office and other Government Departments on the health of their employees, and gives reasonably uniform advice on the clinical aspects of retirement on grounds of ill health throughout the United Kingdom At the time of such invaliding, the man's record of sickness absence during his Civil Service career is carefully reviewed In this study we have used the records of 565 postmen retired prematurely because of chronic bronchitis, and of 45 postmen who died in the service from that cause, during the period 1950–54 inclusive The subsequent fate of 517 of the invalided men who were entitled to pensions was investigated early in 1957 by the Post Office department concerned The 517 pensioners were followed up in this way for periods of up to seven years varying with the date of retirement, and of these men only 17 (3%) could not be traced The certified cause of death was obtained either from official records or at the General Register Office for 90% of the 124 who died during the follow-up period

The interpretation of the sickness pattern in men ultimately disabled or dead from bronchitis requires comparison with men not thus affected " Controls " were therefore randomly selected from among postmen who were still actively employed in the same office at the time of the " bronchitic's " death or retirement and who matched him as closely as practicable in age and length of service The Post Office furnished complete sickness-absence records both for the " bronchitics " and for these corresponding " control " individuals

Analysis of the data entailed a comparison of the sickness history at different ages of " bronchitics " and " controls " and a study of the coincidence of this disease with others, whether respiratory or not, in the same individual A recent survey (Fairbairn and Reid 1958) has shown that, of the more readily measurable aspects of the local environment, fog frequency is specifically related to the incidence of disablement and death from severe bronchitis For that reason we have compared the nature, progress, and prognosis of bronchitis among postmen working in areas where contrasts in fogginess imply different exposure to polluted air

Results

In table I are compared the incidence and duration of attacks of bronchitis at different ages in bronchitic postmen and their fit colleagues At all ages the men who were ultimately disabled or who died in the service had more and longer absences from bronchitis, and the excess increases absolutely and relatively after the age of 45 The average age at the first recorded attack of bronchitis is 44, and complete disablement or death in service ensued at the mean ages of 54 and 56 respectively

As table I implies, the study of the natural history of a chronic disease such as bronchitis requires long-term records The analysis has therefore been concentrated on 448 postmen for whom adequate controls were available, and for whom sickness records could be found covering service before the age of 45 and whose survival status at the end of follow-up was known 146 such postmen (33%) died either in service or in the follow-up period

TABLE I—INCIDENCE AND DURATION OF ATTACKS OF BRONCHITIS AMONG " BRONCHITICS " AND " CONTROLS "

Age (yr)	Attacks of bronchitis per 1000 man-years		Average duration of attacks (*days*)	
	Bronchitics	Controls	Bronchitics	Controls
15–	122	13	12 8	2 8
25–	145	54	12 7	7 3
35–	254	64	17 1	11 2
45–	736	101	23 0	14 9
55–59	1275	129	40 6	18 7

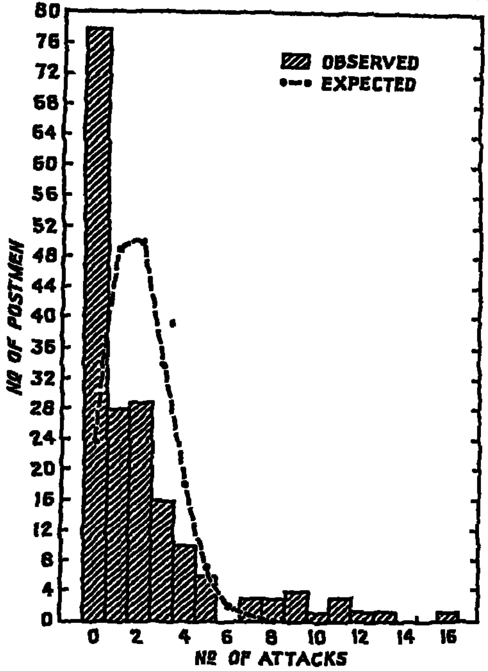

Fig 1—Distribution of no of attacks of bronchitis per person in "bronchitic" postmen aged 35–44, compared with expectation based on equal susceptibility

INDIVIDUAL PREDISPOSITION TO RESPIRATORY DISEASE

The excess in bronchitis morbidity in earlier life raises the question of individual susceptibility This can be further studied by setting out, as in fig 1, the distribution of the number of attacks per person among those bronchitic postmen whose records were available for the whole of their service between the ages of 35 and 44 inclusive This observed distribution can be compared with expectation based on the Poisson law of chance behaviour, which assumes similar exposure and equal susceptibility for every individual There is a clear suggestion that not all the bronchitics were equally susceptible, and that, in fact, the overall excess in frequency over the " control " level seen in fig 1 may come partly from the adverse experience of a " bronchitis-prone " minority As table II shows, this minority of men with a more than average number of attacks of bronchitis early in middle life have nine times as many recorded attacks of asthma—an excess which emphasises the allergic component of their sickness history But they also have more absences from other respiratory infections and from other causes of absence There is thus some general tendency to incur absence from work, but the seriousness of their disability is obvious in the fact that 20% of these men are known to have died either in the service or within seven years of retirement

TABLE II—INCIDENCE OF RESPIRATORY AND OTHER DISORDERS IN " BRONCHITICS " WITH DIFFERING BRONCHITIC HISTORIES UNDER THE AGE OF 45 (ATTACKS PER 1000 MAN-YEARS UNDER 45)

Disorder	No of attacks of bronchitis under age 45	
	More than average	Less than average
Upper respiratory illness	624	457
Asthma	56	6
Pneumonia	7	4
Pleurisy	10	7
All other illness	1134	822

ASSOCIATED RESPIRATORY AND CIRCULATORY DISEASE

The disparity in sickness experience between "bronchitics" and "controls", in table I, is greatest after the age of 45. Table III shows the contrast in attack-rates after that age between postmen who had been retired because of bronchitis and were alive at last follow-up, those who had died, and the matched controls for each group. Attacks of bronchitis and of asthma are 8–10 times more frequent in both groups of bronchitics than in presumably healthy men of the same age working in the same conditions. There is also a significant excess over the control level in both groups in the frequency of upper-respiratory infections. Circulatory disorders, usually described as "myocarditis" or "hypertension" by the certifying physicians, are likewise much more frequent in both bronchitis groups. The particularly high incidence among those who died prematurely indicates the prognostic importance of such diagnostic labels. Pneumonia and pleurisy are much commoner, as table III shows, among the bronchitics than among the controls, but the difference between "dead" and "survivors" at follow-up is small. Indeed, sickness histories of the dead appear to be distinguished more by the frequency of cardiovascular disorders than of other diseases of the chest.

TABLE III—FREQUENCY OF BRONCHITIS AND RELATED DISEASE AMONG "BRONCHITICS" AND "CONTROLS" (ATTACKS PER 1000 MAN-YEARS OF EXPOSURE OVER 45)

Diagnosis	Bronchitic survivors	Controls	Bronchitic deaths	Controls
Bronchitis	914	115	815	82
Upper respiratory	539	321	471	359
Asthma	56	6	56	5
All heart disorder, including hypertension	28	5	54	2
Pneumonia	10	2	14	2
Pleurisy	17	6	17	3

TABLE IV—PNEUMONIA AND/OR PLEURISY PRECEDING THE FIRST ATTACK OF BRONCHITIS IN "BRONCHITICS" ACCORDING TO STATUS AT FOLLOW-UP

Population	Status at follow-up			Case-fatality rate (%)
	Survival	Death	Total	
No. of "bronchitics"	302	146	448	—
No. of cases where				
Pneumonia preceded bronchitis	8	4	12	33
Pleurisy preceded bronchitis	15	9	24	38
Pneumonia or pleurisy preceded bronchitis	20	12	32	38

Rather surprisingly, pneumonia and pleurisy appear in table IV to precede repeated attacks of bronchitis fairly seldom—in only 32 out of 448 cases (7·1%) was either condition the first major respiratory illness recorded. The ultimate fatality-rate in these 32 cases is at 38% little different from 32% in the remaining cases.

The experience after the age of 45 of the two groups of bronchitics in respect of other disease categories is set out in table V. Clearly, although those whose death is recorded in the service or at follow-up differ little from their controls, the invalids who survive have consistently more absences than the corresponding controls. This disparity in absence from other diseases, which is much less than that noted for bronchitis, no doubt reflects the psychological factors affecting a minority of the less seriously ill men.

OTHER ASSOCIATED DISEASES

Table VI shows the experience of peptic ulceration in "bronchitics" and "controls" compared with expectations based on the age-specific incidence-rates derived from a field survey of peptic ulceration in other occupational groups in Britain (Medical Research Council 1951). For the "controls", the observed number of cases is just within the chance limits of the expected value, among the "bronchitics" twice as many men had peptic ulcer as expected—a significant excess.

TABLE V—FREQUENCY OF NON-RESPIRATORY ILLNESSES AMONG "BRONCHITICS" AND "CONTROLS"

Diagnosis	"Bronchitic survivors"	"Controls"	"Bronchitic deaths"	"Controls"
Rheumatic	216	122	123	122
Gastrointestinal	102	75	77	56
Skin	63	37	37	54
All other	915	556	731	639

The incidence of other serious diseases can be further studied in the distribution of the cause of death given by the attending practitioner for the 113 deaths among the 500 pensioners successfully followed up after discharge. To the total man-years of exposure throughout the period of follow-up for the 500 men were applied the death-rates in England and Wales by cause for males aged 50–59 in 1952, the middle year of the period. The results of comparing observation with expectation on this basis are given in table VII. Deaths from bronchitis and other respiratory causes are, of course, grossly excessive, but the number of deaths from non-pulmonary cancer (6) agrees quite closely with the number expected at national death-rates (4). Even with 10% of all deaths unallocated, lung-cancer deaths observed (12), on the other hand, are significantly more than might have been expected at these standard rates (3). Similarly, deaths certified as due to coronary disease are significantly more than the expected numbers.

TABLE VI—NUMBERS OF MEN WITH RECORDED HISTORY OF PEPTIC ULCERATION IN "BRONCHITICS" AND "CONTROLS" (COMPARED WITH THAT EXPECTED AT AGE-SPECIFIC INCIDENCE-RATES DERIVED FROM A MEDICAL RESEARCH COUNCIL SURVEY)

—	"Bronchitics"	"Controls"
Recorded	60	46
Expected	30	36

ATMOSPHERIC CONDITIONS AND ONSET OF BRONCHITIC ATTACKS

The short-term variation in the health of chronic bronchitics implies a sensitivity to atmospheric changes. There is some disagreement, however, about the relative effects of cold and humidity, particularly during fog, and of the chemical pollutants which inevitably pervade the urban fog.

TABLE VII—CERTIFIED CAUSE OF DEATH AT FOLLOW-UP IN POSTMEN INVALIDED FROM BRONCHITIS, COMPARED WITH THAT EXPECTED AT GENERAL MALE DEATH-RATES FOR 1953 AT AGES 50–59

Cause of death	No. of deaths	
	Observed	Expected
Bronchitis	51	2
Other respiratory	11	1
Cardiovascular		
Coronary disease	13	5
Other	10	3
Cancer		
Lung and respiratory	12	3
Other sites	6	4
Pulmonary tuberculosis	1	1
Central nervous system	6	2
Digestive	2	1
Other	1	3

In the 1939–45 war, records of fog frequency in the London area were regularly maintained Among the bronchitic postmen included in the survey, 103 worked in that area during the period 1941–46 It was thus possible to compare monthly trends in the incidence of absence from work due to bronchitis with contemporary levels in temperature, humidity, and presumptive air pollution during fogs which decreased visibility to below the arbitrary standard range of 1100 yards The relation of the environmental factors to the frequency of onset of bronchitis attacks can be most readily summarised by averaging the values in each month of the year over the six-year period Fig 2 shows the results of this condensation of the data on a logarithmic grid which clarifies the relative changes in the variables from month to month

Temperature (here displayed in inverse form as 1/°F), fog, and bronchitis frequency are clearly all related, but, although the incidence of bronchitis rises with the autumnal fall in temperature, the subsequent month-to-month changes in incidence are more closely related to changing fog frequency and thus, in a built-up area such as London, to the associated air pollution

PROLONGED EXPOSURE TO AIR POLLUTION AND EVOLUTION OF CHRONIC BRONCHITIS

The immediate effects of exposure to peak concentrations of air pollutants may thus be obvious, but the long-term results are still obscure The natural history of bronchitis can be usefully compared in *four groupings* of areas in the United Kingdom, with nearly equal postmen populations, arranged in order of the frequency there of fairly dense and presumably polluted fog Table VIII shows the trends in attack-rates among bronchitic postmen in these four areas at different ages At the youngest ages there is little difference between the areas, but over the age of 45 the disparity between lightly polluted and heavily polluted areas becomes obvious

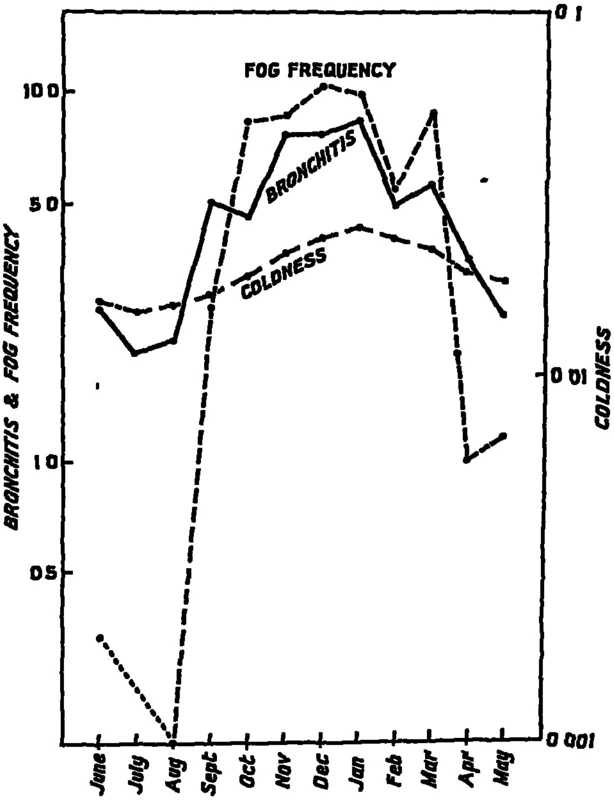

Fig 2—Local environment and onset of bronchitis in "bronchitic" London postmen (average of mean monthly values 1941–46 shown on logarithmic scale)

Bronchitis=attacks per 100 man-months
Coldness=reciprocal of mean monthly temperature (°F)
Fog frequency=average number of days per month with visibility less than 1100 yards
No foggy days occurred in July in 1941–46

TABLE VIII—AGE-TRENDS IN SICKNESS ABSENCE FROM BRONCHITIS IN "BRONCHITIC" POSTMEN IN FOUR GROUPS OF AREAS WITH INCREASING PRESUMPTIVE AIR POLLUTION (ATTACK-RATE PER 1000 MAN YEARS)

Age (yr)	Pollution group			
	I	II	III	IV
25–	184	120	143	119
35–	243	200	298	251
45–	568	579	748	967
55–59	1069	1126	1259	1563

The end-result of local conditions may be more apparent in the mortality of "bronchitic" postmen either while still in the service or after invaliding Table IX shows the proportion of all "bronchitic" postmen who die from the disease or its complications while still in the service. This goes up from 3% in the least foggy to 11% in the most foggy areas of the country

TABLE IX—DEATHS IN THE SERVICE, AND TOTAL DEATHS AND RETIREMENTS FROM BRONCHITIS IN POSTMEN, IN FOUR GROUPS OF AREAS WITH INCREASING PRESUMPTIVE AIR POLLUTION

Pollution group	Deaths in service	All deaths and retirements	Rate (%)
I	4	126	3
II	8	138	6
III	16	195	8
IV	17	151	11

Among those who are retired on pension, the proportions surviving at each year thereafter in the less heavily and more heavily polluted areas can be seen in the life-table statement of survivorship given in table X At the end of the seventh year of follow-up, 36% of the original group in the less affected regions are likely to have died, but 44% will have died in the more foggy areas The seriousness of the disease and the aggravating effect of atmospheric conditions are thus obvious The nature of this aggravation is apparent in table XI, which shows the greater incidence of pneumonia, pleurisy, and heart disorder in the more fog-ridden parts of the country in the critical age-group of 45–54 The high wastage from bronchitis in this age-group in both areas leaves male residual populations of bronchitics who differ little in the frequency of complications

TABLE X—PROGNOSIS IN POSTMEN INVALIDED OWING TO CHRONIC BRONCHITIS EXPECTED NUMBERS OF SURVIVORS UP TO SEVEN YEARS FROM THE TIME OF INVALIDING IN THE MORE POLLUTED AND LESS POLLUTED AREAS OF THE UNITED KINGDOM

Years after invaliding	Pollution groups	
	I and II	III and IV
0	1000	1000
1	946	911
2	871	868
3	823	797
4	779	763
5	742	687
6	723	613
7th yr	641	555

Discussion

In the study of the natural history of a chronic disease we are looking for evidence of personal and environmental factors which favour its onset or evolution and for illnesses which aggravate its course or point to a common origin

The effect of epidemics of upper-respiratory infection on bronchitis mortality has already been suggested by the similar fluctuations in total sickness absence, which are largely due to its respiratory component, and the annual death-rates from bronchitis (Reid 1956) At all ages postmen who are ultimately disabled or die because of bronchitis do have far more frequent absences from upper-respiratory infections, asthma, pleurisy, and pneumonia than their fitter colleagues working in the same conditions On the other hand, pneumonia and pleurisy are relatively seldom the precursors of a series of repeated attacks of bronchitis, and cases beginning in this way have much the same prognosis as the others The finding that sickness histories of those who died within the period of review were distinguished more by excessive frequency of circulatory disorder than by a high incidence of pleurisy and pneumonia is more consistent with Fulton's (1953) emphasis on the frequency of such complications than with views such as those of Parkinson and Hoyle (1937) that congestive heart-failure was seldom the result of chronic lung disease

TABLE XI—INCIDENCE OF CARDIOVASCULAR AND PULMONARY COMPLICATIONS IN BRONCHITIC INVALIDS IN AREAS OF DIFFERING POLLUTION (ATTACK-RATES PER 1000 MAN-YEARS)

Age (yr)	Group I and II	Group III and IV
All heart and hypertension		
25-	4	0
35-	4	3
45-	14	29
55-59	89	80
Pleurisy and pneumonia		
25-	16	18
35-	12	14
45-	21	27
55-59	48	45
Total		
25-	20	18
35-	16	17
45-	36	56
55-59	137	125

These disagreements between physicians practising in different parts of the country may be explained by the evidence from this study of the effect of regional differences in air pollution on respiratory morbidity The importance of environment to disease evolution is clearly implied by the contrasting sickness and mortality experience of bronchitic postmen in parts of the country with different levels of presumptive air pollution Not only are postmen more frequently disabled by, or die from, bronchitis in the more heavily polluted areas (Fairbairn and Reid 1958), but there is some indication that the character of the illness differs It seems that after the age of 45 the severity of these respiratory illnesses is increased by the atmospheric conditions, while grave chest infections and circulatory embarrassment cause large increases in both the immediate and long-term fatality-rates The acute effects of foggy conditions emerge from the coincidence of onset of bronchitic attacks with thick fog rather than of cold and humidity—a finding from sickness records which corresponds to the more detailed clinical records of the association produced by Waller and Lawther (1957)

Although the role of atmospheric pollution in precipitating and aggravating bronchitis may thus be evident, the personal factors involved are still obscure An undue susceptibility to absence before the age of 45 because of respiratory disease seems to be characteristic of a minority of the bronchitic postmen surveyed, but the total excess in bronchitic incidence over the control level was only partly explained by the adverse experience of this group These men have also more absences from other causes than the corresponding " controls ", but the excess is only a quarter as great as for bronchitis and asthma, and 20% of these men died either in the service or within the period of follow-up Thus although psychological factors can obscure its pattern, the sickness record in earlier adult life may have some value in identifying men more likely to develop disabling respiratory disease

Berkson (1946) has pointed out the fallacy inherent in the use of hospital admission records to identify significant associations of two or more diseases reported in the same individual Quite apart from any medical considerations about the severity of complicated disease, an individual with two serious conditions is statistically more likely to be admitted to hospital than a patient with only one To some extent the same argument applies to premature retirement on health grounds, but comparison of the frequency of diseases other than bronchitis among the " controls " drawn at random from the same population should minimise the risk of overestimating the significance of any associations found In the circumstances, the finding of an excessive incidence compared with the standard rate of peptic ulcer and of death from cancer of the lung and coronary disease does suggest that smoking may be a factor common to the development of conditions which have all been shown to be associated with cigarette consumption (Doll and Hill 1956, Hammond and Horn 1957) Browne and Vineberg (1932) pointed out that hyperchlorhydria may result from the high arterial carbon-dioxide level in emphysema, but the abnormal coincidence of peptic ulcer and chronic bronchitis is as likely to be due to the aggravation of both diseases by smoking Because of the real possibility of diagnostic confusion between the later stages of disease of the respiratory and circulatory systems, however, this evidence can be regarded as indicative rather than absolute Again, since no smoking histories of either " bronchitics " or controls could be obtained, the role of smoking as a contributory cause of regional and other differences in the natural history of bronchitis cannot be assessed

Summary and Conclusions

In this study of the evolution of chronic bronchitis disease in a homogeneous occupational group widely dispersed over the country, the sickness-absence records for the whole of their service of postmen who were permanently disabled by chronic bronchitis, or who died from this cause, while still in the service are compared with those of other postmen of the same age still actively employed in the same area and with comparable length of service The incidence of all forms of respiratory disease at all ages from 20 to 59 is contrasted in the two groups

The pattern of disease, including the incidence of serious pneumonia, pleurisy, and circulatory disturbances, was also compared in groups of bronchitic postmen who had worked in four divisions of the country graded according to presumptive air pollution based on fog frequency The time-relations of onset of attack of bronchitis and contemporary fog and climate were studied in the histories of bronchitic postmen working in the London area

Those men who were given pensions on retirement on health grounds were followed until death or up to seven years after the date of invaliding Their mortality experience by cause was then compared with expectations based on national age-sex specific death rates Comparisons were also made between survival rates in the more and less heavily polluted parts of the country

From the analysis of these data, several significant findings emerged

(1) Postmen who were ultimately disabled or who died prematurely from chronic bronchitis had more and longer absences than their controls even in early adult life This excess was partly due to the presence among them of a minority prone to absence because of asthma and from all causes, including respiratory disease

(2) After the age of 45 the "bronchitics" became rapidly worse with 8–10 times as many attacks of pneumonia, pleurisy, and asthma as their "controls" Circulatory disorders were particularly excessive among bronchitics who died either while still in the service or within seven years after invaliding

(3) Bronchitic invalids had more disability from peptic ulcer and more deaths from coronary disease and lung cancer than the population at large

(4) Bronchitic postmen who had worked in the more fog-ridden parts of the United Kingdom had, after the age of 45, far more frequent absences from bronchitis, pleurisy, and pneumonia and circulatory disorders than bronchitic postmen from less polluted areas The onset of bronchitic attacks was more closely related to fog frequency than to cold or humidity, and there were clear gradients between the less and more polluted areas in the short-term and long-term prognosis of the disease

These findings lead to the conclusion that there are important differences, probably due to variations in local air-pollution levels, in the character as well as in the frequency of bronchitic disease in different parts of the country Although the coincidence in bronchitics of diseases such as peptic ulcer, coronary disease, and cancer of the lung is consistent with a common origin in smoking, no data on smoking habits were available to confirm or deny its role in the natural history of chronic bronchitis

We are most grateful to Dr W E Chiesman, and Dr M C W Long and their colleagues of the Treasury Medical Service for their help, and to the Post Office authorities for providing copies of the sickness-absence records, for tracing the invalided postmen, and for permission to use the data Both the Post Office authorities and the Registrar General gave much help in ascertaining the cause of death in the follow-up study Miss Linda Colwell did the computing and Mrs Sheila King drew the diagrams

DIETARY TREATMENT OF MYOPIA IN CHILDREN

P A Gardiner
M B Lond, D O M S
RESEARCH FELLOW IN OPHTHALMOLOGY, GUY'S HOSPITAL, LONDON, S E 1

Myopic children in general grow more irregularly and mature earlier than their fellows (Gardiner 1954) The rate of visual deterioration coincides, in both time and degree, with spurts of physical growth (Gardiner 1954, 1955)

Increase in myopia is greater and commoner in children who refuse animal protein in their diet than in those whose tastes are more catholic (Gardiner 1956a) A nutritional problem has been exposed, in that myopic children whose eyes are deteriorating eat less food for every pound they increase in weight than do normally sighted children and those myopes whose eyes are not deteriorating The food element most noticeably implicated is animal protein (Gardiner 1956b)

The present investigation, of which this is a preliminary report, was based on the possibility that rectification of the apparent imbalance of growth and nutrition might diminish the deterioration in eyesight which is seen in most myopic children

Material

The eyesight of two groups of schoolchildren was examined and compared Children known to have congenital myopia were excluded

The control group consisted of the myopic children seen during a period of about six months, at an ordinary school clinic

Most of the treated group were children whose parents elected not to have them seen at the school clinic but preferred or were advised to make their own arrangements (These children were originally seen either at hospital or under the scheme provided by the supplementary ophthalmic service) A proportion, however, came from school clinics other than the ones contributing the control group No other selection was made and there were no refusals to attend The two groups appeared comparable in health, in social class, and in the nature of their myopia, though precise data on these points cannot be adduced Known congenital myopes were excluded from both groups The average height and weight in each group is shown in table I there is no consistent bias

The alternative method—of treating a random selection of schoolchildren—was discarded owing to the difficulty of preventing the spread of information between those being treated and those not, either in the waiting-room, or, as would often have been the case, between children in the same family, one of whom was being treated and the other *not* Dummy treatment in this investigation would have been impossible

Refraction was done in all the children *in* both groups at the outset, six months later, and a year later

Method of Treatment

Each child's diet, as taken at home and at school before treatment began, was assessed using standard tables of food composition (McCance and Widdowson 1946) The same dietitian examined all the children A diet was then devised to enable the child to take 10% of his calorie intake as animal protein, the calories being based on the child's natural appetite No attempt was made to alter the calorie intake Free use was made of 'Casilan' (calcium caseinate) as a supplement for children with an obvious antipathy to animal protein

TABLE I—INITIAL HEIGHTS AND WEIGHTS OF CHILDREN, ACCORDING TO DEGREE OF INITIAL MYOPIA IN DIOPTRES (D)

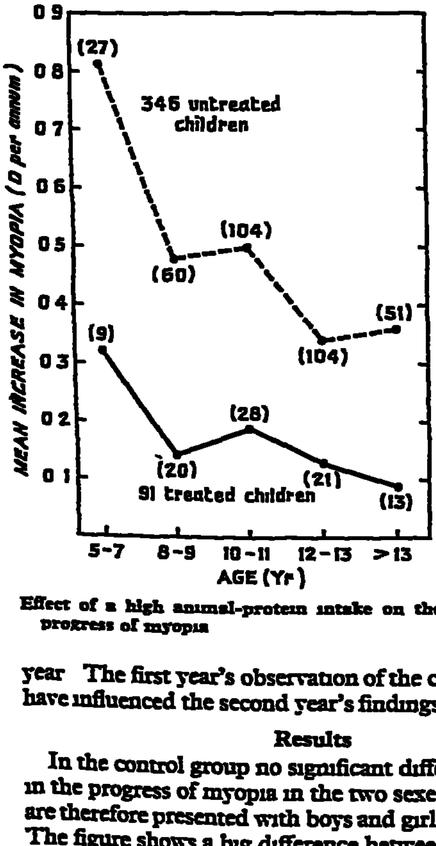
Degree of myopia (D)	Height (in.)		Weight (lb)	
	Control	Treated	Control	Treated
−0·25 to −0 9	55·5	55 3	78 3	76 9
−1·0 to −1·9	55·5	56 4	76 1	78 5
−2·0 or more	55·5	55·9	78·4	79 8

The control group of children was given no dietary advice whatever

Throughout the year's treatment a close watch was kept on deviations from instructions Each child was seen two or three times in the year and the diet adjusted to try to keep the balance at the optimum level

The change in refraction in the treated group during the year was compared with the change in the control group Some of the controls were under observation for two years It was thought justifiable to use these two annual rates of change in the control group as separate observations

In the treated group, it was thought unjustifiable to include the second year's changes in those few whose treatment lasted two years, since the first year's treatment could in theory have influenced the refractive changes in the second year The first year's observation of the controls could not have influenced the second year's findings on refraction.



Effect of a high animal-protein intake on the progress of myopia

Results

In the control group no significant difference was found in the progress of myopia in the two sexes, and the figures are therefore presented with boys and girls added together The figure shows a big difference between the treated and untreated groups, at all ages, in the rate at which the myopia deteriorated In the younger children the deterioration was greater in the controls by 0 5 dioptre (D) per annum (mean figure) In the older children the process was all but arrested in the treated group Table II shows how the eyes of the treated group fared compared with the controls The ratio C/T (control/treated) shows that the more severe the myopia at the start of treatment, the bigger the difference between the treated and untreated groups But this difference bore no consistent relation to age

TABLE II—AVERAGE ANNUAL INCREASE IN MYOPIA

Myopia at start (D)	−0 25 to −0·9		−1 to −1·9		−2·0 or more	
—	No of children	Change (D)	No of children	Change (D)	No of children	Change (D)
Controls	139	−0 39	98	−0·51	109	−0·60
Treated	20	−0 17	26	−0·20	45	−0 18
C/T	2 30		2 55		3 33	

Age (yr)	*Ratio C/T*
5–7	2·53
8–9	3 43
10–11	2·63
12–13	2 62
13–	4 11

In table III the figures have been broken down into subgroups according to age and degree of myopia at the beginning of treatment or observation

Tables II and III show that the treated children deteriorated more slowly than the untreated in every group except at the age of 13 or more in those with the least severe myopia

TABLE III—AVERAGE INCREASE IN MYOPIA IN TREATED AND CONTROL PATIENTS ACCORDING TO AGE

Age (yr)	Initial myopia (D)	−0 25 to −0·9		−1·0 to −1 9		−2·0 or more	
	—	No of children	Annual change (D)	No of children	Annual change (D)	No. of children	Annual change (D)
5–7	Control	10	−0·6	8	−0 72	9	−1 12
	Treated	5	−0 32	1	−0·60	3	−0 23
8–9	Control	24	−0·44	18	−0·54	18	−0 53
	Treated	3	−0·0	6	−0·05	11	−0 22
10–11	Control	46	−0·45	26	−0·58	32	−0·51
	Treated	5	−0·22	11	−0 19	12	−0 17
12–13	Control	40	−0·25	36	−0·40	28	−0·40
	Treated	5	−0·04	2	−0·15	14	−0·16
>13	Control	19	−0·23	10	−0·33	22	−0·46
	Treated	2	−0 25	6	−0·02	5	−0 10

The biggest increase in an individual child was 2 3 D in a year in the untreated group and 1 6 D in the treated group In general the treated group deteriorated at about a third the rate of the untreated (see figure)

Table III also reveals that the distribution of myopia differed in the two groups, there were relatively more severe cases in the treated than in the control group Moreover, in the control group, the more severe the myopia at the beginning of the period of observation, the more it progressed. This is an interesting observation on its own account, and is not shown in the treated group

TABLE IV—RELATION OF THE AMOUNT OF ANIMAL PROTEIN CONSUMED IN THE TREATED GROUP TO THE MEAN CHANGE IN MYOPIA (D)

% of calories taken as animal protein	Initial degree of myopia (D)	0·25–1·9		>1·9		Average of means
	Age (yr)	<12	>12	<12	>12	
<8 1		−0 24	−0·23	−0·11	−0·33	−0 23
8 1–8·9		−0 20	−0·22	−0·26	−0·35	−0·26
>8·9		−0 15	−0 20	−0·28	−0·03	−0·06

+ = improvement.

The object of the treatment was to try to give 10% of the calories as animal protein. At the end of the period an assessment was made of the actual proportion taken in this form It proved possible to divide the children into those who took up to 8 0% of their calories as animal protein, those who took 8 0–8 9%, and those who took more than 8 9%

The changes in refraction in these subgroups are shown in table IV

In three of these four subgroups, those who took the most protein deteriorated least, and the average shows

TABLE V—RELATION OF THE AMOUNT OF ANIMAL PROTEIN CONSUMED IN THE TREATED GROUP TO THE MEAN DETERIORATION IN MYOPIA (D)

% of calories taken as animal	Age (yr.)	<12				>12			
	Initial myopia (D)	−0·25 to 1·9		−2·0 or more		−0·25 to −1·9		−2·0 or more	
	—	No of children	Change	No of children	Change	No of children	Change	No of children	Change
<9·0	Boys	7	−0·37	6	−0·17	8	−0·24	3	−0·37
>8·9		8	−0·06	2	−0·40	3	+0·23	4	+0·18
<9·0	Girls	9	−0·08	6	−0·25	4	−0·12	5	−0·32
>8·9		5	−0·28	8	−0·25	1	+0·10	5	−0·17

+ = improvement.

clearly that there is a big difference in the change in myopia between those children with the highest protein intake and the others. Those over 12 years of age have done better than those under 12. But the figures in table IV are not significant statistically—even if those over 12 years of age only are considered (P=0·07).

If the sexes are separated the results shown in table V are obtained.

Excluding the girls under 12 in table V, P=0·02. Therefore it is very unlikely that the differences in the myopic process in this table between those who took the smaller and those who took the larger quantity of protein are due to chance. The figures for the subgroups in table V are not significant. These figures indicate that in five out of eight subgroups the higher intake of protein is associated with a much reduced rate of deterioration of myopia in the treated group of children. In three out of four subgroups of those over 12 the mean degree of myopia improved.

Discussion

The difficulties of controlling a clinical experiment such as this are numerous. Myopia develops in a haphazard way, and though the process is most active amongst younger children, which may possibly mean that it is most active at its inception, new cases are continually arising at all the growing-ages. Since children's eyes are examined relatively infrequently, it is very hard to establish, in a given case, precisely when myopia has begun. In this investigation, so far as is known, the estimate of refractive errors was made, in both groups, at a random moment in the progress of the myopia, and there should therefore be no difference between the two groups in the duration of the disease.

The validity of the results depends largely on the similarity of content of the treated and untreated groups.

Both consisted of children of all ages, but not all the treated children were taken out of the school clinics. Certainly the treated group contained a greater proportion of higher myopes. It is possible that some of their parents were more anxious about the welfare of their children's eyes than those at the school clinic, but I find it hard to believe that this would influence the outcome favourably. These children's eyes would not be likely to be worse than those of other children if their parents *could* by care and trouble improve them—especially if this improvement depended on general healthy environments. The contradiction is obvious.

There was, in my opinion, no discernible difference between the outlook and type of child and parent who happened to be directed to the treated group and the type of child and parent who attended the school clinic (untreated group).

The fact that in the control group progress was proportional to the severity of the myopia (table II) seems to militate against treatment being as successful in children with severe myopia, yet they are the ones that did best (table II) and were more common in the treated group.

It must be admitted that, by strict statistical standards, selection was not random, and therefore there may have been some unknown factor of selection or dissimilarity between the groups which influenced the outcome. This possibility seems remote and no sensible guess can be made about it.

The one consistent difference between the two groups is that the treated group consumed a high quantity of animal protein. If this contributed to the difference in the rate of deterioration between the two groups, it would be reasonable to suppose that those who consumed the most would have done the best. In the treated group this was found to be broadly true, though *under the age of 12 in the girls it could not be established.* None the less, over the rest of the field of inquiry the figures show a strong tendency towards an effect being obtained in the children taking over 9% of their total calories as animal protein.

A clue to the anomalous behaviour of the girls under 12 may be obtained by studying their growth. Their weight increased by 15·1% during the year's treatment, whereas the weight of the boys of the same age increased by only 11·7%. The height increase in the two groups was about the same, and their dietary intake also was similar. Previous studies in untreated children have shown that myopia is likely to increase faster in children with a high weight-height ratio (Gardiner 1954).

Secondly, the animal-protein intake per pound increase in weight is much lower in children with progressing myopia than in those with stationary myopia (Gardiner 1956b). The animal protein intake of these girls during the year's treatment was similar to that of the boys, but they increased in weight substantially faster than the boys.

It is hard to imagine how the group of treated children differed from the untreated in any way which would affect the issue, and even harder to conceive of a common reason for this and for the fact that those who carried out the treatment to its full tended to do best. The most likely reason for my findings is that the high animal protein intake was beneficial.

The supporting evidence is in favour of this probability. I have previously shown that, compared with normally sighted children, myopic children more often refuse animal protein (Gardiner 1956a). Moreover, hypermetropia in a growing animal can be reduced by limiting the protein content of the diet (Gardiner and Macdonald 1957).

As already mentioned, casilan was offered to children whose appetite or taste prevented them from taking their animal protein as ordinary food, and here again there was considerable variation in the children's acceptance of the treatment and in their response. In the 16 children who consumed the amount of casilan advised, the mean change in refraction was an improvement of 0·02 D, in the 42 who took some casilan, the mean change was a deterioration of 0·16 D, and in the 14 who refused to take any casilan the mean change was a deterioration of 0·22 D.

These figures relate to changes in six months, and represent an extension of the work already described. Many of these children were not included in the other results because a year's treatment had not been completed. The trend here is clear, and the deterioration of 0·22 D in six months in the worst group is comparable with that of the worst in the main treated group who deteriorated 0·32 D in a year. The deterioration in the casilan-treated group was in fact rather worse—as one would expect, since they were put on casilan because their protein intake, even on the diet, was too low.

Arising out of the main investigation various subsidiary results have been obtained. These show that milk plays an important part in the control of myopia and that some part is played by the vegetable protein intake These will be the subject of a further communication

All these findings need further elaboration, but they are strongly in favour of a dietary influence on the course of myopia in growing children and adolescents It is certainly possible that the balance of the diet, and not the animal-protein content, may be a factor, since it has been radically changed by the treatment. However, it is impossible to establish this without a rigid control of both carbohydrate and fat intake

The findings throw no light on the pathological processes involved in myopia, and some of the incongruities may be explained if myopia has more than one cause They have no direct bearing on possible causes of myopia, since all the children had established myopia when the investigation began

Until reliable figures for the incidence of myopia can be obtained in different places and at different times, and until a suitable experimental animal can readily be induced to become myopic, research into the causes of myopia will be halting

Discussion of Technique Involved

From the practical point of view it is extremely important to have an accurate assessment of the diet—both of the calories yielded and of its constituents This information can be obtained only by a trained expert It is useless, both for scientific and for clinical purposes, merely to ask general questions about the diet Experience shows that patients cannot answer questions about their food at all accurately unless the questions are asked in great detail, and even then there is room for individual interpretations of the replies given Probably no two dietitians would agree on the constitution of a patient's diet, but I have been fortunate in having the same dietitian through all these investigations Hence in this investigation it is possible to compare results in different patients and in one patient at different times These comparisons would not be so easily made with a team of dietitians and would be impossible without a dietitian at all

Some of the children have shown a tendency to put on weight, some have what seems to amount to an anorexia, some are extremely particular in their tastes, some are energetic, some lazy, most are growing irregularly, some are well to do, and some are "on welfare" All these factors have had to be taken into consideration, and diets and advice have to be adjusted in every case for the individual None the less it has been possible to reach a level of animal-protein intake of 9 0% of the calories in 43% of the children, and these have done better than the rest

Summary and Conclusions

In a group of shortsighted children who attended the research clinic at Guy's Hospital and received extra animal protein, the rate of visual deterioration was much less than in a group who attended the ordinary school ophthalmic clinic and whose diet was not changed

The difference in treatment between the two groups lay primarily in the increased amount of animal protein consumed by the treated group, though it is clear that other factors are at work

With a few exceptions among the younger children, those who carried out the treatment most assiduously tended to deteriorate more slowly than their more casual fellows Of the children over 12, there was actual improvement in most of those who took the greatest quantity of animal protein

Whatever may be the cause of acquired myopia in children and adolescents, its course can be beneficially modified by dietary means The factors involved still need elucidation

This work has been done partly with facilities from the Endowment Fund of Guy's Hospital, and in particular I am grateful to Mr Frank Law for his support I could not have produced the results without the cooperation of Dr K M Bodkin, area medical officer of health for Hendon (Middlesex County Council) and her staff of health organisers The dietetic work has been shouldered entirely by Mrs V Zivanovic, and my indebtedness to her is great Lastly I must mention the intensive secretarial work done by Mrs A. D Holland

EPIDEMIOLOGY OF ARTERIOSCLEROSIS IN ISRAEL

GERTRUDE KALLNER
M.D Berlin
CHIEF, HEALTH SECTION, CENTRAL BUREAU OF STATISTICS,
GOVERNMENT OF ISRAEL, JERUSALEM

THE study of geographical variations in pathology and of world-wide epidemiology are expected to give the answers to questions of ætiology where the purely clinical approach has so far failed Malignant neoplasms are being thus investigated, but in other diseases which possibly result from long-term environmental effects there is need to supplement clinical by global epidemiological research Foremost among these—with regard both to the urgency of the problem and to the variety of approaches used—is arteriosclerosis

In Israel the "ingathering of the exiles" has produced a population of the most varied geographical extraction, physical habitus, and cultural background, which can still be studied in distinctive groups

Here the computation of age-specific mortality-rates for groups of different geographical origin revealed unexpected differences in the localisation of arteriosclerosis

This study is based on deaths assigned to arteriosclerosis according to the Manual of International Classification of Diseases, Injuries and Causes of Death (World Health Organisation, 1948) Cerebral arteriosclerosis refers to nos 330 to 334, coronary-artery disease to nos 420,0 and 420/1 of this classification

It was found that, within each age-group, coronary and cerebral arteriosclerosis show different patterns of distribution with regard to the sexes, the geographical origin, and the time since immigration

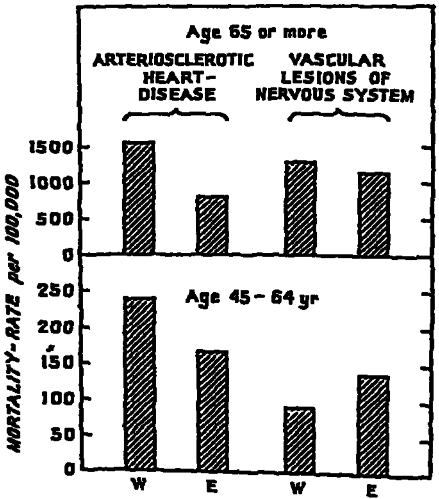

Fig 1.—Mortality-rates (per 100,000) in two disease- and age-groups, by continent of birth (1953-54) E, oriental, W, occidental.

MORTALITY-RATES (PER 100,000) BY TWO DISEASE- AND AGE-GROUPS

Factor	Group	Arteriosclerotic heart-disease						Vascular lesions of central nervous system					
		Age 65 or more			Age 45–64			Age 65 or more			Age 45–64		
		Rate	Difference	Significance of difference*	Rate	Difference	Significance of difference*	Rate	Difference	Significance of difference*	Rate	Difference	Significance of difference*
Continent of birth (average 1953–54)	*Occidentals*	1532±41	790±72	+	232±8	72±15	+	1237±37	106±69	–	86±5	49±10	+

Sex and continent of birth (1954)	*Occidentals* Males	2040±100	1024±114	+	355±19	256±22	+	1199±77	2±103	–	91±9	11±13	–
	Females	1015±62			99±10			1197±68			80±9		
	Orientals Males	638±84	103±113	–	216±26	104±33	+	847±95	114±140	–	97±18	38±27	–
	Females	535±76			122±19			961±102			134±21		
	All males	1627±73	737±67	+	308±15	211±18	+	1127±61	14±83	–	90±8	10±12	–
	All females	890±48			98±9			1142±56			100±9		
Continent of birth and time since immigration (average 1953–54)	*Occidentals* Newcomers	1399±65	149±79	–	200±11	12±15	–	1097±58	72±70	–	93±8	27+9	+
	Veteran settlers	1250±46			212±10			1024±42			66±5		
	Orientals Newcomers	544±50	47±82	–	141±12	3±26	–	930±65	255±101	+	132±12	38±43	–
	Veteran settlers	591±67			138±21			674±71			94±17		
	All newcomers	1235±49	110±61	–	178±8	24±12	–	1028±43	170±61	–	107±7	38±9	+
	All veteran settlers	1125±40			203±9			960±37			69±5		

* Criterion of significance 2×standard error

From the table and figs 1–3 it appears, as the most characteristic and most unexpected feature, that for arteriosclerotic heart-disease, in both the age-groups studied, there is a distinct preponderance of people of occidental over those of oriental origin,* but this preponderance is absent or even reversed in direction for vascular lesions of the nervous system (fig 1)

Similarly there is an excess of males over females in all the age and ethnic groups for the coronary localisation, but not for the cerebral one (fig 2)

Moreover, the rates are more or less similar in newcomers to the country and in veteran settlers, for coronary arteriosclerosis in the two age-groups studied in orientals and occidentals alike, whereas there is an excess of newcomers in the corresponding deaths from cerebral arteriosclerosis (fig 3)

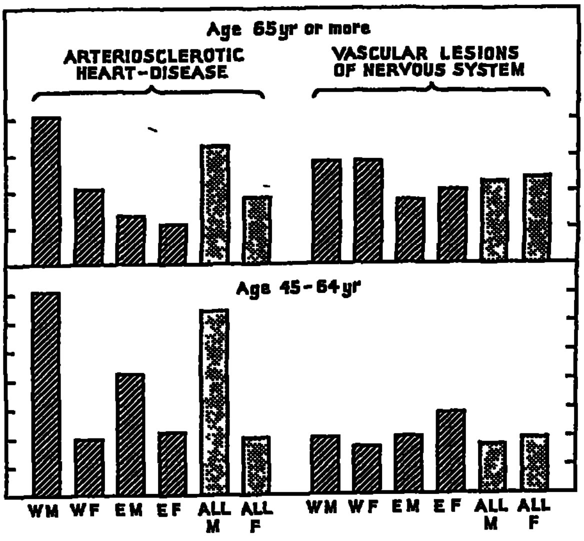

Fig 2—Mortality-rates (per 100,000) in two disease- and age-groups, by sex and continent of birth E, oriental, W, occidental, M, male, F, female

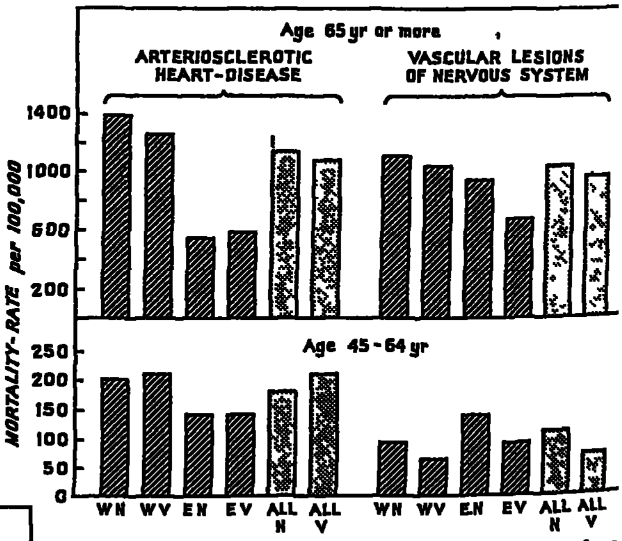

Fig 3—Mortality-rates (per 100,000) in two disease- and age-groups, by continent of birth and time since immigration E, oriental, W, occidental, N, newcomers (after 1948), V, veteran settlers (before 1948)

If any conclusion may be drawn from these data it must be tentative It seems that coronary and cerebral arteriosclerosis, following as they do different epidemiological patterns, may be two basically different phenomena It has also been suggested that we may be dealing with different intensities of one and the same pathological process

Thanks are due to Prof F Dreyfus, deputy director of the medical department A of the University Hospital, *Jerusalem*, and to Dr F Yekutiel, director of the epidemiological department of the Ministry of Health, for their kind assistance and constructive criticism

---

* The terms "orientals" and "occidentals" are used here to signify the broad groups of Jewish immigrants to Israel with country of birth on the Asio-African and European continents respectively The second group coincides roughly with the accepted term of "Ashkenasian" Jews

AN UNUSUAL CASE OF CARDIAC INJURY

R L GUPTA

FORMERLY REGISTRAR, DEPARTMENT OF THORACIC SURGERY,

R I KEEN
M B Sheff , F F A R C S
SENIOR REGISTRAR, DEPARTMENT OF ANÆSTHETICS

CITY HOSPITAL, NOTTINGHAM

CARDIAC injuries of every conceivable type have been described over the years No claim is made for the uniqueness of this case, its interest lying chiefly in the mode of causation

Case-report

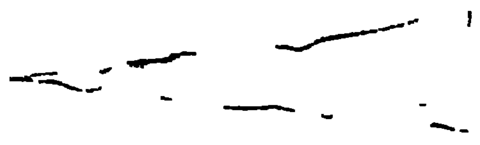
A man, aged 32, of good physical stature, was admitted to hospital at 1 30 P M on Aug 5, 1957, in a collapsed state At about 11 45 A M that day he had been in a greenhouse helping his brother, who was replacing some glass tiles The height of the roof was 14 ft While the patient was standing directly below, his brother accidentally broke a pane with his elbow, sustaining no injury himself The patient immediately cried out that he was hurt, and collapsed

On examination he was gravely shocked, pulse and blood-pressure being unrecordable, respirations gasping, and mucosæ pale and cyanosed There was no distension of neck veins A small skin wound about 2 cm long was noted in the right third intercostal space close to the sternal border Blood was welling out of this wound, and the clothing was heavily bloodstained Radiography during resuscitation showed a large right-sided effusion and displacement of the mediastinum to the left Aspiration produced 4 pints of blood After the rapid infusion of 5 pints of plasma the patient's condition somewhat improved, his systolic blood-pressure now being 70 mm Hg As soon as blood was available for transfusion, he was taken to the operating-theatre

Anæsthesia was induced and maintained with 50% nitrous oxide and oxygen, a cuffed endotracheal tube having been passed under topical analgesia Respiration, after having been assisted, readily became controlled on a closed circuit, without any need for relaxants Intravenous infusions were continued into both external jugular veins, no other veins being accessible

Operation —Right thoracotomy was done in the supine position with a slight lateral tilt and a head-down tilt of 20° The incision was in the third intercostal space The right internal mammary artery and the right phrenic nerve were found severed, and the pleural cavity full of blood There was a laceration in the pericardium and in the right auricular appendix A triangular piece of glass 6 5 cm long, 1 8 cm wide at the base, and pointed at the apex, shaped like a scalpel blade, was found embedded in the right auricular appendix The middle lobe in the path of the splinter was lacerated at several places The auricular appendix, from which blood was gushing, was clamped, the internal mammary artery was ligated, and the lacerations of the lung and right auricular appendix were repaired, complete hæmostasis being achieved The wound was excised, and the incision was closed in layers, with underwater drainage

Postoperative course —At the end of the operation the patient's condition was satisfactory, his blood-pressure being 90/60 mm Hg 10 pints of blood had been given by then The transfusion was continued, and oxygen was administered with Boyle's apparatus The patient was breathing adequately and was now conscious For two hours his condition remained unchanged, then his blood-pressure began to fall No response was obtained to noradrenaline, but intravenous hydrocortisone brought about a temporary improvement The systolic blood-pressure, however, did not rise above 80 mm Hg At 12 45 A M the patient collapsed and, despite cardiac massage, died About 3 pints of blood was in the drainage bottle In the postoperative period 5 bottles of blood and 3 of plasma were given, bringing the total to 15 and 8 respectively At necropsy Dr W M F Hall confirmed the operative findings and the satisfactory repair of the damage, and found 2 pints of blood in the right hemithorax



Glass splinter (actual size)

Comment

Massive hæmorrhage into the pleural cavity and externally usually causes immediate death by exsanguination, and injuries causing such hæmorrhage in civilian life are rarely seen in medical practice (Chamberlain et al 1956) In the present case the cause of death was probably prolonged hypotension before treatment, this produced irreversible shock, which only responded temporarily to attempts to raise the blood-pressure

It is unusual for so small and so light a body (see figure) to cause a fatal and so extensive an injury The initial velocity of the fragment could not have been great The splinter fell about 10 ft, probably it was a bigger piece and acquired sufficient velocity to pierce a shirt, a vest, and an undoubtedly muscular chest wall Also its fall was vertical, and a superficial, and perhaps larger, portion of this splinter broke off at the level of the body wall, leaving the main offender inside to do the fatal damage

Our thanks are due to Mr J S A Linton, under whom the patient was admitted, and to Mr A C G Rothera, H M Coroner for the city of Nottingham, for permission to publish

Preliminary Communication

APPARENT INCREASE IN BLOOD-PROTHROMBIN DURING EXTRACORPOREAL BYPASS AND DURING SLOW COAGULATION IN SILICONED CONTAINERS

POSTOPERATIVE bleeding is becoming more common because of the more extensive operations now attempted It is a very serious complication when it takes place after an extracorporeal bypass for open cardiac surgery

During research into this problem fibrinogen (measured by spinning out the fibrin on a weighed glass rod and then drying and reweighing the rod), platelets (measured by the method of Brecher and Cronkite [1]), antihæmophilic globulin (measured by the method of Pitney [2] as modified by Mustard [3]), and prothrombin (measured by the two-stage method of Biggs and Macfarlane [4] and the acid-precipitated-globulin method of Douglas [5] as modified from the original method [6]), were studied in an effort to ascertain what was happening in the extracorporeal

circuit It was found that, during thirty minutes on the extracorporeal circuit in the dog, the fibrinogen decreased to 53–63% of normal,[7] the platelets decreased to 55–70% of normal,[7] the antihæmophilic globulin decreased to 40–64% of normal,[3] and the prothrombin apparently increased during the first twenty minutes on the circuit and then decreased in parallel with the other factors

This apparent increase in the amount of prothrombin was first discovered with the two-stage prothrombin-area technique, but since there was such a high single peak in the first minute, it was felt that this increase was due to the inaccuracy which would occur in the area under that peak As a result of this, the acid-precipitated-globulin method was used, and this confirmed the previous results The blood in the extracorporeal system was inhibited from clotting by the use of heparin (Connaught) 4 I U per ml of blood The samples of blood were taken directly from the pump in siliconed needles and syringes during the operation

It is felt that these results indicated that the blood was clotting slowly in the extracorporeal circuit In an effort to confirm this, blood was taken into a siliconed beaker, where it was allowed to clot slowly Samples were taken from this and placed in siliconed test-tubes containing heparin (Connaught) 4 I U per ml of blood The acid-precipitated-globulin method of determining prothrombin was applied to samples taken every minute during the time that the blood was fluid This method gave results which follow exactly the previous findings, showing that, during the clotting of the blood, the thrombin yield of the acid-precipitated globulin increased to an amount greater than twice the initial value This was accomplished within the first two minutes with the siliconed-flask technique and within the first twenty minutes on the extracorporeal circuit These findings were confirmed again by the two-stage prothrombin technique

The extracorporeal circulation system and the siliconed-vessel techniques provide an excellent means of studying delayed coagulation of blood In using Douglas' acid-precipitated-globulin method and the two-stage prothrombin-area method we are measuring the amount of thrombin generated in the samples It is not yet clear that this is due to the activation of a "prothrombin precursor," as suggested by Bordet[8] and Quick and Stefanini[9] or to the activation of a prothrombin "converter" which in turn increases the yield of thrombin from the prothrombin, thus confirming the work of Ware and Seegers[10]

We wish to thank Dr S H Jackson for his valuable assistance and for the use of his laboratory, and the Ontario Heart Foundation for supplying funds to one of us (W T M) for this research

New Inventions

APPARATUS FOR REMOTE INJECTION IN RADIODIAGNOSTIC PROCEDURES

IT is now commonplace for radio-opaque media to be injected into patients during radiography, and often the same operators are exposed repeatedly to X rays Those who undertake this form of injection are wise to protect themselves from undue irradiation by using some means of doing this from a distance[1] We describe apparatus designed for this purpose

If safety is to be obtained by distance, the needle must be connected to the syringe by a considerable length of tubing If this tubing is thick and heavy it drags on the needle and displaces it The ideal tubing should be light, transparent, and capable of resisting any pressure the syringe can deliver, moreover it should withstand repeated sterilisation by heat, including the autoclave, and no special skill should be required when its replacement is necessary Nylon tubing of a bore slightly greater than the needle fulfils these requirements admirably (no 4 gauge—*Portland Plastics*) *Special connectors* are used to join needle and syringe to this tubing without any reduction in the effective lumen, flanging of the tube ends is not necessary

The nylon tubing passes through the connector and its rubber diaphragm (fig 1), when the screw collar is firmly tightened the rubber is compressed and grips the tubing Although it is possible forcibly to drag the tubing out, this requires far rougher usage than is likely in practice, certainly the maximum hydraulic pressure likely to arise within the tube system is unable to push it out As the connectors have Luer lock ends, the whole system is extremely secure The connector nearest the syringe incorporates a tap to prevent either emptying by siphonage or unwanted entry of arterial blood Thus, the basis in any set for radiodiagnostic injection procedures is an all-glass Luer-lock syringe and nylon tubing with connectors, the nylon tubing may be as long as suits the safety requirements of the operator During sterilisation the tubing must be

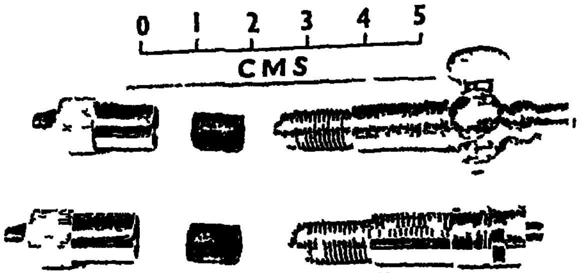

Fig 1—Component parts of a pair of nylon tubing connectors

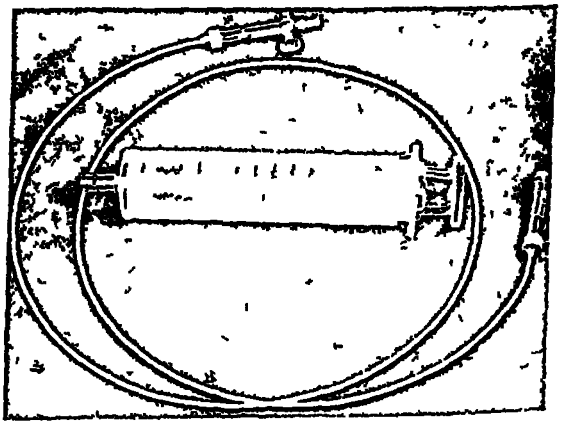

Fig 2—Basic set for radiodiagnostic injection procedures

---

[1] Code of Practice for the Protection of Persons Exposed to Ionising Radiations H M Stationery Office 1957

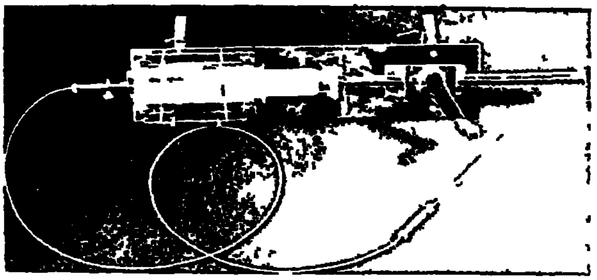

Fig 3—Syringe-pushing device

removed from the connectors because otherwise, softened by the heat, it collapses within them

The provision of a basic set (fig 2) common to a number of techniques, and requiring only simple additions for certain variants, has been found to simplify the task of the nurses in preparing these sets, moreover, the design has reduced maintenance difficulties to a minimum The only parts in the basic set which need occasional replacement are the nylon tubing and the rubber diaphragms in the connectors—the former is simply cut from a roll of 'Portex' no 4 nylon tubing, and the latter are laid into the screw caps after removal of the old diaphragms

Though the syringe may be held in the hand, we have found that for the abdominal aortogram it is much more convenient to use a mechanical device (fig 3) This is not to say, however that we condone delivery of the dye with great force. We believe that high pressure is neither necessary nor desirable and that dissection of the aortic wall [2] may be avoided by use of apparatus which works at low pressure and imparts an instant sense of resistance if the needle is not properly situated Our apparatus has been designed to give a slight mechanical advantage and to retain a sensitivity that is lost if the syringe is pressed home strongly Injection is conducted effortlessly with one hand almost at arm's length, with no tendency to drag on the tubing and no fear of the syringe breaking in one's hand

Fig 3 shows our device, which in its essentials is a "window winder" mounted on a platform so that rotation of the handle extends the thrust arm against the syringe piston, attached to the platform are screw clamps for fixing it to an X-ray table or any other convenient support The syringe (50 ml Luer lock/Summit) is retained in its supporting channel by two spring-clips and is prevented from sliding by a vertical end-piece The thrust arm meets a stop just before the syringe closes completely and avoids this usual source of syringe breakage We do not use an automatic switch coupled to the X-ray machine, but this could be included without difficulty

In our experience, during X-ray exposures the operator is about three feet from the patient, and when one abdominal film and two films of the patient's lower limbs are taken the total radiation received by the operator is less than a milliröntgen This dosage is reduced to a thirtieth by wearing a lead rubber apron, as we always do The radiation dose is then about 1/9000 of the maximum permissible weekly dose of 300 milliröntgens [3]

The same apparatus, including the "syringe pusher", is used in this hospital for splenoportal venography and has been found entirely satisfactory The same basic set, with the addition of appropriate needles and cannulæ, has been used repeatedly for femoral arteriography, peroperative cholangiography, and presacral retroperitoneal insufflation of oxygen For these procedures the syringe is, of course, operated by hand

For oxygen insufflation, a necessary addition to the set is a Luer-lock two-way tap, the side arm of which is connected to a bag of oxygen. The original technique used a syringe, two-way tap, and needle locked together [4], the insertion of nylon tubing is an improvement as it enables the operator to sit comfortably alongside the patient The nylon tubing, resistant as it is to collapse by suction, allows instant detection of any blood drawn back into its lumen

We are indebted to Dr F T Farmer for the data on radiation dosage

We acknowledge the valuable assistance of Messrs Robert Whitelaw (Newcastle) Ltd, 44, Great North Road, Newcastle upon Tyne, 2, in the development of the connectors, this firm has undertaken to supply all the equipment referred to The nylon tubing may also be obtained from its makers—Messrs Portland Plastics, Bassett House, Hythe, Kent.

Reviews of Books

Sherrington Physiologist, Philosopher, and Poet

LORD COHEN OF BIRKENHEAD, M.D, D SC, LL D, F R C.P, professor of medicine, University of Liverpool Liverpool University Press 1958 Pp 108 17s 6d

IN 1948, on the occasion of the ninetieth birthday of Sir Charles Sherrington, the council of the University of Liverpool instituted a biennial lectureship in his honour, and to commemorate his association with that university, as professor of physiology, for eighteen years This volume contains the three addresses in this series which were delivered by the professor of medicine, Lord Cohen of Birkenhead

The last word about Sherrington's contributions to physiology will not be written for many years to come His *Integrative Action of the Nervous System* has been knowledgeably compared with such scientific milestones as Harvey's *De Motu Cordis* and Newton's *Principia* Lord Cohen's lectures give an admirable and fascinating outline of this talented and varied life Two episodes alone need be mentioned to illustrate the versatility and enterprise of Sherrington there are good grounds for believing that he was the first doctor in this country to use the antitoxin, which Behring had discovered, to save a patient dying of diphtheria, and when, during the 1914–18 war, he was asked to study fatigue in munition workers, he tackled the problem by working in a shell factory, as an ordinary labourer, twelve hours a day, for three months

All who knew Sherrington, and all who read in this book of his contributions to science and literature, will feel that Lord Cohen chose aptly when he applied to him an epitaph once used by Samuel Johnson of another doctor, philosopher, and poet *Nullum quod tetigit non ornavit*

Tuberculosis in Animals and Man

A Study in Comparative Pathology JOHN FRANCIS, D SC., M.R C.V.S, professor of veterinary preventive medicine, and dean, faculty of veterinary science, University of Queensland London Cassell 1958 Pp 357 105s

IN this book Professor Francis has gathered much information of importance to veterinary surgeons and of great interest to doctors The first part is about bovine tuberculosis, and its prevalence in cattle in different countries and in different breeds is described in detail The section on pathogenesis and pathology emphasises how thoroughly the early investigators (including the British Royal Commission on Tuberculosis, which is much quoted) studied the disease in calves, and the account of immunisation includes a comparison of the effects of B C.G and the vole-bacillus vaccine in man Explanations follow of the difficulties of detecting tuberculosis in cattle and of the methods used in different countries for suppressing the disease as completely as possible over a period of years The chapter on bovine-type infection in man is largely a study of the relationship between the types of tubercle bacilli and of the possibility of interchange between the human and bovine types, and the evidence is assembled for the view that, where there is heavy exposure to human droplet infection, ingestion of tuberculous milk enhances resistance to pulmonary tuberculosis in the general population

Thereafter, considerable space is devoted to tuberculosis in all other animals about which there is reliable information, from monkeys to edible frogs, taking in, among others, elephants, camels, and mice A description of avian tuberculosis in domestic and wild fowls is included, and the incidence of avian-type infection is often mentioned throughout this part of the book because of its frequency in sheep and pigs, especially in Denmark and the United States, where bovine tuberculosis has been almost eradicated

A final short section compares the pathology and epidemiology of tuberculosis in animals and man Professor Francis classifies animals according to the general pathological picture, and he finds that those animals in which more or less typical tubercles are formed develop a fairly high degree of allergy Primitive man faced with civilisation, and monkeys taken into captivity, are very liable to fatal infection a primary complex develops and their histological reactions are similar Experimental infections in guineapigs and rabbits show the same reactions Urban man and all bovidæ come into the next group, which shows moderate susceptibility to infection and reacts with typical tubercles Horses are much more resistant to infection and their lesions consist of chronic granulation tissue without typical tubercles In most other animals there is no tubercle formation, though some may show necrosis and liquefaction, and many are very resistant to infection Professor Francis also discusses the ideal experimental animal, the virulence of tubercle bacilli for various species, and natural infections in such species An appendix gives brief summaries and a complete list of the reports of the Royal Commission on Tuberculosis

Professor Francis has ranged very widely and brought together much scattered material which he has skilfully woven into a very valuable book Some readers may regret that he has not expressed more definite views on some of the controversial issues that abound in this subject, but the difficulties of doing so are very apparent All who are involved or interested in the eradication of tuberculosis, especially from the animal world, will be grateful for the help and stimulus of this book

Liver-Brain Relationships

IAN A BROWN, M D , PH D , associate professor of neurology, University of Minnesota Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1957 Pp 198 50s

THE new and expanding views on liver-brain relationships have been elaborated from a thesis to a book by Dr Brown A remarkably international bibliography and a comprehensive historical introduction have survived the transformation best Apart from a chapter on Wilson's disease, the book is devoted to the neuropsychiatric syndrome of hepatic coma British readers will be pleased by the acceptance of factors other than liver failure as causes of hepatic coma, despite the complex nomenclature of the various "hepatoencephalomyelopathies" that this entails The importance of alterations in personality which may precede coma is emphasised, very justly, to a greater degree than is usual

Dr Brown writes at length on his personal experience in 42 cases, a series which is not large or representative enough for this complex subject, and which directs too much attention to routine tests of liver function, neglecting more relevant investigations (such as portal venography or blood-ammonia studies) The electroencephalographic data are somewhat scanty, and neuropathologists may be surprised at the stress laid on demyelination rather than the Alzheimer-cell phenomenon as typical of hepatic coma The possible metabolic basis of hepatic coma is reviewed extensively, though at times uncritically

The book illustrates vividly the neuropsychiatric aspects of hepatic disease—a particularly important consideration in the United States, where liver disease is the third commonest cause of death In this country, those interested in neurology, psychiatry, and gastroenterology will find it valuable, and it can be commended to a wider public as a good example of the complexities of this kind of research

Sentenced Without Cause

DAVID ROXAN London Frederick Muller 1958 Pp 255 18s

Too few people realise that, despite the absurd complexities of existing legislation, detention in one of our less pleasant mental-deficiency institutions may be brought about in a very perfunctory way It is easy to describe a person of uncertain I Q as "feeble-minded" or another with some character eccentricity as a "psychopath" To lock up such people under an unenlightened regime is likely to produce behaviour abnormalities which may then be held to justify further detention What is called "treatment" may be a system of graded incentives to good behaviour in a prison-like atmosphere working up from an extreme of degradation

Some inadequacies of the present system are vividly described in this book, which recounts the life of an orphan who trod the gloomy trail from one bad institution to another via casual intelligence tests and brief psychiatric interviews, ending (illegally and undeservedly) at Rampton Doubtless there is much special pleading here questions are begged and the writing is emotionally biased, one wonders whether the subject of the work has shown himself, since discharge, to be as normal as the book makes out (though after his sad life it would be remarkable if he were) In all, however, the picture is probably true, and it may help to produce that climate of opinion that seems necessary before reforms can be achieved Until more money is provided for this branch of the health service, these deficiencies cannot be eradicated

The author asks whether this is an isolated instance or whether, among the 30,000 detained in such institutions, there are many well able to take their place in society This question is impossible to answer under circumstances where even psychiatrists are sometimes refused access, but there is reason to suppose that the situation is by no means satisfactory

---

Mental Disorder (National Association for Mental Health, London 1958 Pp 35 3s)—The report of the Royal Commission on the Law Relating to Mental Illness and Mental Deficiency is surveyed in this handy booklet by Mr C H Rolph He threads a devious but always intelligible course through the tangle of existing laws and opinions, he gives a few views of his own and makes the whole affair clear and of interest to the layman Obviously there is a wide public for such a work, particularly among those working on the fringes of the welfare services, who find the report itself (with some 300 crowded pages) a formidable undertaking He may be too uncritical of the section on psychopaths, perhaps the weakest part of the report, but he has done his best to take in the contrary views that have been expressed since it was published a year ago he is certainly right up to date Reviews, criticisms, evaluations, and opinions on the Royal Commission's findings are thick on the ground, but this is a pamphlet well worth having

5-Hydroxytryptamine (London and New York Pergamon Press 1958 Pp 253 60s)—These proceedings of a symposium held in London last year form a useful summary of the information available about an interesting and still mysterious substance Since last year observations on the action of 5-H T relative to intestinal movements may have lightened the mystery, but it is far from clear why 5-H T should be so widely distributed a cell component, or why it should be relatively concentrated in certain parts of the central nervous system The symposium dealt with the occurrence and distribution of 5-H T , its storage and release, and its actions on the cardiovascular system, on nerve-endings and ganglia, and on gastric secretion Its significance in carcinoids was discussed, and its role in anaphylaxis Its central actions were considered as well as its central and peripheral antagonists Thus, the symposium covered much ground and this report, edited by Dr G P Lewis, is a valuable book of reference

THE LANCET
LONDON 31 MAY 1958

The Tourniquet

THE tourniquet is associated in many minds with the era of blood-letting, leeches, and cutting for stone, but even today a Samways tourniquet dangles as a sinister threat from the foot of many an amputee's bed. It is a device which has rendered useful service to surgeons, and it remains a favoured if occasional aid. The original tourniquets of **MOREL**[1] (1674) and **JAMES YOUNG**[1] (1678) were rude contrivances "a wadd of hard linen cloth, or the like, inside the thigh, a little below the inguen, then, passing a towel round the member, knit the ends of it together, and with a balloon or bedstaff, twist it till it compress the wound". **PARÉ**[2] (1561) recommended "a strong broad fillet like that which women usually bind up their haire", and the mechanistic 19th century developed formidable metal gadgets with screw compression. **ESMARCH**'s original elastic band consisted of a rubber tube as thick as a finger. it was **VON LANGENBECK** who suggested the modern type of flat elastic bandage which gives more diffuse pressure. Finally the pneumatic cuff was modified to provide ischæmic compression. this is the most satisfactory type since the pressure can be accurately adjusted and maintained, but it may leak, and it is cumbersome and is not quickly applied. When the cuff is applied to the arm a pressure of 250 mm Hg is usually sufficient, in the legs 300 mm.

The tourniquet is used to staunch traumatic hæmorrhage or to ease dissection in elective surgery. In the control of severe traumatic bleeding a tourniquet has a very limited place. Most types of hæmorrhage are readily and more safely controlled by elevating the limb and by local digital or pad pressure. Only when such measures fail should a compressive band be considered. An inefficient Spanish windlass (a popular type for first-aid kits) may through venous congestion increase blood-loss, or through excessive pressure, especially in the upper arm or below the knee-joint, it may cause nerve damage and by long periods of limb ischæmia lead on release to "tourniquet" shock, gangrene, or precipitous hypotension. Most wartime surgeons felt that more lives were lost than were saved by tourniquets. As an emergency measure soft rubber tubing ($^1/_2$ inch) was generally recognised as simple and effective, although this method was never officially approved. A length of about six feet was applied with moderate tension over a towel, taking four turns around the limb. One particular indication was the high-pressure hæmatoma following injury to a vessel. wartime experience showed that more damage was done by pressure and infiltration from the hæmatoma than by application of a tourniquet for a reasonably short time.

The place of the tourniquet in elective surgery is more debatable. Many, if not all, orthopædic surgeons like to undertake nerve repairs, hand surgery, meniscectomies, and other selected operations where possible in a bloodless field. (But in some other operations—notably repair of fractured olecranon or patella—it is a nuisance rather than an aid.) **PANNETT**[3] expresses disquiet at what he considers the overuse of the tourniquet. What in fact are the dangers? First, pressure damage—radial or median nerve palsy in the arm being commoner than lateral-popliteal-nerve palsy in the leg. But such palsies are extremely rare if a pneumatic cuff is used in the upper limb and if compression by an Esmarch bandage in the lower limb is restricted to the thigh, even for foot operations, in each case the limb being protected by a towel. Tourniquets placed about the forearm and lower leg are often ineffective, since bleeding from incompressible interosseous vessels is likely to continue. In the occasional case where nerve lesions develop, spontaneous recovery of function is the rule[4], but **MOLDAVER**[5] reported seven cases with complete and permanent nerve lesions, in three compression had been applied by a rubber tube, in two by an Esmarch bandage, and in two by an inflatable cuff. All the palsies were in the upper limb, where the nerves are more liable to be squeezed against bone.

The most important thing about putting on a tourniquet is to take it off. This involves a clearly understood theatre routine. a tourniquet-book with times of application and release, and a tourniquet fixed to the table, the direct responsibility of one member (e g, the surgeon or anæsthetist), are well-tried methods. The period of safe compression for any individual patient is largely unknown. It varies with age, environmental and body temperature, and the type of limb damage. **WOLFF** and **ADKINS**[6] suggested that in exceptional cases up to 6 hours was safe, they observed no case of gangrene, nerve damage, or thrombosis in a thousand battle casualties (albeit in healthy young men) in which a tourniquet was left untouched for up to 4 hours. In elective surgery a safe rule would seem to be to release tourniquets within the hour, and only very exceptionally should the limit be extended to 2 hours. **PANNETT** holds that infection is more likely to ensue in a limb dissection performed in an ischæmic field where "the power of immune response is in abeyance"[3]. There is no clear evidence on this point, but there was an impression among some battle surgeons that anaerobic infection was commoner where a tourniquet had been applied. In the other scale is evidence that application of a tourniquet before manipulating fractures diminishes the risk of fat embolism. The postoperative oedema and pain that are said to follow removal of a tourniquet are often due to overtight bandaging.

What place, then, has the tourniquet, and, in brief, what precautions are necessary? It may be used when it makes an operation decidedly easier, and therefore quicker and safer for the patient. Clear-cut rules about its application and release should be known by all the theatre staff. An Esmarch bandage should be restricted to the thigh. There is no place for below-knee tourniquets, and on the upper limb only a pneumatic cuff should be used A tourniquet should never be put directly on the skin but over towelling The maximal period of application is 2 hours, and 1 hour should rarely be exceeded A distinct contraindication is in peripheral vascular disease and the elderly, when limb vessels may fracture or thrombose For emergency use with severe arterial bleeding a tourniquet should be applied as early as possible after the injury The patient should be given the highest priority for transportation to the nearest hospital, and the time of application should be written on the patient's forehead and the receiving-room informed directly of its presence If the patient is shocked from hæmorrhage the tourniquet should not be removed before a plasma-expander, preferably blood, is already running in It is folly to compromise a life in an effort to save a limb

As with many other surgical devices a tourniquet properly used may save lives and limbs if used unthinkingly it may cause serious and irreparable damage

Iron Deficiency in Man

IRON deficiency is one of the commonest debilitating diseases affecting man It may be due to chronic blood-loss (as from hæmorrhoids), to inadequate iron in a defective diet, to increased iron requirements (as in pregnancy), to defective iron absorption (as in steatorrhœa), and sometimes to imperfect utilisation The efforts of many interested workers have provided us with much quantitative information about iron absorption and metabolism JOSEPHS[1] has lately compared the four main methods of studying iron absorption The original balance method determined by chemical estimation the amount of iron ingested and the amount recovered from the fæces This method, which was used by MCCANCE and WIDDOWSON[2] many years ago, is difficult because the technique of estimation needs exceptional care and all clinical balances need great vigilance, but it has the advantage that the observations can be continued for as long as is necessary and can be repeated The balance technique utilising radioactive-iron isotopes incorporated into iron salts or food is much easier but cannot be repeated on individual patients because there is a limit to radioactive doses Another method is to estimate iron absorption from the rise in hæmoglobin in the patient's blood the implied assumption that all absorbed iron is used only for hæmoglobin formation may not always be correct, but NEERHOUT et al[3] showed that in dogs 95% of absorbed isotope-tagged iron is present in the red-cell mass fourteen days after feeding The last method is to follow changes in serum-iron after giving a test dose JOSEPHS considers that results from this method are of only limited value, a good rise of serum-iron level after the test dose clearly indicates good absorption, but the reverse is not necessarily true JOSEPHS concludes that the chemical iron-balance method, for all its difficulty, has given results that constitute the standard for judging other methods, and it is by this method and the isotope-balance techniques that most of our information has been acquired

GUBLER[4] pointed out that the average adult human body contains about 4 5 g of iron Hæmoglobin accounts for 73% of this iron and myoglobin in muscle tissue for 3 3%, "storage iron" (ferritin, hæmosiderin, and "unaccounted iron") present mostly in liver, bone-marrow, and spleen comprises 23 5%, and the remaining 0 2% is "parenchymal" iron—cytochrome, catalase, peroxidase, found in all tissues In the normal adult 27–28 mg of iron is released daily from the breakdown of hæmoglobin, and all, except about 1 mg, is utilised again for fresh hæmoglobin formation The normal adult excretes about 1 2 mg of iron daily, and the normal woman additionally loses iron in the menstrual loss at the rate of 1 mg daily, so the iron requirement of women is double that of men In pregnancy no iron is lost in the menses, but an average of 2 7 mg daily has to be provided for the fœtus During the period of growth from infancy to adolescence larger amounts are needed since expansion as well as excretion has to be covered, and for the first twenty years of life an additional 0 3–0 6 mg daily must be provided GUBLER cites the National Research Council's estimate that, allowing for only 10% absorption of iron from the food, daily amounts of iron needed are for infants 1 mg per kg body-weight, for children 0 6 mg per kg, for adult men 10 mg, for adult women 12 mg, and for pregnant women 15–20 mg CARL MOORE[5] has stated that the normal adult diet in the U S A yields about 12–15 mg of iron daily It is clear that most women in the reproductive period of life have a precarious iron balance, and undue menstrual loss or poor diet inevitably produces a negative balance which eventually shows as iron-deficiency anæmia Conditions such as diarrhœa, infection, and steatorrhœa will also soon cause excessive iron loss But in men, and in women past the menopause, iron-deficiency anæmia nearly always denotes blood-loss, and the cause has to be diligently sought Dr Bedford's paper in our present issue shows that in old people anæmia from slight bleeding into the alimentary canal may be far commoner than is supposed

Accordingly it is obvious why iron-deficiency anæmia is so common Fortunately we have several ways of giving iron efficaciously, and iron alone is adequate treatment for uncomplicated iron-deficiency anæmia Apart from vitamin C, there is no firm evidence that the addition of vitamins, such as those of the B complex, or of trace metals or liver fractions makes any difference to the response On the other hand, there are many recommended iron preparations, and the fact that new ones keep appearing indicates that we still lack one that is completely satisfactory One of the main difficulties is that oral iron preparations are liable to cause troublesome gastrointestinal side-effects such as nausea, heartburn, diarrhœa, or constipation These side-effects often cause the patients to stop taking their pills, and, since they sometimes fail to confess unless directly questioned, the physician may regard them as "refractory" cases and resort to intramuscular or intravenous iron preparations There are various ways of minimising these side-effects The most usual is to insist that the iron tablets are taken with meals, but **FRANKLIN** et al [6] point out that this reduces the effectiveness of the iron preparation Another way has been to use organic instead of inorganic iron salts—e g, ferrous gluconate or succinate instead of ferrous sulphate **O'SULLIVAN** et al [7] showed that the relative freedom from side-effects of the organic salts was due to the fact that they contain less iron Where equal iron doses were given under comparable conditions, all these ferrous salts were about equally effective, and the troublesome side-effects affected about 13% of their patients, whichever iron preparation was used The ferric salts are better tolerated so long as the dose is kept down, but they are definitely less effective and treatment takes longer

[5] Moore, C V *Amer J clin Nutr* 1955, 3, 3

FRANKLIN et al [6] have lately described their results with an oral chelated-iron compound Chelation has been used before, but mainly to try to prepare safe and effective parenteral iron drugs **WILL** and **VILTER** [8] used sodium iron edetate, a chelated compound, as an oral substitute for ferrous sulphate, they found that it released iron satisfactorily and was notably free from unpleasant side-effects, but interchange between iron and calcium occurs with this compound, and, though the effect is small, it is probably best avoided The complex used by **FRANKLIN** et al was an iron choline citrate containing 12 5% of elemental iron—about the same as in ferrous gluconate (11 5% Fe) This compound was put up in tablets containing 40 mg of iron, and three to six tablets a day were given *between* meals In 18 patients receiving 160 mg Fe daily as iron choline citrate, the average hæmoglobin gain per day was 0 14 g per 100 ml —which is of the same order as the figure obtained by **O'SULLIVAN** et al for ferrous gluconate or sulphate None of these 18 patients complained of gastrointestinal upsets A larger group of 88 patients in hospital were given two tablets three times daily (240 mg Fe) and 6 complained of mild nausea, diarrhœa, or constipation, the therapy was continued despite these symptoms, and they soon disappeared Animal experiments indicate that the choline citrate complex was less toxic than ferrous sulphate or gluconate This chelated-iron complex may well have therapeutic possibilities, and enable us to reduce still further the number of patients who have to be given parenteral iron How widely iron choline citrate is used may depend on its cost Ferrous sulphate is very cheap, ferrous gluconate costs about five times as much as sulphate, ferrous succinate and fumarate still more Parenteral treatment is still considerably more expensive than oral treatment. It would clearly be uneconomic to substitute an expensive iron compound just to eliminate the side-effects that involve 13% of patients, but chelated iron may reasonably be kept in reserve for intolerant patients

Every doctor sees patients with iron-deficiency anæmia, and, nowadays, every doctor can have a scheme for treating them satisfactorily Most of the patients will respond to oral iron, and, as **O'SULLIVAN** et al showed, relatively small doses yielding about 210 mg elemental iron a day are sufficient, this means three tablets of 0 2 g ferrous sulphate or four tablets of 0 3 g ferrous gluconate daily The 10% or so of patients who get gastrointestinal upsets with these drugs can be given ferrous fumarate or succinate or larger doses of a ferric hydroxide preparation, though they may still get symptoms with these alternatives These difficult patients and those who do not respond to oral iron can be treated with the intramuscular iron-dextran compounds, which have gained deserved popularity **GRIMES** and **HUTT** [9] have shown that almost all the absorbed iron given in this way is utilised for hæmoglobin formation, but only 60% of an injected dose is absorbed quickly, the remainder being absorbed slowly over a period of perhaps four weeks **EVANS** and **RAMSAY**,[10] studying absorption of iron-dextran in pregnancy, found evidence of maximum absorption from the injection site in ten to twenty days, 80% absorption within three weeks, and residual absorption for as long as six months These results indicate that intramuscular iron-dextran is an efficient way of giving iron, but, to allow for the relatively slow absorption of 40% of the injected dose, it is customary to allow 40 mg of iron for every hæmoglobin deficit With such a scheme every patient with iron-deficiency anæmia should respond to treatment, if they do not the diagnosis may not be correct, and the patient should be referred to the nearest suitable clinic without delay

Annotations

STREPTOCOCCAL SAGA

THE severity and frequency of streptococcal respiratory infections seem to be slowly declining, at any rate in Great Britain, and the decrease is especially noticeable in regard to rheumatic fever Much useful epidemiological information has been derived from American studies on the prevention and treatment of streptococcal pharyngitis, and in particular on the transmission of group-A streptococci [11], and some of the difficulties which may hinder attempts to eradicate epidemic strains of streptococci by the use of penicillin prophylaxis have recently been discussed by Frank [12] In the American army extensive bacteriological studies have been carried out in a streptococcal-disease-control programme, prompted chiefly by the high incidence in this population of rheumatic fever, following upper respiratory infections with group-A streptococci This incidence—about 3 per 100 streptococcal infections [13] is considerably higher than would be expected in, say, British schoolchildren similarly convalescent Holmes and Williams [14] at the Streptococcal Reference Laboratory, Colindale, have made a valuable long-term investigation of streptococcal disease in a large residential home for children

These workers studied 300–500 children living in a large Dr Barnardo's Home for thirty months, giving a total of about 12,500 child-months During this period 473 sore throats were observed, of which 60% were streptococcal (group A) The overall attack-rate (1 9 streptococcal throat infections per 100 children per month) was very similar to that reported by Dingle et al [15] in a study of American families living at home (1 2 per 100 person-months), but the incidence of a streptococcal sore throat in the children increased with age, "of the illnesses diagnosed as 'sore throat' the proportion yielding streptococci increased from about 34% in the 1–2-year-old group to about 74% in the children over 10 years old" *The influence of tonsillectomy on severity of streptococcal* infections was found to be negligible Most previous workers found a lower *throat* carriage-rate in tonsillectomised convalescent children than in others, and in previous work Holmes and Williams [16] found that this applied to both the throat and the nose carrier state, but in this latest survey they found that, while throat carrier-rates in convalescence decreased more rapidly when tonsils were out than when tonsils were in, the *nasal* carriage-rate was much higher in the tonsillectomised children both on admission and during convalescence This is a puzzling point, which is related to the second part of the survey

Here an attempt was made to define the potential sources of infection among the incubating, the convalescent, and healthy carriers, classified as nasal or throat type No similar study has been reported, and Holmes and Williams have devised a simple objective way of relating cases of sore throat to their recognised infected contacts They were able to relate 94 out of 205 sore throats to their probable or possible contacts, of these two-thirds were heavy nasal carriers of streptococci, and the remainder about equally light nasal or throat-only carriers This confirms the importance attached by Hamburger et al [17] to nasal carriers as sources of infection Holmes and Williams point out, however, that the importance of *healthy* carriers may have been overstressed, since both persons incubating streptococcal disease and convalescent carriers could also reasonably be incriminated as sources of infection, the numbers in each category equalling those of healthy carriers responsible for spread No cases of rheumatic fever were observed among several hundred cases of streptococcal illness, nor was acute glomerulonephritis found despite 49 cases of infection with type-12 streptococcus It looks as if the nature of streptococcal disease is undergoing a slow change, or at any rate is showing widening variation, which studies like this one help to define We look forward to the concluding chapters of Holmes and Williams' saga

LONG-ACTING COUGH SUPPRESSANT

IT is often desirable to ensure the slow and steady release of an active drug from the gut The simplest way of doing this is to take the drug after food A recent valuable innovation is the use of capsules each containing the drug in the form of a large number of microspheres coated with a digestible wax in varying thicknesses [18] A new principle has now been employed—the integration of the active drug in an ion-exchanging-resin complex It is claimed that a drug given in this way is released from the resin at a slow and steady rate which is independent of the environmental pH and of enzyme activity [19] A preliminary report of a long-acting cough suppressant, in which dihydrocodeinone and the anti-histamine phenyltoloxamine are combined in a sulphonic resin complex, has been published [20] The evaluation of cough suppressants is not always easy, and perhaps greater objectivity in the conduct of the trial might have strengthened the author's case But the preliminary results do suggest that this is a useful new approach

ZIRCONIUM GRANULOMAS

LAST year we recorded [21] the appearance of a new and unique dermatological entity, first described by Rubin et al in Chicago [22] [23] This consisted of dusky reddish-brown discrete papules, 1–4 mm in diameter, which were closely set in the domes of the axillæ and more sparsely placed at the periphery Histologically there were granulomas in the corium, composed of epithelioid cells and Langhans giant cells surrounded by lymphocytes in typical tuberculoid pattern There was no delineation of tubercles of the sort seen in sarcoidosis, and no evidence of necrosis Foreign bodies could not be detected by polaroscopic examination The infiltrate lay along the course of blood-vessels It was noted that these novel lesions appeared after the use of deodorant sticks which contained sodium zirconium lactate in addition to the commonly used ingredients Rubin et al were uncertain of the cause of this granulomatous eruptions but thought that the linear distribution of the lesions suggested razor abrasions

Further cases were soon described, always arising after the use of a deodorant containing zirconium salts But zirconium seemed non-toxic,[24] and there were no recorded instances of its having proved harmful in industry In biopsy specimens from the axillary lesions no zirconium was found, even by such refined means as X-ray fluorescence and emission spectrometry [25] Many alternative causes were suggested, such as foreign-body reactions to the lipid vehicle of the deodorant stick [26] and inflammation as the result of extravasation of apocrine sweat [27]

Shelley and Hurley [28] have contributed a well-integrated review of 64 cases previously reported and 6 of their own They find the clinical signs as well as the histological changes in the dermis to be strictly uniform and diagnostic Most cases were in women, and most of them shaved their axillæ No one brand of deodorant stick was responsible The eruption might follow a solitary use of the "zirconium stick" or appear only after it had been used daily for months

Shelley and Hurley then conducted experiments to elucidate the role of zirconium They instructed 30 healthy male volunteers to rub a standard commercial stick deodorant, containing 5% zirconium, vigorously into their left axilla every morning for five minutes A zirconium-free but otherwise identical stick was rubbed daily into the right axilla for the same period Both axillæ were closely shaved every other day None of the men had previously used zirconium stick

deodorants The test period lasted ten weeks, biopsies were taken from both axillæ in every subject After a month 1 volunteer developed an eruption in the left axilla, which clinically and histologically was identical with the clinical cases of axillary granuloma Applications were stopped after eight weeks, and no treatment was given The confluent papules, lying linearly as if developed in a razor cut, slowly subsided over the subsequent five months The opposite axilla showed no clinical or microscopical changes In 3 other subjects there was a transitory inflammatory papular response, which was not granulomatous, in the left axilla There was no reaction in the opposite axilla of these 3 or in either axilla of the remaining 26 subjects The concentration of zirconium was then changed and hexachlorophene, perfume, and carbitol were omitted from the stick. 1 subject out of a further 20 showed typical granulomas when 10% sodium zirconium lactate in a plain sodium stearate soap vehicle was used The opposite axilla failed to produce granulomas after a ten-week test with a stick containing 0 5% zirconium Patch testing in the 2 who reacted to the zirconium stick, as well as in 20 controls, failed to give any reaction Intradermal testing of the 2 reactors showed a unique granulomatous response—in 1 case to a dilution of 1/10,000 and in the other to 1/1000 No similar reaction was seen in control subjects even with concentrations as high as 1/100 The granulomatous reaction is specific to the zirconium element, for zirconium chloride and zirconium nitrate produced identical lesions in the 2 reactors Injections of 1/1000 beryllium sulphate and colloidal silica failed to produce a response in any subject, and in the 2 hypersensitive subjects the use of aluminium stick deodorants led to no granulomatous reaction

From these exhaustive tests Shelley and Hurley concluded that the granulomas were the direct result of a specific allergic hypersensitivity to zirconium They proceeded to test their observations on 4 patients with typical deodorant granulomas in their axillæ In each case their responses were identical with those of the 2 hypersensitive volunteers

In the past a number of granulomas have been thought to be allergic in origin, but this is the first time that the introduction of extremely small amounts of a pure substance has produced an allergic epithelioid granuloma in man. It opens up an entirely new field of immunological response with granuloma production May the reaction in the Mitsuda and Kveim tests be due to traces of highly specific allergens contained in extracts from lepra bacilli and sarcoid tissue respectively? It may soon be possible to discover the antigenic substance in the tubercle bacillus responsible for the tuberculoid granulomas—though here the amount of material needed to produce the reaction is appreciable, whereas the amounts concerned in zirconium granulomas are too small to be detected by analysis The method might be applicable in the diagnosis of pneumoconiosis or the demonstration of specific hypersensitivity in patients with beryllium, silicate, or tattoo granulomas There is no theoretical reason to suppose that the dermis alone becomes sensitised The ultimate mechanism must surely be chemical, and it would be interesting to learn how zirconium affects enzyme reactions in the skin Shelley and Hurley's work may therefore be of wide significance, they suggest that the detection of minute quantities of specific sensitising agents may lead to the discovery of the cause of sarcoidal granulomatous diseases of hitherto unknown origin

In this country we are unlikely to see any of these axillary lesions, though some possible cases have been suspected here, because zirconium has already been withdrawn from use in deodorants The stimulus of Shelley and Hurley's neat investigation remains

OCULAR LESIONS IN ONCHOCERCIASIS

ONCHOCERCIASIS has come to be regarded as one of the major blinding affections It is said that in some villages in Nigeria and the Gold Coast a tenth of the inhabitants have lost their sight from this cause Onchocerciasis has been known for some sixty years, and ocular lesions, first reported from Guatemala in 1915, were stressed by Hisette in 1932 in a classical account of the affection as seen in the Belgian Congo

The anterior third of the corneal stroma and the anterior chamber are invaded by microfilariæ travelling over the conjunctiva or along the subconjunctival plane, the iris itself may become infiltrated, though apparently the lens is spared The living microfilariæ seem to be well tolerated, and it is not the toxin of the organism, but the decomposing dead organism, which produces the irritative reactions in the cornea and iris Considerable interest centres on the fundus lesions that have been recorded in onchocerciasis since they were described first by Hisette, and subsequently by Bryant in 1935 [1] and by Ridley in 1945 [2] These lesions take two forms, one simulating the non-specific inflammatory reaction seen in chorioretinitis and the other—described by Ridley as a "hypothetical combination of choroidal sclerosis with retinitis pigmentosa"—involving the macular area and the disc, which shows secondary optic atrophy

In the earlier accounts the ocular lesions were described as complications of longstanding and severe affections But from a recent symposium held by the Royal Society of Tropical Medicine and Hygiene [3] it is clear that slight conjunctivitis, and possibly slight corneal lesions, may be a pointing sign in even mild infections The corneal lesion consists of opacities usually most noticeable near the limbus, with a tendency to spread across the cornea into the interpalpebral area In severe cases these opacities can become confluent, and only exceptionally do they become vascularised The causal relationship between these corneal reactions and the microfilaria of onchocerciasis can be established by slit-lamp examination—as is stressed by Choyce [4] in his criticism of the view expressed by Rodger,[5] who doubted the specificity of onchocercal keratitis Choyce also remarks on the difficulty of regarding onchocerciasis as a blinding affection, since only exceptionally is there any substantial reduction of vision from these corneal lesions, though the occasional case of iritis with secondary glaucoma may run a severe course The fundus lesion, which has attracted so much attention, was observed by Ridley in 12 of his 51 cases at Funsi in the Northern region of the Gold Coast In the Cameroons Choyce saw the fundus lesion described by Ridley, but he does not believe that this is caused by onchocerciasis, if only because microfilariæ do not travel by either the blood-stream or the central nervous system Microfilariæ have apparently not been found in the retina, and the fundus lesion does not appear to have been observed in Central and South America, where onchocerciasis is also prevalent He regards the fundus lesions as examples of the different stages of the dominantly inherited generalised choroidal sclerosis described by Sorsby [6]

If this is correct, there is little to justify the growing reputation of onchocerciasis as a blinding affection.

Whether this disease is indeed a significant cause of blindness is unlikely to be decided by merely descriptive accounts of the lesions The epidemiologist and the geneticist have clear criteria for determining whether a particular lesion is infective or genetic in origin, and it should not prove particularly difficult to establish the nature of the fundus lesion associated with onchocerciasis

ANTIBODY-ANTIGEN REACTIONS OBSERVED BY FLUORESCENCE

All interested in the infections which befall man and animals have wanted to find out where the invading microorganisms are distributed in the host It is known that when the respiratory tract is infected the microorganism can be isolated from this situation, it is known that, as the patient recovers, antibodies are produced in areas far distant from the primary lesion, and it is believed that the areas producing the antibody must have been stimulated directly by the infecting agent or its products What tissues distant to the obviously infected site have been in contact with the agent? The most fruitful experiments designed to answer this and related questions have depended on the use of fluorescent-labelled antibody [1] [2] By this method the globulin fraction of a hyper-immune serum is conjugated with fluorescein isocyanate, this labelled antibody combines with the appropriate antigen, and this antigen-antibody reaction can be seen because of the fluorescence

Coons et al, using this method as a histochemical stain,[3] demonstrated the cellular distribution of pneumococcal polysaccharides injected into the mouse, the distribution of rickettsia of epidemic typhus fever and Rocky Mountain spotted fever injected into cotton rats, and the distribution of mumps virus injected into monkeys [4] In this work the labelled antigen was used for staining sections Moody et al [5] used immune labelled globulin to identify *Malleomyces pseudomallei* on films, as would be expected from knowledge of the close antigenic relationship between *M pseudomallei* and *M mallei*, serum made from one type stained both organisms This work has been extended by Thomason et al [6] to show the position of various antigens on organisms of the salmonella group They have shown that the Vi antigen of the typhoid bacillus may not be evenly distributed over the surface—a result that others had predicted from various agglutination tests They also showed that an antigen known to be present in loosely related salmonella showed itself in stained preparations as fluorescent dots round the periphery of the bacterial cell This technique has not been found satisfactory for demonstrating salmonella in fæcal smears,[7] but may be of value for demonstrating shigella [8] Similar tests have been used to distinguish between *Entamœba coli* and *Entamœba histolytica* [9] These experiments yielded additional evidence that the reaction between antigen and antibody is specific

Last year Hobson and Mann [10] labelled specific antisera prepared with organisms isolated from the rumen of calves, and found it possible to identify many organisms by mixing on a slide small amounts of rumen contents, buffered saline, and labelled antiserum, placing a cover slip on the preparation, and viewing Though it was possible to obtain results by direct microscopy, a better picture was obtained photographically These workers state that naturally occurring fluorescing materials were present in rumen contents and occasionally in objects which absorbed conjugated antiserum, but with experience it was possible to distinguish these from the specific organisms both by morphology and by colour of the fluorescence

Whitaker et al [11] used labelled antibody to investigate fæces which had been collected from an outbreak of infantile gastroenteritis due to *Escherichia coli* 0 127 Films on slides were made from fæces, rectal swab, and bacterial cultures, these were stained with labelled antiglobulin, and a photograph was taken It was found that all fæces positive by routine bacteriological test were positive by the new technique In addition 61 specimens from cases reported as negative were tested and 39 were found to be positive by fluorescence, all these cases had been treated with neomycin, and it was suggested that the fluorescence showed the presence of organisms killed by the antibiotic

Globulin-fluorescein and globulin-rodamine conjugates have been used in the investigation of carcinogenesis [12] and the identification of tumour cells [13] Normal tissues react with globulin prepared both from the homologous species and that prepared from many different animal species, malignant tumour cells show no reaction This effect, which is non-specific, is believed to be due to physicochemical characteristics of globulin, allowing interactions between globulin and normal tissues that probably differ fundamentally from antigen-antibody reactions already described

In the elucidation of bacteriological and allied problems labelled globulin gives an answer very similar to that obtained from specific antigen-antibody reactions brought about by other methods, and difficulties which arise in such reactions are likely to arise with the newer technique It is known that many bacterial antigens are to be found in widely differing species of organisms, and in some organic extracts—possibly plants Obviously a fluorescent body in mixed material such as fæces cannot yet be unhesitatingly accepted as diagnostic of a particular bacterium or virus Another difficulty is that labelled sera may impart fluorescence to tissues to which they are not known to be related Such non-specific reactions may be reduced by absorbing the serum with minced kidney, and it might be necessary to absorb serum with human tissue if the serum were to be used for the diagnosis of human material By present technique the fluorescent method is time-consuming and unlikely to give a reliable answer more quickly than the conventional methods, but simpler techniques will no doubt be introduced, and this new method may eventually prove of value to the routine bacteriologist The staining of tissues with labelled normal globulin may become a valued method for the differentiation of malignant cells

POSTMATURITY

A J WRIGLEY
MD Lond, FRCS, FRCOG
OBSTETRIC PHYSICIAN, ST THOMAS'S HOSPITAL, LONDON, S E 1

THE nature and management of "postmaturity" has always been uncertain and difficult (I use inverted commas because the term has a different meaning to different people) Until very recent years the student and the practitioner have had little or (perhaps better) no guidance on it

As Ballantyne and Browne said in 1922, the problem was as old as the hills But now that childbirth has become progressively safer, what was formerly a minor trouble has gained in relative importance

Over the past fifty years three distinct policies seem to have been evolved, and each still has its adherents The original policy (A)—laissez-faire, or leave it to Nature—was based partly on clinical experience but partly on lack of understanding Dissatisfaction with this plan was followed by policy B—induction of labour *as a routine* so as to avoid the mechanical difficulties that may accompany birth of a large "postmature" baby The argument used was that it is better to induce labour unnecessarily many times than to run risks unnecessarily in a few cases At the moment, however, support for this policy seems to be on the wane, and the dispute lies for the most part between believers in policy A and those who accept the latest suggestion—namely, that the real danger lies in placental insufficiency or inefficiency—and accordingly act upon policy C

Two statements made some years ago seem to me to epitomise the problem Reynolds (1938) said

> "Postmaturity has peculiar difficulties as a subject for discussion, since we have at present no definition of what we mean Fœtal development, well above the average as regards size, weight, ossification, &c, is not necessarily a result of prolonged gestation, just as immaturity is not synonymous with prematurity"

Similarly, in America, Adair (1940)

> "There are individuals who persistently delay in the natural onset of labour, each pregnancy being of longer duration than the average normal, the fœtal size appearing to have no bearing on the phenomenon The fœtus may be oversize, of normal or below normal weight"

Any department of obstetrics can easily produce evidence that a large healthy baby can be born before the calculated expected date, and that one of normal weight or less may arrive in a perfectly healthy state much later

"The Exact Date"

Of course there is no exact time for gestation Indeed, it is a reflection on current teaching and intelligence that the statement is necessary at all For is there an "exact" height or an "exact" weight, or a uniform or "exact" rate of urinary secretion, gastric digestion, or (for that matter) cerebration? Why, therefore, should there be an "exact time for gestation"? Naturally, there should be a recognised *average* time for gestation, but in its calculation there must be as many variants on one side of the line as on the other, and most of these variants must be physiological and not pathological Hence no woman in her pregnancy can be given an exact date for the onset of labour, and any policy must be wrong if it involves routine interference with all pregnancies prolonged beyond a calculated period If there is no "exact date", management of the condition must vary from patient to patient

The Three Policies Examined

At this point, therefore, the road divides Those who insist on some inflexible rule need read no further The following comments on the three policies are made only to those who can agree that a precise routine is impossible

Policy A—leaving the onset of labour to Nature—has certainly much to commend it It allows the obstetrician a relatively easy and peaceful life The anxieties of the patient and her relatives can usually be allayed by pleasant platitudes or by citing the experience of many others who faced a similar predicament Every woman is likely to be familiar with the vagaries of an oven, and indeed this homely comparison should not be dismissed too readily as foolish and misleading All who have practised obstetrics will have met, as Adair suggested, many instances of women whose babies, of average weight and development at birth, consistently arrived either before or after the calculated expected date What is overlooked by those who follow rigidly the plan of laissez-faire is that variations from the normal are not extremely rare and can often be detected by clinical observation Such variables include the age of the woman and the state of her general health, pre-eclamptic toxæmia (even in the mildest degree), her physical structure and that of the bony pelvis, and the estimated size and maturity of the fœtus Strict adherence to policy A cannot be justified in the light of present-day knowledge, slight though this is

Policy B postulates that after a woman passes the date when labour is expected there is a steadily increasing risk that the fœtus will become unduly large and hence that its delivery may be difficult or dangerous This risk, I agree, is real, but it certainly does not justify a policy of *routine* termination of pregnancy *x* days after the "exact" day

We are nowadays told, on apparently incontrovertible evidence, that one can forecast accurately whether the fœtal head will pass through the bony birth-canal, and, if so, whether it will do so easily or with difficulty, but those who say this do not so much as hint that similar methods of observation can be applied to the "postmature" fœtus If it is possible to diagnose minor degrees of disproportion before the "exact" calculated date, it must also be possible to do so when this day has passed Either all efforts in this direction are valueless or they are valuable If they are valueless, then by all means accept policy B, but if they are valuable a routine induction of labour to avoid disproportion is unjustified The argument is absolute

In actual fact, the fœtus may be unduly large *before* the "exact" date, either fortuitously or because the mother has diabetes Fœtal size may also be influenced by rhesus incompatibility or by congenital abnormality Policy B does not take account of these possibilities Nor does it take account of women whose pregnancy seems to be consistently prolonged over the calculated 280 days, or of the fact that routine termination of pregnancy is bound to result in some premature births Its advocates forget that induction of labour, as a deviation from the normal, *must* have an incidence of morbidity Undoubtedly there are advantages in policy B, but its adoption *as a routine* cannot be correct

Policy C, in principle, is much the same as policy B—substituting the pathological bogy of "placental insufficiency " for the anatomical bogy of the large postmature fœtus Nobody will dispute that placental insufficiency occurs and is highly dangerous to the fœtus, and it is likely to be worst in women who have passed their expected date of delivery Accordingly routine induction of labour is recommended at some stated time—about which (very naturally) there seems to be no agreement—after the calculated " exact " date This policy, however, appears even more illogical than policy B, for, whereas some attempt at least can be made to assess the size of the fœtus in utero, at present there are no means whatever of assessing placental efficiency Figures have been produced to show that adoption of policy C has been followed by improvement in perinatal mortality, but the extent of the improvement must be compared to an improvement on a national basis, and perhaps the improvement in any particular department or centre may have been from " not so good " to " good " rather than (as is implied) from " good " to " very good "

We do, of course, know something about the circumstances likely to impair placental efficiency Thus Baird (1957) has shown that, like other physiological processes, it is more likely to fail in women, especially primigravidæ, whose pregnancy occurs toward the end of the child-bearing period, and there is wide appreciation of the almost inevitable impairment of placental function in pre-eclamptic toxæmia (however mild), hypertension, or diabetes But Rooth and Sjostedt (1957) in Sweden, and later Bancroft-Livingston and Neill (1957) in Belfast, have failed to confirm the very foundations on which placental insufficiency has been related to postmaturity These two sets of workers go as far as to advise that the supposed association between the two conditions be abandoned, for independently they had been unable to confirm the findings of Walker, Turnbull, and others of a diminution of oxygen-saturation in the cord blood with increasing gestation Be this as it may, there is no justification for the adoption of any routine of management, as advocated in policy C

Suggested Management of Postmaturity

" Postmaturity "—i e , the prolongation of pregnancy beyond the calculated (exact) date—is important because it is so common Some invaluable clinical facts are available for its management, but very few people seem to try to take all of them into consideration

1 In the first place, policy A is dead There is no place at all for complete neglect, no matter how often Nature appears to be successful

2 Next, it must be accepted that there is no such thing as an " exact " duration of pregnancy The arbitrary calculated date is useful and necessary, and in the woman who is being watched because of mild pre-eclamptic toxæmia or hypertension it may be of vital importance In such cases the pregnancy must be terminated

3 If the fœtus is large—as may happen either in health or through disease—appropriate action should be taken at the appropriate time Excessive size may be suspected by clinical observation either before, at, or after the calculated " exact " date

The suggestion has been made (Wrigley 1946) that, though an unusual increase in the size of the fœtus can be suspected by most observers, additional help would sometimes be obtained by noting the changing relationship between the bulk of the fœtus and the amount of the liquor amnii With increasing maturity the cavity of the uterus appears to be occupied almost wholly by the fœtus But it was emphasised that such findings could only be assessed with any accuracy if each patient was examined on each occasion by the same pair of hands—which is seldom done in the existing clinic or mass examination system With increasing maturity there is increasing muscle tone in the fœtus, and its appreciation may be helpful Mistakes are inevitable, for occasionally a small baby is truly postmature, and a large baby can equally well exhibit all the characteristics of prematurity

This suggestion, when first made, was criticised as esoteric, which was hardly just

4 As term approaches, every effort must be made to try to decide the " maturity " of the fœtus, but each case must be judged independently If at the expected date of confinement the patient appears in perfect health and the fœtus appears to be *small*, I would recommend that the case should be watched—but watched by the same person I would make an exception for the elderly primigravida, for whom labour should be induced

If at the expected date of confinement the size of the fœtus seems to be *normal*, the case can be watched again, but probably not for so long In reaching a decision, consideration would be given to factors such as the woman's age and parity, her height and build, and the shape and structure of her pelvis

If at term the fœtus appears without doubt to be *large*, and therefore almost certainly " mature ", or even postmature, labour should be induced

5 Such a policy avoids routine, and in consequence much unnecessary induction of labour It makes use of knowledge that is readily obtainable It takes into account the vital importance and influence of such diseases as pre-eclampsia, hypertension, diabetes, and rhesus incompatibility, and of the variable efficiency of the physiology of gestation in the later years of the childbearing period

Most important is an individual assessment of each case—individual in that every patient who passes her calculated date of confinement is observed by the same obstetrician

The adoption of the plan just outlined results in very few patients being induced for " postmaturity " During the years 1956–57, the obstetrical department at St. Thomas's Hospital delivered 1600 babies with a perinatal mortality of 34 5 per 1000 No fœtal perinatal death in this series was due to intracranial injury

REGIONAL DISTRIBUTION OF S H M O s

A CORRESPONDENT in our issue of May 17 (p 1071) asked whether the number of senior hospital-medical officers in each hospital region was known We are indebted to the Ministry of Health for providing the following figures (for various reasons, it is hard to state precise numbers, so round figures only are given)

Regional hospital board	*Whole-time equivalents at Dec 31, 1956*		*Actual number of S H M O s employed at Sept 1957 (full-time and part-time)*
Newcastle	90		140
Leeds	100		120
Sheffield	120		150
East Anglian	30		60
N W Metropolitan	140	580	1120
N E Metropolitan	110		
S E Metropolitan	120		
S W Metropolitan	210		
Oxford	60		120
South Western	110		160
Welsh	110		160
Birmingham	110		180
Manchester	120		200
Liverpool	70		110

It is important to note that the second column (totals for S H M O s in each region) includes those employed by boards of governors of teaching hospitals in each region, whereas the "whole-time equivalents" in the first column are for regional boards only The whole-time-equivalent figures for regional-board consultants were given in our issue of April 26 (p 907)

Greater Medical Profession

MEDICINE AND SPEECH THERAPY

MURIEL MORLEY
M Sc Durh, F C S T

DONALD COURT
M D Birm, F R C P

From the Department of Child Health, King's College, and the Royal Victoria Infirmary, Newcastle upon Tyne

UNTIL not very long ago the doctor practised virtually by himself Today he needs, and increasingly accepts, the help of many colleagues trained in disciplines different from his own Nurses, scientists, therapists, and technicians will all be necessary at some time for the proper understanding and treatment of patients

This multiplication of the techniques and the people involved in the care of the sick naturally complicates professional relationships The doctor finds himself to his surprise, and not always to his liking, the conductor of an orchestra in which many of the instruments are new and unfamiliar How should he respond to these new demands upon his patience and leadership? In an address to the Manchester Medical Society two years ago, T F Fox[1] said that the aim should be to create a "greater medical profession" in which everyone works to professional standards and experiences mutual professional respect Others, however, have advocated a subsidiary role for such colleagues and have encouraged them to accept registration as medical auxiliaries We have been thinking and working our way through this problem in relation to speech therapy, and we offer our experience as one way in which Dr Fox's general counsel is being applied

---

[1] Fox, T F *Lancet*, 1956, ii, 779

This account also seems necessary since certain critical letters[2] suggest that medical ignorance of the nature of speech therapy and the work of speech therapists is more widespread than we had supposed

Concise definitions are always difficult, but if we regard a doctor as one who, when invited, cares for the sick and advises the well, we might accept the definition of a speech therapist as "one who cares for speech"[3] Her function is "to assist the person with a speech disorder to achieve speech which is intelligible, adequate for the life he leads, and without abnormality which might attract attention"[4]

Up to the present some 1000 therapists have qualified in this country, and approximately 70 are working overseas For three years they study phonetics, normal voice and speech, speech pathology and therapeutics, and enough anatomy, physiology, neurology, audiology, psychology, and psychopathology to start their rational understanding of speech development and speech disorders After this training in a recognised school of speech therapy and the passing of a professional examination they become licentiates of the College of Speech Therapists (L C S T) This college, set up in 1945, is the recognised qualifying body in speech therapy having authority to grant diplomas and develop professional registration in this country Speech therapists are therefore a profession in Dr Fox's sense of the term, since they "share a body of knowledge which they try to increase and transmit to new entrants, and a code of ethics, a set of standards which they try to follow in their work"

At present there are some 700 speech therapists in active practice in this country unevenly distributed between education and medicine A quarter are working in hospitals and three-quarters in relation to local education authorities

SPEECH THERAPISTS' CONTRIBUTION

What are they contributing to the community? First and foremost they are treating a wide range of speech disorders, in both children and adults, with practical awareness of the needs of those whose usefulness in the community is limited through a speech disability When we remember that at least 3% of all schoolchildren have a substantial disorder of speech, and when we list the disorders they present—dyslalia, dysarthria, articulatory apraxia, stammering, speech disturbances with deafness or with structural defects such as cleft palate, and other associated defects in the language field such as specific reading, spelling, and writing defects—the scope of the therapist's work is plain to see To the small speech-therapy unit of our own teaching hospital 307 patients were referred last year, 254 being children and 53 adults During the year, 329 were discharged with improved or adequate speech, the total number of attendances made by patients being 3547 But speech is no marginal activity for the growing child or the responsible adult, and speech therapy, by assisting them to achieve effective speech, often relieves associated personal and family anxiety and assists development of the whole personality It is not irrelevant at this point to compare this socially useful function with the reward that society offers in return The commencing salary of a speech therapist is £455 and the maximum possible for the head of a department is £815

NEEDS OF THE YOUNG PROFESSION

The treatment and study of speech disorders has developed widely in many countries in the last thirty years Speech therapy is therefore a young profession and is sensible of its immaturity What are its needs—in its own life and organisation—at the present time?

The central need is for more intensive inquiry into the basis of speech and the real nature of the defective development or breakdown which confronts us in the speech disorders While accepting research as one of the primary functions of universities, we would not advocate the immediate development of independent university departments of speech Such departments already exist in many universities in the United States, but it would be difficult and undesirable in this country to achieve them in one stage There must first be a small but sufficient number of speech therapists, with high technical ability and with academic training and judgment, to work in—and eventually lead—a limited number of university departments The necessary steps to train and use such therapists should be taken now, and we understand that at least two British universities are considering this approach

In Newcastle we have so far followed the pragmatic approach For the past ten years an experienced speech therapist, a neurologist, a pædiatrician, and an educational psychologist have studied the natural history and attempted a rational classification of developmental speech disorders The speech therapist is also a lecturer in the university department of education This association of people concerned in everyday treatment and speech inquiry has now reached the point where formal recognition by the university could be rationally considered The university subdepartment of speech which followed such recognition might find its first home in Medicine, in Psychology, or in Education Whatever the parent department, it would need working relationships with pædiatrics, otology, neurology, psychiatry, neurological surgery, and plastic surgery It would have a threefold charge—to continue and extend research, to offer graduate training to a limited number of selected teachers and speech therapists, and to work towards an undergraduate degree course in which speech was the principal subject

RELATION TO MEDICAL PRACTICE

We have let our hopes and ideas stretch out into the future What are the needs of speech therapy in relation to everyday medical practice?

In many cases working relationships between doctors and speech therapists do not exist at all, and must be created In others the doctor, though at hand, is ignorant of, or uninterested in, speech disorders and unaware of what the speech therapist has to offer No-one can do good work in continuing isolation, and there should always be a doctor, in hospital or in the school service, who is the committed colleague of the speech therapist—available for regular consultation and engaged in common inquiry

This will not be easily or rapidly achieved Doctors came before speech therapists, and to most doctors in family and hospital practice speech disorders seem a mere drop in the ocean of real and imaginary sickness which is their unending concern And since these disorders are never fatal, and the social disability they cause may escape the doctor's notice, his interest is not easily aroused Speech therapists, too, because of their isolation may sometimes be tempted to usurp the functions of the doctor and offer advice to the patient which is beyond their scope The language of medicine, with its powerful significance for the patient, may at times seem temptingly simple to those confined to a single and necessarily limited part of the field Yet the relationship must be one between professional colleagues, and to regard the speech therapist as a medical auxiliary is unreal and unworthy She is a specialist in her own field, and should be responsible for the diagnosis of the speech disorder and for deciding the type and length of treatment which will be most appropriate

---

[2] *Brit Med J*, 1956, ii, 768, 884, 1000, 1058, 1118

[3] Wilkins, J L Report of Conference on Speech Therapy, p 3 London, 1948

[4] Morley, M E *Med Pr* Nov 1953, 230, 448

In the teaching hospital in Newcastle, after long experience and careful consideration, speech therapy has been established as a separate unit The senior speech therapist has become the therapist in charge, and medical responsibility is in the hands of five specialists who are available for consultation by the speech therapist and by the hospital administration and are responsible to the board of governors of the hospital The specialists are the senior consultants in neurology, otology, and plastic surgery, and the heads of the departments of child health and psychological medicine They are essentially the people who have shared in the practice and study of the subject in the past ten years, and we feel that it is best for inquiry, in this way, to precede organisation

The majority of speech therapists, however, are working with local education authorities, and they should find natural allies within the school health service Once again the problem is lack of enough doctors with sufficient understanding to work effectively with the speech therapist The teaching hospitals at present, and the university speech departments of the future, have an important and largely unfulfilled responsibility to present the subject to medical students, teachers, school medical officers, and family doctors

We are not blind to the time and effort and patience which the building of more effective relationships between doctors and speech therapists will require But neither are we in doubt about the need In this world of newspapers, cinemas, theatres, radio, television, and innumerable committees, felicity of language and excellence of diction are more necessary and more sought after than ever Education, medicine and speech therapy share the main responsibility here, and they would do well to face it in a more thorough way than has been attempted so far in this country

Yet in conclusion we would keep a sense of proportion This is a difficult subject and we are only at the beginning of understanding The problems of sincere and effective communication between men and nations are broader than speech We must be honest and precise about our ignorance We still have to find practical ways of developing research and increasing the numbers of speech therapists capable of university standards and responsibility On the other hand, we must avoid the monotonous multiplication of speech-therapy services for the sake of administrative tidiness or to enhance professional prestige Finally we recognise "that every addition to the number and variety of people concerned with a given patient increases the strain on the judgment and resolution of the person responsible for the patient's welfare" That person remains the doctor, and "to hold their own in the Greater Medical Profession doctors will need to be very good doctors indeed"[1]

The Widdicombe File

XLVI MERIT AND MONEY

MY DEAR WHIDDON,

WHILE you and the others were talking of Merit Awards, I having neither merit nor expectations let my thoughts stray to the size of my electricity bill and how to fish the Herring-guts pool in high water But what I overheard of your conversation returned to me on the way home, and I am bound to say that all of you were barking up the wrong tree

There is a sum of money put aside to reward merit among the consultants So long as you accept this idea (and would not prefer the fund to be used to reduce the National Debt) the argument is limited to the way in which it should be distributed If you are an egalitarian you will say that merit is indivisible and that everyone should get an equal cut of the cake—like Prime Ministers or postmen Alas for the vanities of this sordid world, but some of our colleagues are convinced that they have more than their share of merit and are quite agreeable to some financial recognition of their superior talents Mere titles of honour—like the F R C P or Hero of the World Medical Struggle against Scabies—are not enough How then shall we select the meritorious?

Length of service alone has, I believe, some advocates, and, seeing that a grey head is reassuring, there is a lot to be said for it provided that we forget the word "merit" It would remove every imputation of favouritism, prejudice, and fancy and might dissuade those, deepest in the red from migration to Botany Bay Or the consultants might be paid "by degrees" For example, if a D L O or D C H is valued at £*x* per annum, then an M D would be worth £2*x*, and the F R C S £3*x* an F.R S would be worth at least £5*x*, honorary degrees score double, and a Nobel prize would give game, set, and match This scheme would improve the finances of the examining bodies, but I foresee one or two—perhaps minor—disadvantages A third alternative is to estimate worth by its contributions to original knowledge, but then, I fear, the glittering prizes would fall not to sharp swords (or scalpels) but to chest physicians or even biochemists

I thought I knew the evils of the present system of selection, but, to judge from what I overheard, simony and nepotism are the least of the crimes committed by the selectors, who are, moreover, so deranged as to be unfit to judge the class for stump-rooted carrots at our flower show Maybe this is all true, but I have a suspicion that what worries your colleagues is that (*a*) they have no award, (*b*) they do not know how or why A N Other got his award, (*c*) it would be nice to know if they would get an award later I sympathise with you on every score, but so long as the distribution of these gilded baubles depends upon intangible—perhaps indiscernible—merit, so long will 60% of consultants tell us that the cards were stacked before the game began

I have no doubt that we must start again Who are those doctors whom we all hold in the highest honour? Of this there is no doubt They are those—not of necessity those with most degrees or the largest practices or the most clubbable—whom we others, as husbands and fathers, summon to the bedside of our ailing wives and children This has always seemed to me the highest honour which any doctor can pay to another, and the Georgian cream-jug (or the dozen of champagne) is but a poor token of our trust and gratitude It is these Physicians and Surgeons in Ordinary to their unhappy colleagues who deserve all the rewards for merit which are available, and I suggest that the fee for a domiciliary visit to a doctor's family should be a thumping one—say 50 or 100 guineas or whatever figure the fund will allow The cream-jug will give some permanence to a reward which, thanks to the Commissioners of Inland Revenue, will be rather evanescent

It will be hard on the venereologists? Well, the present scheme has not pleased everyone

Yours sincerely,
Harry Hawke

Public Health

Occupation and Mental Illness

In a Supplement on Mental Health,[1] the Registrar General relates mental illness to occupation Admissions to mental hospitals in 1952 and 1953 are analysed to show the diagnosis on admission and the social class of the patient (I professional, II managerial, III skilled, IV semi-skilled, V unskilled) In addition, first admissions of men aged 20 and over in the five years 1949–53 have been specially analysed in three groups of diagnoses and a hundred occupation groups

Among males aged 20 and over, admission-rates in 1953 for schizophrenia, manic-depressive reaction, and psychoneuroses were all highest for patients in occupations assigned to social class V For disorders of behaviour, character, and intelligence classes I and V had rates considerably higher than the other classes Estimated first-admission rates for schizophrenia increased from 88 per million population in class I to 383 in class V, for manic-depressive reaction rates were 235 in class I and 213 in class II, increasing to 392 in class V Analysis within the classes suggests that certain occupational groups are associated with first-admission rates above the average, but such association is less clear in manic-depressive reaction than in schizophrenia In general

"Adverse rates appear to be connected with a high standard of education, with clerical work, domestic work, branches of the catering industry and with labouring Why this should be so is open to speculation and it is difficult to separate cause and effect

"How far the actual work and how far the general living conditions which certain types of industry involve are connected with mental health is uncertain Detailed ecological studies are required, taking in the worker's whole environment, and a start might possibly be made among those groups which have been shown to have exceptionally high or low admission rates"

Smallpox

A 53-year-old man died of smallpox in New Ferry Isolation Hospital on May 20 He was the man mentioned in our note last week (p 1135) His wife's illness has been mild Up to Tuesday of this week no further cases had been reported, and it is hoped that the outbreak may have been curtailed

In England Now

A Running Commentary by Peripatetic Correspondents

The Siamese cat was, I thought, a brilliant piece of therapy—much better than the hemicolectomy I had undertaken for the removal of Mrs A's cæcal growth, which her Alsatian had brought to our attention Mrs A, in her late 60s, lived alone but for the Alsatian whom she adored, in fact affection started the sequence of events, for the dog jumped up to greet her and the blow of his paws upon her abdomen suddenly caused her to feel faint She lay down, and a contrite dog, sensing something amiss and anxious to make amends, went to lick his mistress's face, once more his weight fell upon her abdomen Mrs A came into hospital and her neighbour ordered the dog to be shot

The almoner looked at me askance must it be a Siamese, wouldn't any cat do? I explained the particular merit of a Siamese, that it more than any other cat would recognise one person only as its mistress, would love its mistress and her alone, and would cause no accidents by boisterousness The almoner grasped the idea and in no time, so it seemed, had succeeded, so Mrs A was able to return home with a companion My brainwave exceeded my best hopes The singleness of that cat's affections would have done credit to Penelope, Mrs A was always greeted with a furry rub across her legs not so her visitors At the sound of approaching footsteps that cat would leap to the top of a cupboard in the hall and then pounce with full fury on an unsuspecting head It had extraordinary virility, being unable to come to grips with the inmates of a neighbour's aviary it sat outside the wire and gazed with such malignant intent that one by one the priceless birds fell with terror to the ground After six had died their owner registered a strong complaint, but on hearing how Mrs A came by her cat was filled with remorse, and the ensuing friendship between Mrs A and her neighbour must really be put to the cat's credit

There's no doubt that the idea was a masterstroke (and I recall with pride and pleasure how I used to draw the attention of the students to this, the most important part of the patient's treatment) But I am growing a little uneasy Mrs A now has hepatic metastases and must soon be admitted to a home Who will look after the cat?

* * *

I was just about to give the injection for the I V P when I noticed that the iodine skin test which the patient had been asked to apply the previous afternoon looked peculiarly yellow The simple instructions delivered with the iodine ampoule had perhaps not been simple enough, and the patient had taken the ampoule, if not the instructions, untouched to his family doctor The doctor advised him never to use iodine as it produced such reactions, and painted the forearm with acriflavine

* * *

Our senior partner took a Bentley into partnership long before such a desirable symbiosis became an advertising gimmick General practice must have been a most rewarding experience in those far-off happy times No shouting over the rhonchi, no flutter of hire-purchase deeds, none of the contorted humiliation of the new poor as we squeeze into our little pressed-steel boxes While the expense accounts and industrial assets glide by, we sigh for the golden years All but the senior partner He refuses to sigh for anyone The Bentley's coachwork, like his own, may look a bit battered, and her lines betray the years But her works, like his own, are as big-hearted as ever You might be tempted to think that they are dead but they won't lie down Not a bit of it Neither of them is ready for the scrapyard yet They've done a mere fifty thousand since they each had a rebore Just fill them up, point them in the right direction, and watch for the cloud of dust Proud they are of their vintage maybe a little too proud That was their undoing The old boy wanted a few days' fishing in Scotland, so my wife and I went with him, a gaff and a catheter in the boot All went well until we were dawdling at 55 over the Rannoch Moor then a Jaguar had the nerve to overtake

---

[1] The Registrar General's Statistical Review of England and Wales for the two years 1952–53 supplement on Mental Health H M Stationery Office Pp 208 1958 11s 6d

The senior partner's hackles rose up. A nicely polished brogue shot down. My wife gripped the edge of her seat. I felt the kick of adrenaline. The Bent roared with delight down the narrow road, over the concrete bridge, and took the Jag offguard on a sweeping curve. The old boy's triumphant blast on the horn was more expressive than any manual gesture a lesser mortal might have been tempted to make through the rear window. But the effect was precisely the same. The Jaguar opened up and sat tight on our tail. Glencoe came in sight. I thought of the massacre. Ballachulish ferry seemed so far and yet so near as time and the heather flashed by. The Jag was pressing us hard as we thundered down the glen. The old man was pressing the Bentley, and just about holding his own, when centrifugal force took over from gravity. The road swung away to starboard, and we were airborne. The senior partner's remarks were irreverently unsuitable for our flight. However, the Scottish bogs are resilient, and never perturbed to absorb a couple of tons of kinetic energy. We made a rather spectacular belly-landing, and that was that. By the time I had helped out the missus, old King Lear was striding over the blasted heath shaking his fist at the back of the Jaguar. His rivals were far more in need of shock treatment than he was. He saw the point, and came stumping back to the car. Old faithful never let him down. There in the cubbyhole was an intact bottle of Scotland's best. It was a jolly party that zig-zagged into Fort William. The partnership was unbroken. Someday we look like having a Bent of our own. My wife is the old boy's daughter.

* * *

The chief was doing his round one morning with the registrar, houseman, and firm in attendance when he came to a patient who was suffering from chronic nephritis. Picking up the chart at the bottom of the bed he noticed that for day after day the urine had been marked up "N.A.D." Turning to the clerk in charge of the case he said "I see that you're very keen, my boy, and have obviously been testing the urine every day. Tell me, what was the albumin content?" The clerk replied "I don't know, sir." On being asked whether there was any blood present he once more replied "I don't know, sir." This rather upset the chief, who once more looked at the chart, and, seeing column upon column of N.A.D.s, asked "Well, my boy, what *do* you mean by writing N.A.D.?" "Not a drop, sir."

* * *

The rugger type who nearly knocked over your peripatetic correspondent on the Holborn escalator last week is a pleasant soul, but an unpunctual one. He is often in a hurry. Having boxed a good deal, as well as playing rugby, his features appear hostile even when he is at his most amiable. While hurrying down the escalator he recognised instantly that the man he bumped was a psychiatrist. He also perceived that any action other than a hasty apology over his shoulder would lead to ten minutes' discussion on underground neurosis. This would have made him even later than he was already.

Many of us are prone to projection, and perhaps it is a conspicuous symptom in rush-hour psychopathology.

* * *

The patient from Chipping Sodbury had his cycle clips on. I saw on his treatment card that he had been performing on the static bicycle for the benefit of his knee and remarked that there was nothing like taking his exercises seriously. He blushed and apologised for not taking off the clips before he came in, but as he was a little late for his appointment he had come straight in and had not even had time to park his bike.

As I saw him later, starting on his long ride home, my mind went back a few years and many thousand miles to Mauritius, where I had once watched a group of women and children huddling under the wall outside the door of the X-ray department, seeking the little strip of shade that the eaves made in the high summer sunshine. Soon their turn would come to escape from the blistering midday glare into the cool interior for their general ultraviolet-light treatment.

Letters to the Editor

IODINE PROPHYLAXIS OF GOITRE

SIR,—In your issue of May 17 Dr. Greenwald criticises the proposal to iodise salt—on two grounds. First, that goitre in many parts of the world is diminishing in prevalence, and, secondly, that iodised salt is not without its possible dangers, supporting his thesis with 20 references to the literature dating from 1885.

The literature on goitre is so vast and often so conflicting that support can be found for almost any theory. Thus, as regards the evidence of recruits rejected because of goitre for military service in Switzerland, Eggenberger[1] declared at the Third International Conference that in the Swiss county of Appenzell the introduction of iodised salt was accompanied by a decrease in the incidence of goitre in recruits *from 7% to 0.1% in 16 years*. *More recently* Nicod[2] at *the* 1953 W.H.O. Conference on endemic goitre stated "Un seul canton reste refractaire a l'usage du sel iode, c'est celui d'Argovie et, fait interessant, c'est celui qui aujourd'hui reforme encore le plus de jeunes gens pour goitre." A comprehensive review of no less than 939 articles in the literature published this month provides much further information.[3]

The second contention can be answered more concisely. There is no accredited record of hyperthyroidism arising from the prophylactic use of iodised salt. There *are* reports of its occurrence following pharmacological doses of iodine, the so-called Jod-Basedow.[4]

However, Dr. Greenwald's scholarly researches are of more than historical value: they do help to show that the distribution of simple goitre may be related to the geography, geology, and dietary habits of a country. When the overall intake of iodine is low, the incidence of thyroid enlargement may well be determined by goitrogens which do not normally affect us, such as calcium.[5]

Dr. Greenwald's intransigence in opposing iodised salt can perhaps best be countered by the statement of an equally staunch supporter of iodine prophylaxis, Dr. Kimball.[6]

> "We have definitely proven that:
>
> "(1) Simple or endemic goitre is a deficiency disease and this deficiency is iodine in our food and drink. This iodine deficiency was caused primarily by geological conditions and has been made worse by our refinement of foods such as salt.
>
> "(2) The addition of an exceedingly small amount of iodine to our food in endemic goitre regions prevents goitre. The most practical method yet devised is iodised salt."

London, S.W.15. SELWYN TAYLOR.

THE FUTURE OF THE PUBLIC HEALTH LABORATORY SERVICE

SIR,—Your entertaining correspondence on this subject has not proved as stimulating as I had hoped, and the criticisms of pathologists-in-charge made by "London Bacteriologist" (April 26) and "Hospital Bacteriologist" (May 10) have fallen rather flat.

As a pathologist-in-charge whose entire bacteriology department is run by the Public Health Laboratory, I can assure all your correspondents that, with a little good will, cooperation on both sides, and a sense of humour, the system works excellently, and, what is important, to the satisfaction of my clinical colleagues.

Hospital Bacteriologist will no doubt be delighted to know that I would not dare, even if I so wished, to "inter-

TOTAL GASTRECTOMY FOR BENIGN PEPTIC ULCER

SIR,—I wish to comment on the conclusion drawn by Dr Balint and Mr Gummer in their paper of May 17

The statement that the operation of total gastrectomy "is justified in patients with obstinate anastomotic ulceration not arrested by adequate gastrectomy and vagotomy" requires modification Until recently "adequate vagotomy" implied only an ill-defined impression at the time of operation A test for completeness of vagal-nerve section at the time of operation has recently been described by Burge and Vane[1] Their experience with this test must raise doubts about any conclusions based on operative assessment of complete vagotomy

It would seem, therefore, that before the operation of total gastrectomy can be considered justified or advocated for adoption in the treatment of "pernicious ulcerators",[2] some method of testing for complete vagal-nerve section must be employed

SYMPTOMS AFTER CHOLECYSTECTOMY

SIR,—May we reply briefly to certain points raised by Mr Dudfield Rose (May 17) in his criticism of our article of May 3?

We failed to find any evidence of biliary dyskinesia in the series of patients we examined at periods of 1 to 7 years after cholecystectomy Mr Dudfield Rose suggests that our conclusions in this respect are unwarranted unless we carried out one or more of the following investigations serial cholecystography, per-operative manometry, and chronovolumetric estimation of bile Serial cholecystography was not part of the preoperative investigation in this series We believe the radiation exposure involved is unjustified Furthermore, the method requires visualisation of the gallbladder at cholecystography, so would have failed in 45% of our cases Much has been written on per-operative manometry, but we are not convinced that valid records of biliary pressure can be obtained in man under anæsthesia, even if premedication is omitted The third method, chronovolumetric estimation of bile, is admitted by Mr Dudfield Rose to be sometimes misleading

We found that only 7 patients (5%) had symptoms between operation and follow-up examination referable to the biliary tract All had organic lesions which adequately explained the symptoms stenosis of the sphincter of Oddi, pancreatitis, stone in the common bile-duct, and postoperative adhesions

All other patients with postcholecystectomy symptoms had extrabiliary lesions which we considered as the cause In view of the necessarily brief data we gave, we are surprised that Mr Dudfield Rose has been able to postulate that certain of these cases had hypotonic dyskinesia The following details of two of the cases cited by him are typical of all cases in this group, in that the symptoms do not originate in an autonomic imbalance in the biliary tract

Case 8—This woman has been completely relieved of her preoperative biliary pain and flatulent dyspepsia she now presents with lower abdominal discomfort and constipation A clinical suspicion of diverticulitis has been confirmed by barium-enema examination

Case 10—This woman has been similarly relieved of preoperative biliary pain and dyspepsia *her present symptoms are of classical* migraine with hemicrania followed by bilious vomiting, occurring at the time of menstruation

In both cases intravenous cholangiography has demonstrated a normal biliary tree

TREATMENT OF BREAST CANCER

SIR,—The paper from the Mayo Clinic[1] and your leading article of Feb 1 refer to a matter of great importance, and, coming from such sources, their conclusions must carry considerable weight

Several of your correspondents have already commented on the statistical aspects of the Mayo Clinic report, but some of the clinical implications should also be noted

McWhirter,[2] in the paper from which the Mayo Clinic workers take his survival figures to compare with theirs, clearly defines the "operable group" (for the radical operation) and confines his use of the term to the Manchester clinical stages I and II, excluding (*a*) all cases of locally advanced disease (i e, all cases showing "complete fixation of the primary tumour to the pectoral fascia or to the ribs, fixed nodes in the axilla, enlarged supraclavicular glands, or widespread involvement of the cutaneous lymphatics over the breast") and (*b*) those with distant metastases With this definition, I feel sure, the great majority of surgeons who practise the radical operation would agree, indeed some would define the operable group even more strictly

Unfortunately, as clinical staging of breast cancer is not used in the Mayo Clinic, accurate direct comparison of the two series is not possible However, unless the criteria of operability (for the radical operation) at the Mayo Clinic differ very considerably from those elsewhere, one must assume that their "operable" cases in the period 1941–47 consisted almost if not entirely of cases in stages I and II Crile[3] has already pointed out the similarity of the five-year-survival figures from the two centres on the basis of this assumption

On the other hand, if this assumption is incorrect, the Mayo Clinic series may contain a considerable number of cases of locally advanced disease (as defined above) If this is so, the five-year-survival *rate which is reported* suggests that the radical operation is being restricted too severely in other centres, and all surgeons dealing with mammary cancer will need to reconsider their criteria of operability In view of accumulated experience of the survival figures in such cases elsewhere, they are unlikely to do this unless the Mayo Clinic workers can produce figures giving the numbers of cases in the "operable" and the "locally advanced" groups (as defined above) in their series, with the corresponding survival-rates for each group

It is evident that until an international system of clinical staging is agreed upon and put into effect no accurate comparison between survival-rates at different centres can be made, and consequently the comparative value of different forms of treatment cannot be assessed It is for this reason particularly that the meeting of the International Cancer Congress in London in July, at which this matter is to be considered, is of such importance

Proceeding one step further, it would seem that the pathological grading of mammary cancer may well be of

TREATMENT OF OBESITY

SIR,—The letters by Dr Mullins (April 5) and Dr Badham (April 20) on the treatment of obesity completely ignore the psychosomatic aspects of the overweight patient.

It is easy to put a patient on a diet, give appetite-reducing pills, and get a considerable reduction in weight However, this weight is regained almost invariably once supervision is discontinued While treatment appears to have been a success, long-term follow-up reveals failure of such a therapeutic regimen The reason for this is that increased appetite is considered to be the basic cause of overweight, whereas in fact it is only a symptom of a particular patient's reaction to underlying psychological stress

Patients who overeat do so because of unsatisfied oral needs When they are unable to face their problems on an adult level they regress to the level of infancy Just as a baby turns to the breast for comfort when he is unhappy, so do obese people overeat during periods of stress Other manifestations of this regression to the oral phase are excessive smoking during periods of difficulty, nail-biting, and the chewing of gum and tobacco

Obese patients require psychotherapy, which should be devoted to helping them to express themselves and "getting off their chests" those things which are distressing them If this is done they will no longer find it necessary to regress and consequently to overeat

Central Islip State Hospital,
New York.

M G JACOBY.

TREATMENT OF ASTHMA AND HAYFEVER BY HYPNOSIS

SIR,—This correspondence is of great interest to those who work in the field of hypnosis

Some allergists hold that the allergic reaction is the only stimulus responsible for asthma, while others say that allergic disposition may be present in a patient but under normal conditions the allergy may be latent or mild and yield to conventional treatment. Under the stress of emotions, however, it can become chronic and disabling When this occurs it can again be eliminated by therapy of the emotional factors even though the skin-sensitivity tests remain the same

Herxheimer's experiments[1] with house dust showed that among the patients giving a positive skin reaction a high proportion did not give any bronchial reaction Conversely, some patients' skin reaction was negative but they had bronchial spasms In 1954 he again stated[2] "we have tested the skin responses of 300 patients with respiratory allergy and of 100 normal subjects, and have found their outcome in the same subject most variable Only in three out of 21 patients could we reproduce exactly the same result on two different occasions"

Bignall[3] says "Skin testing seldom aids in diagnosis and treatment It is generally more profitable to explore the patient's mind and his environment than the lungs, sinuses or hypersensitivity reactions

Since we take care of people and not just their diseases we cannot help dealing with their emotions The more knowledge the doctor possesses of the emotional factors in his patient's illness, the more capable will he be in dealing with him and his disease In the asthmatic, alteration of the psyche is the rule rather than the exception One physician quotes the case of a patient who is sensitive to ragweed pollen, but who, interestingly enough, does *not* have these attacks when his mother-in-law is out of town.

With my own asthmatic patients, Sally and Victor were sensitive to feathers Robert was sensitive not only to feathers but also to cats and birds Barbara was sensitive to chocolates while Brian could not tolerate onions or plums Mrs C could not eat pork, cheese, or eggs, while Theo could not stand dogs Tim was upset by dust and also got tight and wheezy when the weather was dull and damp (how do you skin-test for that?) Mrs B hates gas and smoke, so does Mrs P who works in a pub Mrs B cannot eat fish, potatoes, or milk pudding, while Mrs D cannot face milk, fish, cheese, or eggs

With repeated reassurance under hypnosis all these patients have become immune to their so-called asthma-producing allergies

London, W 1

A P MAGONET

CARDIAC SYNCOPE AFTER SWALLOWING

SIR,—In his report of a patient with cardiac syncope induced by swallowing, Dr James (April 12) has given a rather complete explanation of some of the factors that may have been responsible

He and your readers will find it of interest to review the case described[1] by Dr S Glatzer, of Brooklyn The patient, following digitalisation, began to experience syncope immediately after swallowing water It was demonstrated that carotid-sinus pressure induced a typical syncope Two days after the digitalis had been discontinued, neither deglutition nor carotid pressure could cause syncope

Dr Glatzer felt that the sequence of events in this patient could be attributed to increased sensitivity of the carotid sinus, accompanying digitalis toxicity He also pointed out that increased carotid-sinus sensitivity occurs in myocardial infarction

Thus, in Dr James' patient, the digitalis and the infarction were undoubtedly ætiological factors, and so possibly was the midœsophageal diverticulum, with the carotid sinus acting as mediator for the sensitising influences

Long Beach, California

GEORGE X. TRIMBLE

ALPHA TOCOPHEROL AND CONGENITAL ANOMALIES

SIR,—Mr E V Shute[2] claims to have demonstrated that the administration of alpha tocopherol to potential fathers prior to conception, in cases where a previous child with an anomaly had already been born, was effective in preventing further malformations If this were in fact the case, the study would be of very great importance It is unfortunate therefore that Mr Shute's conclusions are open to criticism

He concluded, on the basis of his previous experience, that the risk of a subsequent abnormal child, by his definition, in a family where one has already been born, is 1 in 7 In his experiment he gave alpha tocopherol to 17 such fathers prior to conception The 17 conceptions resulted in 15 normal children and 2 "anomalous infants" Professor Randal Cole concluded that the chance of getting 15 normals out of 17 in these families with an abnormal child was 1 in 500 This result was obtained, however, by reckoning in the index cases or propositi, who had drawn attention to the families in the first instance This is inadmissible. Mr Shute's own method is the correct one (reckoning the probability by taking account of all the siblings except the index cases) and his experience showed this to be 1 abnormal in 7 sibs, which conforms as nearly as possible to the findings in the cases where alpha tocopherol was given to the fathers

BRIAN H KIRMAN

GONADAL DYSGENESIS

SIR,—Dr Hubble (May 10) suggests that Lawson Wilkins' textbook[1] contains what is already an adequate account of the subject of the primary testicular disorders of the Klinefelter group I am sure Dr Wilkins would be the last person to make this claim on his own behalf (see his textbook, particularly the second paragraph on Primary Testicular Disorders, p 236, and the footnote on p 232) Knowledge in this field is advancing exceedingly rapidly In my own paper in your issue of May 3 I was concerned chiefly to present facts for instance, to describe testicular appearances in this condition before puberty, for remarkably little is known about these early cases, the analysis of the significance of these facts was necessarily brief The views of the Glasgow group interested in this subject, to which I belong, have been stated more fully elsewhere,[2] and will I hope clear up some of Dr Hubble's doubts

It is generally agreed by those working in this field that the whole subject of the nomenclature of testicular disorders in particular, and abnormalities of sexual development in general, needs a thorough overhaul, and I believe there is some hope of an international committee being set up in the near future to attack this problem

M A FERGUSON-SMITH

TETANUS AND IMMUNISATION POLICIES

SIR,—No-one would deny that it is ideal for children to be actively immunised against tetanus, not only to protect against tetanus but also to avert the danger of anaphylactic reactions due to A T S in the increasingly large proportion of the population who have received this injection

But it seems scarcely worth providing active immunisation against tetanus unless there is some way of telling in the future which child has, and which has not, been immunised Obviously, the easiest way is to tattoo in large letters on the child's body " Immunised against tetanus give booster, not A T S ", but this and any other tattooing policy is not going to be accepted by our patients—and who can blame them? Nor can identity discs, or cards to be carried in purse or wallet, be the answer They will be lost or left at home when most needed Nor is it any good relying on the patient's medical record card, even if every immunisation is conscientiously entered (and the vast majority are not) the record cards are available only at the doctor's surgery Ask the parents? I would estimate that half of them do not know for certain the diseases against which their children have been protected

What is the answer? It seems to me that the *only* possible answer is to have a national policy for immunisation In January my colleagues and I wrote a letter[3] drawing attention to the veritable state of confusion that exists over the whole policy of immunisation and put in a plea for a national policy The decision whether or not to immunise against tetanus, and if so whether to use single or combined vaccines, varies from one doctor to another, from one clinic to another, and from one county to another in a completely haphazard manner We must be free to treat and prescribe for our patients according to our own lights, but this excess of individuality is of benefit to no-one A national policy for immunisation would have to be worked out by some advisory body (for example, an M R C committee), but the addition of poliomyelitis to the already formidable list of routine immunisation procedures makes this a matter of urgency, A plan, as simple as possible and including tetanus toxoid, is needed, and the argument in favour of combined vaccines seems overwhelmingly strong

The only possible objection to a uniform national plan of immunisation is a national dislike of uniformity I confess to at least my fair share of this dislike, but in this particular instance it would seem a trivial objection against the urgent necessity for such a plan

Wantage,
Berks

I S L LOUDON

RECORDS OF IMMUNISATION

SIR,—We agree wholeheartedly with Dr Randall (May 3) that something could be done to issue permanent records to those people who have been or are being actively immunised

Here all casualties are actively immunised against tetanus, commencing six weeks after their injection of antitoxin or at once if they react to an intradermal test dose The course was originally aimed specially at agricultural and slaughter house workers, and allergic persons, but is now available to everyone

Cards have been printed specially to record these injections (thick yellow cards for the patient, and thinner white ones for filing) and an appointment system is used So far only about 5% of patients who have commenced the immunisation course are having to be sent for a second time and about 10% of those just commencing The proportion of patients who do not remember to bring their yellow cards with them at subsequent injections is even smaller

By having these standardised cards the course is open to anyone in the district who desires it, and the cooperation of the various works' doctors, general practitioners and the medical officers of health is being obtained, so that if any of them wish to immunise their patients they may do so, and after they notify us, we forward the patients' cards and add their names, &c , to our own records

Casualty Department,

P A GARDNER

Pharmacy Department,
North Lonsdale Hospital,
Barrow-in-Furness

A K McIVER

SIR,—I read with great interest the letter from Dr Thomas Scott (your issue of May 17) on the use of toxoid and A T S I think the points he makes should be emphasised up and down the country I think, however, it should be made clear to Dr Scott that it is extremely difficult in a busy casualty department for anyone to find out if patients have previously been immunised by means of toxoid

In the nine years since I took charge of this department not a single patient has ever volunteered that they have been immunised against tetanus I make a practice of inquiring from ex-Service candidates whether they have knowledge of immunisation against tetanus It is rare to get any satisfactory answer

I would suggest that in every case where immunisation has been carried out against tetanus, a suitable card should be provided for the patient in which it states unequivocally that this has been carried out The responsibility for providing

United Leeds Hospitals
MAURICE ELLIS

SIR,—As a casualty officer seeing many cases of injury I was interested in Dr Scott's letter

It is our experience here that a large number of patients who attend are able to tell us that they have been treated elsewhere for injuries and have been given injections, but they have no idea what they were given or why, and in many cases they are extremely vague about the time of the injury

It has been our custom for some time past to issue all patients in need of toxoid with a record card, on which is entered the amount of the toxoid given, the date on which it was given, and a reminder date for the reinforcing dose This card, which is of pocket size, is given to the patient with instructions that it should always be carried with him and produced whenever he has to be given any injection The amount of clerical work in filling in these cards has been found to be negligible

The card, which is obtainable from Messrs Burroughs Wellcome, contains space for the recording of any type of protective inoculation, with a small space for the blood-group In our experience the patients are pleased to receive these cards and do appreciate that it is in their interests that they carry them with them, and we have no difficulty in getting them to report on the appropriate date for their booster doses of toxoid

YOUNG GIRL, OLD GIRL?

SIR,—In a review in your issue of May 17 you speak of a young girl of nineteen, making use of what is now accepted terminology According to this system of classification, a girl is unequivocally juvenile, but a young girl is someone considerably older who might almost be described as a young woman, were that permissible It seems, however, that agreement is still lacking on the gradations that may correctly be used to bridge the gap between this phase and that later period when the young girl has finally acquired the status of an old girl

F CAMPBELL ROSE

ORAL TREATMENT OF PERNICIOUS ANÆMIA

SIR,—We are grateful for the comments on our article on pernicious anæmia by Dr Latner (May 17, p 1077), who has worked for so long in this field with such distinction. We feel, however, that to criticise the dose given in the first week and yet ignore the lengthy maintenance period on low dosage is somewhat eccentric We were quite aware that daily oral doses of 100 µg of vitamin B_{12}, no matter in what form it was given, would produce a response of some kind We were less interested in this initial response than in ascertaining whether the vitamin-B_{12}-peptide could maintain patients in full health over long periods on small doses We believe that the literature is already overcrowded with reports of short-term responses to various preparations and we had no desire to confuse the picture still further

Although it is true that responses can be obtained with 5 µg of vitamin B_{12}, the massive doses of “ intrinsic factor ” required to facilitate its absorption (one thousand to two hundred thousand times the amount of vitamin) indicate that such preparations are not really very effective on a weight basis We have not attempted, as yet, to determine the minimal effective daily dose of our preparation in terms of vitamin B_{12}, but no matter what this is finally discovered to be, as it is complexed with less than seven times its weight of peptide, it remains quite easily the most effective preparation for the oral therapy of pernicious anæmia yet described

Lastly we do not deny that there is some factor within the normal stomach which brings about the relevant proteolysis—indeed, that is precisely what we have already said in our article That, however, is totally different from believing in the existence of the “ intrinsic factor ”, as currently understood, which is supposed to combine with pure vitamin B_{12} to facilitate its absorption

J G HEATHCOTE
F S MOONEY

“ THESE DYING DISEASES ”

SIR,—Dr Vickers states in his letter of April 19 that “ cases of non-specific urethritis are now the major problem, and these are in need of general medical investigation and care ” If the V D service is disbanded, as he suggests, who will diagnose these cases from gonorrhœa and study the relation of promiscuous exposure to certain cases of urethritis? Who will investigate the various types of non-specific urethritis and study the relationship of urethritis and prostatic infection to rheumatoid arthritis and other rheumatic conditions I believe that the great majority of physicians, surgeons, and general practitioners are glad of the specialised help that venereologists can give in trying to solve these problems

In many of the large cities gonorrhœa itself is a major problem and the ultimate success of modern methods of treatment is by no means assured Contact tracing and follow-up of defaulters, therefore, remain essential to control the disease, and this would become impossible if the cases were scattered among practitioners

The V D departments have an important part to play in investigation of doubtful blood reactions in pregnancy In the genuine cases of syphilis, treatment and follow-up of mother and baby can best be done through an organised V D service The immigration from countries with a high rate of syphilitic infection makes this a formidable task in some areas

If, as Dr Vickers states, the majority of cases of late syphilis are treated by the physician specialising in the organ mainly affected, and not by a venereologist, then the incidence of late syphilis in this country must indeed be high and cause for grave national concern

One important problem is not dealt with either in Mr King's original article (March 29) or in subsequent letters This is the small-town clinic where in many instances the number of patients attending does not justify the expenditure on staff, buildings, and equipment Many of the patients in these areas travel to the nearest large centre where there is less chance of casual recognition There is no easy solution to this problem, and I think each individual clinic needs careful consideration to decide whether (*a*) better facilities would improve the attendance or (*b*) the clinic should close

The General Hospital,
Birmingham
G H KNIGHT

SIR,—The letter by Dr Willcox (May 24) about the increasing incidence of gonorrhœa in spite of antibiotic treatment recalls a conversation which I had with Sir Alexander Fleming a few weeks before his death

He told me that he thought the antibiotic era, especially in relation to venereal infections, would be over in about five years I replied that although he was more able to judge than anyone else, surely he underrated the value of penicillin

The alarming statistics of the increase of these "dying diseases" suggest that Fleming's statement was justified

London, W 1 T Anwyl-Davies

A LOW-RESISTANCE RESPIRATORY VALVE

Sir,—We are grateful to Dr Cunningham (April 5) for pointing out that our brief report (Feb 22) on a low-resistance valve gives the false impression that the valve of Bannister and Cormack is not of similar low resistance This was not intended Of the many valves examined, a few were included in our report, and two only were discussed—the valve of McKerrow and Otis, which has a large deadspace, and that of Bannister and Cormack The latter has hinged valve flaps operated by gravity, and although we regret that we have not had one of their valves to test, it seems unlikely that it could operate effectively during tests of maximum breathing capacity where respiratory rate may exceed 200 per minute

Pneumoconiosis Research Laboratory,
Braamfontein, Johannesburg S Zwi

CHANGES IN THE LIVER IN GLOMERULONEPHRITIS WITH ŒDEMA

Sir,—There is no doubt that the combination of renal and hepatic disease is not a coincidence, since both organs have excretory functions and may be damaged by the same toxic and infective agents, as in yellow fever and Weil's disease Practically all the studies published deal with the effect of liver disease on the kidneys

Boyd[1] could find no changes in liver-function tests in cases of nephritis We studied 51 patients with œdema—caused by acute glomerulonephritis in 13, subacute nephritis in 9, subchronic nephritis in 23, cardiac failure in 3, and malnutrition in 3 They were investigated by means of several liver-function tests, and repeated liver biopsies stained and examined for structure, protein, glycogen, and fat content

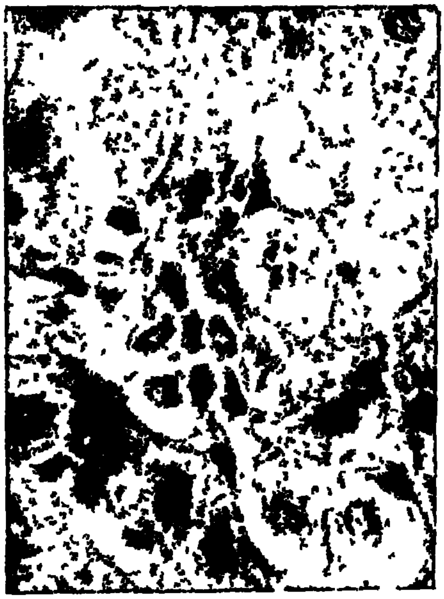

Fig 1—In the centre is a minute focus made of one or two disintegrating liver cells infiltrated by neutrophils (×450)

To summarise the results in the 45 cases of nephritis

1 *Clinical*—The liver was found to be progressively enlarging in proportion to the duration of the œdema in 40% of the cases of glomerulonephritis

2 *Liver-function Tests*—The galactose-tolerance test was disturbed in 62% and the galactose index in 80% of the glomerulonephritis cases Bromsulphalein retention was increased in 33% and thymol turbidity was increased in 25% Both the icterus index and Van den Bergh test were normal, while the alkaline-phosphatase figures were in the high normal range

3 *Liver Biopsy*—Examination of many serial sections revealed the presence of foci of disintegrated liver cells, varying in size from

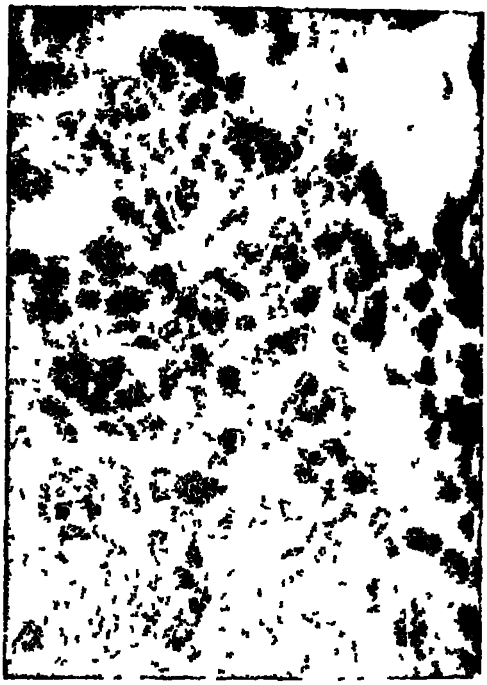

Fig 2—The middle half shows a massive focus, made of several disintegrating liver cells infiltrated by neutrophils and lymphocytes (×450)

small foci (fig 1), made up of one or two liver cells in early cases, to massive necrosis (fig 2) of one or two columns of liver cells in œdema of longer standing These foci were early infiltrated with neutrophils, then lymphocytes, and (in the massive necrosis cases) later fibroblasts and regenerating liver cells around them (fig 3) according to the duration of the œdema, the small foci healed completely The patchy appearance of the liver cells (cuboidal cells alternating with clear globular vaculated cells) denoting possible phases of functional activities, could be confirmed in the specimens studied

The factor responsible for these changes in the liver may be metabolic, the result of disturbed renal function, it may be related to the hypoalbuminæmia or vascular capillaries, or to bacterial emboli not dealt with by the liver because of loss of complement in the urinary protein, or it may be allergic, in view of the response of œdema in some cases to antihistaminic drugs[2] and the fall in the histamine-binding power of the blood in the cases studied

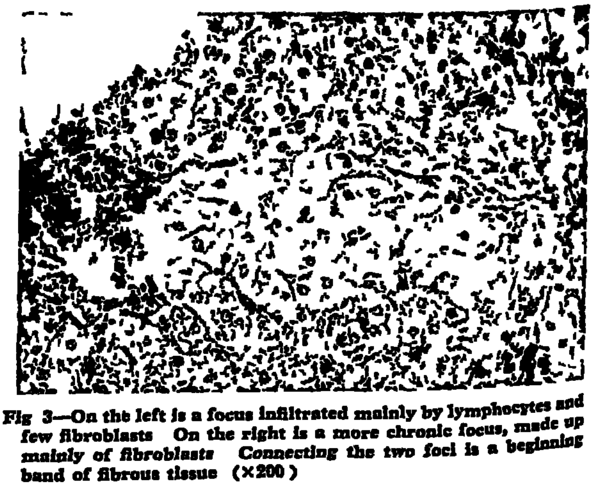

Fig 3—On the left is a focus infiltrated mainly by lymphocytes and few fibroblasts On the right is a more chronic focus, made up mainly of fibroblasts Connecting the two foci is a beginning band of fibrous tissue (×200)

VISITING MENTAL HOSPITALS

SIR,—Mr Woodley's letter in your issue of May 17 highlights the human problem of the long-stay often unvisited patient in our mental hospitals

Fortunately the picture he paints is no longer typical of mental hospitals in England and Wales, where most medical superintendents of mental hospitals welcome and encourage friendly visitors

A summary of replies to a recent questionnaire sent to medical superintendents of mental and mental deficiency hospitals in England and Wales by the National Association of Mental Health shows that visiting of friendless patients by members of voluntary organisations takes place in a majority of hospitals Leagues of Hospital Friends, the W V S, Rotary Clubs, and many women's organisations, such as Women's Institutes and Townswomen's Guilds, do most valuable service in this field

Several medical superintendents have indicated that further help would be welcomed, and this Association would be happy to make available details of any known needs to any responsible inquirers who would like to give help

The National Association
for Mental Health, London, W 1 D MCCLELLAN
Public Information Organiser

SIR,—I felt I must comment on Mr Woodley's letter

At Severalls Hospital we have many such patients whose relatives have ceased to visit for various reasons These patients look forward to visits from members of Women's Institutes, Inner Wheel, &c, who also send letters and gifts to the people they adopt and in suitable cases take them for outings

We are constantly encouraging the lay people to take an interest in our patients, and I am sure other mental hospitals do likewise

Severalls Hospital,
Colchester, Essex R E CLARKE

AN ALL-IN FAMILY SERVICE

SIR,—In your comments on our new pamphlet, *Families with Problems* (May 17, p 1080), there is an admirable summary of our proposals for a family welfare service You suggest that such a service would not necessarily reduce the number of "callers on the family's doorstep" because the social worker concerned with any family would still be expected to call on specialised help No social worker however can deal with all the medical, psychological, educational, and administrative problems that bedevil some families and he must needs be able to call on, for example, a doctor, a headmaster, a youth employment officer, or the National Assistance Board, for advice and help There is no reason at all why such help should result in more callers

You are evidently concerned lest our proposals would require new legislation You point to the work done by the social workers who have lately been given special responsibility for problem families under certain local authorities The appointment of such workers is a welcome attempt to reduce the duplication and waste of the present multiplicity of social services, but although they do a remarkable job of rehabilitation with many problem families, this is hardly "preventive work" We are naturally pleased at any move which begins to focus attention on "families" rather than on "problems", but we believe that preventive work is only possible when *all* families have access to help with their family problems in their early stages, either by asking for it themselves or by being referred by other agencies who are realising more and more that such matters as overcrowding, truancy from school, cruelty to children, non-payment of rent, and so on contribute to, or are indicative of, family stress Such a service will certainly require new legislation, but social legislation must be expected to keep in step with the awareness of social needs The family is once again being recognised as a most important social unit Legislation for the family must surely not be delayed

COMPLICATIONS OF RISTOCETIN THERAPY

SIR,—The increasing problem of antibiotic-resistant organisms, discussed in your leading article of March 8, has stimulated the development of a variety of new antimicrobial agents Among the more promising of these has been ristocetin, a lyophilised preparation derived from the fermentation broth of *Nocardia luria*,[1] and marketed under the trade name of 'Spontin' Advantages ascribed to ristocetin have included striking bactericidal activity against gram-positive bacteria and mycobacteria, the lack of development of resistant organisms, and the absence of cross-resistance with other antibiotics[2 3] Reported instances of toxicity have been few, and limited to neutropenia, leucopenia, and local phlebitis at the site of intravenous administration[3 4] Recent experience with ristocetin at Walter Reed Army Hospital has prompted this preliminary report

Results to date have confirmed the potent gram-positive bactericidal properties and the absence of resistant organisms, but they have emphasised the occurrence of toxic reactions especially when the dose of ristocetin was in excess of 50 mg per kg Eight of ten patients in this study developed hæmatological complications, including three cases of acute thrombocytopenia, as well as leucopenia and neutropenia Rash, hyperpyrexia, and local thrombophlebitis were also encountered

While contributing factors may have existed in certain patients, we feel that the complications were attributable to ristocetin Of considerable interest was the profound thrombocytopenia observed in two patients with acute renal insufficiency at a time when urine output was sharply curtailed In one of these the blood level of ristocetin *one week after discontinuing therapy* exceeded by threefold the customary therapeutic level In general, the complications seemed to be due to toxicity rather than individual idiosyncrasy, and they were reversible upon discontinuing therapy or reducing the dosage Subsequently, ristocetin has been used without adverse effects in a dose of 25 mg per kg in two cases

Preliminary experiments with rabbits have provided additional confirmation of the thrombocytopenic effect of ristocetin.[5] In addition, in-vitro studies now in progress have demonstrated a platelet-agglutinating factor,[5] which, together with the finding of a normal bone-marrow in two of the patients with severe thrombocytopenia, suggests a peripheral rather than central toxic action Much more investigation is needed, however, before conclusions can be drawn concerning the mechanism of production of these effects

Our findings reaffirm the clinical utility of ristocetin, especially in enterococcal and staphylococcal infections, but direct attention to potentially reversible hæmatological complications, including, for the first time, thrombocytopenia In the patients studied, toxicity seemed to be a function of dosage It is suggested that appropriate serial hæmatological studies be performed in all patients receiving this drug, and that extreme caution be observed in those with compromised renal function A more detailed report will follow elsewhere [6]

SPONTANEOUS RUPTURE OF THE ŒSOPHAGUS AND BRONCHIAL ASTHMA

SIR,—I was interested to read that Dr Raffle (May 3) had found no previous record of spontaneous rupture of the œsophagus in association with bronchial asthma, for this accident occurred in a patient here last year

An obese male, aged 62, was admitted with an acute exacerbation of his recurrent bronchitis, from which he had suffered for many years He was confused, cyanosed, dyspnœic, and wheezing Improvement followed treatment with antibiotics, intermittent oxygen, and aminophylline, but he remained confused Nineteen days after admission his condition suddenly worsened and he seemed to have had a pulmonary embolus He died within a few hours Postmortem examination revealed right ventricular hypertrophy, a purulent bronchitis, 14 oz of greenish mucoid fluid in the right pleural sac, 4 oz of bloodstained fluid in the left pleural sac There was a rupture of the stomach at the cardiac sphincter

The patient had not vomited before the rupture

I wish to thank Dr E Grahame Jones for permission to report this case

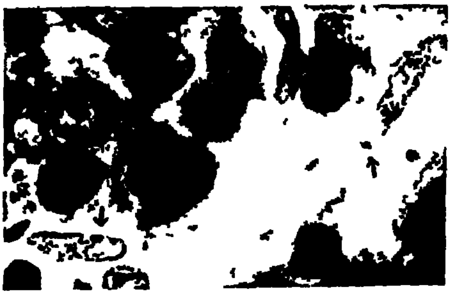
STAINS FOR SEX CHROMATIN

SIR,—According to Lindsay and Barr,[7] "the sex chromatin lacks well-developed argyrophilic properties" and "the accessory body is strongly argyrophilic and refractory to basic dyes, the reverse is true for the sex chromatin"

Forty-six years earlier Ramon y Cajal [8] wrote "Colloidal silver which always resists dyeing of the basophil substances and, strangely, of the nucleinic or chromatic framework of ordinary cells", and "colloidal silver never impregnates any material which is distinctly basophil, much less tissue treated with either neutral or slightly alkaline fixatives (for example, Nissl bodies, the reticulum of nuclein, &c)"



Sex chromatin two fibrocytes in a section of colourless nævus of breast from a woman aged 56 (stained with silver carbonate)

My personal experience is different, and I currently use silver methods in the routine dyeing of sex chromatin in very different kinds of healthy and pathological tissues It is easily done and when the impregnation with silver is good (a result not always obtained) the bright appearance of the cellular picture is entirely satisfactory, especially for photomicrography, because of the excellent contrasts obtained A good example is the accompanying photograph of a malignant tumour

My observations will be published more fully later

C BARRIO CUADRILLERO

A STRIPPER ASTRAY

SIR,—An adventure with a vein stripper may be of interest and a warning

In a very obese woman, a high resection and "flush tie" of the long saphenous vein at the saphenous opening was performed A *Myers*-type stripper was introduced in the long saphenous vein in front of the medial malleolus with the object of stripping out the vein It passed up very easily except for a slight check in the mid-calf A moment too late it was realised that the tip of the stripper had not appeared in the saphenous vein at the upper incision The stripper could be palpated in the femoral vein at the saphenous opening, the tip being higher up Gentle pulling failed to extract the stripper, the tip of which seemed to be caught or jammed above the inguinal ligament Pulling was tried with the leg in all possible positions, and the patient was tilted feet down to distend the veins, but still the stripper would not come

It seemed almost certain that the external iliac vein would be torn if the stripper was forcibly pulled Therefore an extraperitoneal exposure was made above the inguinal ligament The stripper was immediately found impacted in a small vein in the extraperitoneal fat $1^1/_4$ in above the inguinal ligament This vein appeared to be a small tributary of the external iliac vein The little vein was divided, and the tip of the stripper pushed through and cut off with wire cutters The stripper was then easily withdrawn and the ends of the vein tied The operation was completed by closing the incisions and the short saphenous vein was ligated behind the knee The patient recovered uneventfully, and there was no evidence of postoperative deep-vein thrombosis

The lesson to be learnt from this case is that the operator should always know exactly how far up the leg the tip of the stripper has travelled It is known that a stripper can enter the deep veins through one of the communicating veins, but I have never heard of any difficulty in pulling the stripper back again It must be very rare indeed for a stripper to enter the deep veins and then escape through a tributary, though the angle of junction just above the inguinal ligament might favour this Usually the stripper can be felt in its passage all the way up the long saphenous vein, and often, in thin people, it can be seen through the skin as well In obese people it can be very difficult to follow the course of the stripper, which could enter the deep veins without the operator's knowledge Perhaps the easiest way to be certain how far the stripper has travelled is to have another stripper of exactly the same length at hand so that the distance can be measured

The predicament described here occurred very easily and simply The consequences could have been serious if the stripper had been pulled too forcibly The importance of knowing the exact position of the tip of the stripper cannot be too strongly emphasised

RESIDENTIAL CHARGES ALLOWABLE AS INCOME-TAX EXPENSES

SIR,—I have recently been successful in a claim, to H.M. Inspector of Taxes, for residential charges to be allowed as expenses, and since I am sure this will apply to many others I feel it should be made known generally.

Where a married house-officer, senior house-officer, or registrar maintains accommodation for his wife, and holds a post which necessitates his being resident, a deduction, under paragraph 7, ninth schedule, Income Tax Act, 1952, will be allowed of the total additional expense for board and lodging which is incurred by him in the performance of his duties.

I hope others affected by this will find it helpful news.

Kent and Canterbury Hospital,

E. A. HARVEY-SMITH.

A SAFER WEEDKILLER

SIR,—Your columns have often carried justifiable warnings of the potential risks run by farmworkers and spraying operators in the use of the toxic herbicides dinitro-o-cresol (D.N.C.) and dinitro-butylphenol (dinoseb). D.N.C. has caused 8 of the 11 fatal cases of pesticide poisoning in Britain since 1946. Unfortunately, farmers cannot control all weeds in their cereal crops by using the non-hazardous "hormone" weedkillers such as 2,4-D and M.C.P.A. After a few seasons, "hormone-resistant" weeds accumulate, and a stronger weedkiller is needed. Although D.N.C. has been safely used to control hormone-resistant weeds for the past six years, neither this chemical nor farmworkers have changed their characteristics, and the potential risks remain. The pesticide industry has therefore continued to seek safer herbicides with broader spectra of use against weeds in corn, and several material improvements on 2,4-D and M.C.P.A. have become available in recent years.

The most recent development is trichlorobenzoic acid (T.B.A.), which, when added in quite small amounts to existing M.C.P.A. weedkillers, will kill or effectively control five increasingly common hormone-resistant weeds in corn—i.e., heriff (cleavers), mayweed, redshank, chickweed, and knotgrass. Hitherto many thousands of acres of corn have been treated with D.N.C. simply because these weeds were present and predominant.

The toxicity of T.B.A. has naturally been studied with much interest. It can exist in several isomeric forms of varying herbicidal activity. Their acute oral toxicity in laboratory animal species is low, LD_{50} values ranging from 300–1500 mg. per kg. depending on species, compared with 25–80 mg. per kg. for D.N.C. The most herbicidal isomers are among the least toxic to mammals. The oral LD_{50} of T.B.A. in the pheasant is about 1 g. per kg., and in the hen over 1.5 g. per kg. Percutaneous toxicity in the rat is extremely low, 1000 mg. per kg., applied for twenty hours under an impermeable covering, caused no toxic effects.

The cumulative toxicity of T.B.A. was tested by dietary feeding trials with rats lasting two months. Even 10 000 parts per million in the entire diet caused no mortality or obvious toxic effects, although there was histological evidence of cellular injury in liver and kidney. These effects were also present to some extent at 1000 p.p.m., but negligible at 100 p.p.m.

In all, fourteen isomers of di-, tri-, and tetra-chlorobenzoic acids have been examined, and all had low toxicity in mammals. Their presence as manufacturing impurities would therefore not decrease the safety of T.B.A. in agricultural use.

These isomers differ not only in their mammalian toxicity but also in their apparent mode of toxic action. Some of them caused an unusual "myotonic" effect even at non-lethal doses, the animals showing transient but severe muscular rigidity on handling. Other isomers failed to produce such myotonic effects, even at lethal doses. This type of myotonic response has already been described as one of the toxic effects of 2,4-D,[1] and is similar to that producible by veratrine alkaloids, 9-phenanthoate, and dihydronaphthacridine.[2] Details of the toxicological studies carried out on T.B.A. and its analogues will be published elsewhere.

Laboratory investigations are not always a reliable indication of risks in the field. Observations made during experimental trials in 1956–57, in which over 4000 acres were treated with various T.B.A. mixtures by farmers, spraying operators, and research-workers do, however, support the implication that T.B.A. is virtually non-hazardous in use. No reports were received or evidence brought forward of adverse effects among users, farmstock, bees, wildlife, game, or fish.

The problem of selective weedkilling in farm crops is still far from solved, despite the advances which are occurring. It will still be necessary to use the toxic dinitro-herbicides for weed control in some pea crops, or where cereals are undersown with clover. Nevertheless, it is just as pleasing to the pesticide industry as to the pharmaceutical industry when a new development, such as T.B.A., combines the virtues of effectiveness and every promise of safety in use.

E. F. EDSON.

DISPLAYING AXILLARY LYMPHATICS IN MASTECTOMY

SIR,—Many cases of lymphœdema of the arm following radical mastectomy and X-ray therapy are referred to me. I find these patients difficult to help and the operation I do gives only limited relief.

One feels that damage to the arm lymphatics during operation is the primary cause. Lymphœdema occurs more commonly in fat women than in thin, so greater care should be taken in the fat than in the thin in the extent of the axillary dissection. I will not go into the relative merits of radical mastectomy as opposed to local mastectomy in the cure of breast carcinoma, but to me the development of lymphœdema is a contra-indication to the bigger operation.

Obviously to avoid damage to arm lymphatics and at the same time to remove the breast lymphatics from the axilla, a method of showing these different lymphatics in the axilla is of great value, and this can easily be done by injecting 2.5 ml. of 11% patent blue into the subcutaneous tissue of the arm. Alternatively, a similar injection into the breast by the nipples will show the breast lymphatics. These injections give a most dramatic visualisation of lymphatics, and I would urge any surgeon who is doing a mastectomy to inject 2.5 ml. of patent blue into varied sites, some ten minutes before operating, injecting, in successive patients, into the subcutaneous tissue of the arm, intramuscularly into the arm, subcutaneously over the breast, intramammarily by the nipple, and between the growth and the axilla. Of these, the interesting one is the intramuscular injection of the arm which often shows no drainage via axillary lymphatics! I am in process of collecting data with a view to publication, unless I find that somebody has already done so. However, I would urge any practising surgeon to visualise for himself the lymphatics in the axilla, and he will note at once how many important arm lymphatics pass through the apparently useless axillary fat that lies above the vein. One warning—he should inform his anæsthetist because the patient goes a ghastly blue for several hours.

London, E.1.

CHARLES HEANLEY.

Parliament

Pollution of Rivers

The 1951 Act entrusts the defence of our rivers against pollution to the river boards, but it includes a proviso that for seven years the boards can only bring proceedings in respect to the discharge of trade effluents or of effluents from local authority's sewage works with the approval of the Minister of Housing and Local Government. The Act also makes provision for the extension of this period by Order in Council, and on May 17 Mr J. R. Bevins, parliamentary secretary to the Ministry, asked for its extension for another three years. The temporary restriction of the boards' powers had been imposed, he reminded the House, because it was feared that without some control over prosecutions, we might have been forced into capital expenditure which the country could ill afford. In the event, however, the river boards had been confronted with technical obstacles which so far had prevented them from devising byelaws laying down permissible quantity and quality standards for effluents. Against this background the Minister had asked the Central Advisory Water Committee whether the seven-year period should be extended and they had recommended that it should be extended by a further three years.

Since the 1951 Act became law, Mr Bevins recalled, there had been 25 applications for the Minister's consent to prosecute. Consent had been given in 7 cases and fines had been imposed by the courts. In the remaining 18 cases, the applications for consent to prosecute were withdrawn while remedial measures were being taken, and 5 of those were still under consideration. In only 1 case was consent to prosecute refused by the Minister. If the seven-year period was allowed to expire it would then be open to anyone alleged by a river board to be causing pollution to plead in defence that it was not reasonably practicable to dispose of the effluent other than by discharging it into the stream, and secondly, that all reasonable and practical steps had been taken to make the effluent not poisonous or noxious. If the court accepted that plea, then the person alleged to be responsible would not be liable to any penalty. This broad provision in the 1951 Act has been in suspense during the last seven years and would remain in suspense if the period of control was prolonged. Thus though the termination of the period might make it easier for the river boards to put pressure on alleged offenders, they would find it more difficult in cases of prosecution to sustain their argument before the court. But Mr Bevins added that he would not disguise for a moment that the fundamental difficulty was money. So long as we had restrictions on capital expenditure which might prevent the extension of sewage treatment works we could not ignore the fears of those in industry lest they should be caught between the difficulties of capital restriction on the one hand and prosecution on the other. The Minister was not in any way complacent about this problem: where he could he was authorising capital expenditure for sewage treatment works and sewage disposal. Since the war, schemes costing more than £200 millions had been sanctioned and there had been a steady increase in the last few years.

Members were less happy than Mr Bevins about the proposed extension. Mr Anthony Greenwood, as a representative of one of the dirtiest rivers in the country, viewed it with a good deal of dismay and suspicion. He suggested that it would in fact defer for another three years the granting of adequate powers to the boards. Though so much money had been spent on sewage schemes, improvement had not been rapid because towns were taking more and more water out of rivers above the town and putting back water into the river in the form of inadequately treated sewage below the town. The flow of many of our rivers had been seriously reduced. Until we had a national water plan this situation would continue. The Ministry which was responsible for curbing development of sewerage schemes was at the same time allowing water authorities to deplete our streams. During the three extra years now asked for our streams would continue to be polluted and there could be serious possibility of a grave epidemic. He reluctantly assented to the proposal, but thought that there should be no further extension and that the Ministry should really get down to the job of seeing that the river boards could discharge the task which had been entrusted to them.

Mr Edward Short said that the River Tyne had been described as an open sewer. Surely it could not be healthy to have this great sewer running through the middle of a densely populated industrial area. As he understood it, the local authorities were under no obligation, so long as the immunity existed, to find alternative methods of disposal, and they were under no obligation to render the effluent innocuous. Yet no part of the country was far from the sea. It was simply a question of money to take the industrial waste or sewage to the sea. Every year great new housing estates arose, and every year new industries developed with new and more deadly kinds of waste. In the future we might have nuclear waste discharged into our rivers.

Mr Bevins agreed that in certain areas there had been some deterioration in the state of our rivers. But the question was whether the removal of Ministerial consent would help to lessen pollution, and whether this would be the right time to remove that consent. He submitted that it would be unreasonable, at this stage, to expose people to the risk of prosecution when control over capital investment might be holding back the construction of modern sewage works through which most industrial effluents should pass. The figures for capital investment in sewerage works since the war did not support the view that the Government had been neglecting their duty. There was no evidence of a single scheme put up by a local authority which had been turned down, if it was essential in the interests of health.

The House agreed to ask for an extension.

QUESTION TIME

Suicide and the Law

Mr Kenneth Robinson asked the Home Secretary what further consideration he had given to the legal aspect of suicide and attempted suicide, and if he was aware that the law of England and Wales stands almost alone in regarding such acts as criminal.—Mr R. A. Butler replied: I am pursuing my study of this problem, which has practical aspects of no less importance than its legal aspects. I am not yet ready to reach a conclusion upon it. Mr Robinson: Is the Minister aware that a joint committee, set up by the *British Medical Association* and the Magistrates' Association, has reported in favour of a change in the law? In view of this weighty opinion, will not the Home Secretary make an early decision in this matter?—Mr Butler: I am aware of the report. I am also aware of various other considerations. I think this is a very difficult subject, but I will undertake to consider what the hon. gentleman has said.

Mr Gordon Walker: Would not the Minister agree that this is a matter which needs as early consideration and decision as possible? Would not he also agree that there are no real religious grounds for our law as to attempted suicide, and that this was due to a judicial decision about a hundred years ago? Is there not a great deal to be said for bringing our law into line with that of other countries?—Mr Butler: I have carefully studied the position in other countries and also the statistics of the convictions. For example, in 1956, proceedings were brought in 613 cases out of 5000 or more, and over 90% of these charges resulted in probation for the person concerned, and very few in sentences of imprisonment. I have also considered that in a minority of cases, without the power we have now, we might not be able to achieve the desired results, so that, on the facts, it is a very difficult question to decide.

Mr Robinson: Does not the Minister agree that other provisions of the law in regard to breach of the peace and mental health are quite sufficient to deal with the cases he has in mind?—Mr Butler: The Government's approach to mental health is at present actual, and does bring all this subject to the fore. It is against that background that I am examining it.

Wolfenden Report

Mr D L **Donnelly** asked the Home Secretary whether he was yet in a position to make a further statement regarding the Government's policy towards the Wolfenden report on homosexuality and prostitution —Mr **Butler** replied Many representations have been made since the report was published Some of them are in support of the committee's recommendations, but others are strongly critical This applies both to the main recommendations on homosexual offences and to those on prostitution It is clear that the committee's recommendations have stirred public opinion widely and deeply, and I would not propose to decide on a future course of action until that opinion has had the fullest opportunity of expressing itself

Composition of Milk Committee

The Minister of Agriculture, Fisheries, and Food has set up a committee

> To consider the composition of milk sold off farms in the United Kingdom from the standpoint both of human nutrition and of animal husbandry and to recommend any legislative or other changes that may be desirable

The chairman will be Dr J W Cook, vice-chancellor of Exeter University, and the 14 other members include Dr D P Cuthbertson, Dr Philip Evans, Dr H E Magee, and Prof B S Platt

Scientific Research

The Lord President of the Council has set up a committee, under the chairmanship of Sir Claude Gibb, with the following terms of reference

> "To inquire into the techniques employed by Government Departments, and other bodies wholly financed by the Exchequer, for the management and control of research and development carried out by them or on their behalf and to make recommendations "

The five other members include Sir Solly Zuckerman, professor of anatomy in the University of Birmingham

Obituary

Prof GEOFFREY RAKE

S C L writes

Surely a measure of the impact of a personality is the vividness of a memory recalled from afar I was a "clinical" with Geoffrey Rake in our first post-qualification appointment, and although I did not know him well then or at any time, he still looms out in strong silhouette against the misty background of his colleagues—and, for that matter, of most of his mentors

It was as a student that he did his meticulous work on achalasia of the cardia—a fragment of research that would have done credit to an experienced postgraduate He was serious, shy, meticulous, and obsessional, with bursts of gaiety I remember him best for one incident. After a bedside dissertation by a senior physician on the colour of the conjunctivum as an assessment of the hæmoglobin value, we were all made to examine a patient, and we guessed wildly in turn But Geoffrey Rake peered down for what seemed an interminable time into the eye of the patient, stood up, said "Eighty-five per cent," then reflected and said, "No, eighty-three per cent" Much as I would like to report that his considered opinion was correct, I cannot, for there my memory returns to the mists

Births, Marriages, and Deaths

DEATHS

Coates—On May 24 at Bridgwater Hospital, Somerset. John Francis Coates, M D M R.C.P, aged 50, husband of Eve, only son of Dr Richard Coates of Burnham, Somerset.

Notes and News

EDUCATION IN HEALTH AND NUTRITION

In many underdeveloped countries much of the new medical science cannot benefit the people until they have learnt something of the general principles that cause diseases to spread How such knowledge is best given was discussed at a seminar[1] in Baguio, in the Philippines, organised by the Food and Agriculture Organisation and the World Health Organisation, in October, 1955 It was attended by over 70 people, doctors, educationists, home economists, social workers, and others from many countries in Asia and it was directed by an international staff

The report is written by one of the delegates A single authorship allows a more lively style and outspokenness than is possible when, as in so many international reports, many authors are jointly responsible There is, for instance, a detailed criticism of the organisation and planning of the seminar This is useful, for the seminar itself was a major new venture in education, and future international seminars can profit from the experience gained Although, with a large subject, the discussions were necessarily diffuse, a few general principles emerged

1 No educational programme can be effective unless it is based on a knowledge of the way of life of the people and their own desires and ambitions Their beliefs, behaviour, attitudes towards health and disease and towards food must first be studied This can only be done by living amongst the people in their village

2 Education must have well-defined goals and objectives These must be expressed specifically for the areas in which it is hoped to bring about a change and must be stated in terms suitable for operations in small villages Full consideration must be given to the wishes of the community and the programme must be designed to fulfil needs felt by the people themselves In drawing up plans it is necessary to consult doctors and other health workers, educationists, economists, and agriculturists and, most important of all, local community leaders The recognition of such leaders and the enlistment of their cooperation is an essential preliminary

3 The techniques of education applicable for children in schools may be useless for adults In particular didactic teaching is of limited value Demonstrations are to be preferred and every effort made to involve as many members of the village as possible in the demonstrations Adult teaching is best based on groups with a common interest, which already exists in a community

Much health education in the past has been unprofitable owing to the use of techniques unsuited to the local community If waste of effort and money is to be avoided, a careful attempt at evaluation of the results of an educational programme must be made Such evaluation should not be left till the end, but should be made periodically to find out whether the programme is developing as planned

There is much valuable detail in this report, and all concerned with promoting the health and welfare of village life in the tropics will be able to learn something of value from it

INITIAL SALARIES OF CONSULTANTS AND S H M.O s

The Minister of Health (H M [58] 38) has asked hospital boards to take account of a submission by Committee B of the Medical Whitley Council The committee points out that, under the Terms and Conditions of Service of Hospital Medical Staff, consultants and senior hospital medical officers appointed at age 32 or over are to be paid under incremental scales, subject to the discretion given to boards to fix the starting salary up to four incremental points above the minimum (1) by reason of age, special experience, and qualifications, or (2) by reason of age alone, where seniority has been lost because of service with the Forces Committee B reports that a higher proportion than might have been expected have on appointment been placed at the minimum point on the scale The committee says that boards should consider exercising their discretion in each case on merit, and it suggests that boards might look for advice to the Advisory Appointments Committee

Lord Cohen of Birkenhead has been elected president of the society

Cleaner Rivers

Addressing the River Boards' Association on May 16, Mr Henry Brooke, Minister of Housing and Local Government, said that " within the not too distant future we are going to see a quite outstanding improvement in our rivers, and my aim is to make their amenity value and their recreation value match their utility value" Though the River Boards Act of 1948 and the Rivers (Prevention and Pollution) Act, 1951, give effective powers for dealing with river pollution, it had not yet been possible to find more than a part of the huge amount of money needed to overcome the neglect of over a century Nevertheless, since the war, local authorities had spent more than £205 million on sewerage and sewage disposal, the greater part on disposal works bound to benefit the rivers into which effluents were being put In 1957—a difficult year—£28 million of works had been authorised by the Ministry, against £15 million in the preceding year and a pre-war average of £$5^1/_4$ million On top of this were the very large sums spent by industry on pre-treatment of trade effluents " Improvement and restoration must be a gradual process The task we have to tackle jointly is to determine, from time to time and from place to place, what limits of pollution are to be tolerated, and then to endeavour over the years to reduce those limits " Members of the Government had to find a balance between the many demands on the country's capital resources, and a balance too between the interests of urban and industrial development (which necessitated effluent disposal and sometimes water abstraction) and of those who enjoy the countryside and the fishing, who rightly and forcefully criticised and opposed them

THE PLACE OF HUMAN BIOLOGY IN MEDICAL EDUCATION

SUGGESTIONS FOR A REVISED PRECLINICAL COURSE IN THE LIGHT OF THE GENERAL MEDICAL COUNCIL 1957 RECOMMENDATIONS *

J M Tanner
M B, Ph D, D Sc Lond, M D Pa, D P M
SENIOR LECTURER IN GROWTH AND DEVELOPMENT, INSTITUTE OF CHILD HEALTH, UNIVERSITY OF LONDON †

How one trains medical students depends on what view one takes of medical practice Furthermore, as every teacher of the so-called basic medical sciences experienced in spreading pearls before the jaundiced eyes of students hell-bent on doctoring will agree, how the medical student trains himself depends on what view *he* takes of medical practice

If teacher and student think of practice primarily as the mending of broken bones, then they will think of training primarily as anatomy plus surgical technique, with a little pathological physiology and a little bacteriology thrown in If they think of practice primarily as treating patients with heart-disease, they will think of training as physiology plus pharmacology, one hopes with a little patience thrown in If they think of practice as condemning slums, purifying water, and destroying mosquitoes, they will think of training as bacteriology and parasitology with a little engineering thrown in

But if they think of medical practice as an endeavour to understand individual people in relation to their hereditary endowment, their upbringing, their family, their social position, and their whole culture, and as an endeavour to guide them, so far as may be, from childhood to old age through the squalls and doldrums so that they slip as seldom as possible over that invisible equator which divides health and disease, whether of mind or body, if they think of medicine as such an attempt, such an activity, how *then* do they think of training? Certainly *not* as a series of scarcely connected courses in physics, chemistry, anatomy, and physiology culminating in instruction by a multitude of specialists each on how to be an elementary specialist in his own particular field—though this, with little amelioration, is our almost universally practised system Fundamentally, of course, their thinking depends on what view teacher and student take of the nature of man, and of man's place in Nature I need scarcely remind you—but I am certain we must continually remind many others—that this year is the Darwin centenary

It is my thesis here that the practice of medicine as it is developing in European and American cultures, and perhaps throughout most of the world, is most usefully thought of as *applied human biology* Taking a strictly naturalistic and post-Darwinian view of man, doctors should be thought of as applied human biologists, and this in exactly the same sense in which we currently use the words "applied biologist" when discussing the role in society of the pest-control officer By this I do not wish to imply a one-sided belief in negative eugenics coupled with a despairing cynicism for our species! Nor do I mean in any way to overlook or displace from priority the duty of the doctor to cure, when sick, the individual patient I mean quite simply that the applied biologist, from pest-control officer to game-warden, is a recognised figure who helps us understand and control the numbers, ecology, behaviour, disease, and individual welfare of various species from bedroom pests to big game

That the applied human biologist should do likewise is, I am aware, a great claim It is not quite so great a claim as may appear at first sight, the *policy* of the applied biologist—whether we want more or less big game and so forth—is determined, at least in theory, by Governments and not by the biologist His role is that of adviser and implementer Similarly with the doctor as I see him, only here the superior authority is the culture itself, or its arbiters—Government, the Law, religion, and the organs of public opinion I am thus not claiming for him the role of ruler (though Heaven knows we might do worse than stake such a claim in our present confusion), but I am claiming a very wide field of operation as adviser and implementer

To tell the truth the doctor is already in one guise or another occupying most of the field The general physician is taking over increasingly the advisory (as distinct from absolutional) role of the priest, the psychiatrist is continually battering at the ramparts of the Law Abnormal behaviour is now as much their province as abnormal physiology Thus there is nothing in the slightest revolutionary or even new in what I am saying I only wish to make the point that we have not yet fully recognised the situation, or at any rate have not recognised it sufficiently to reflect it in our medical curriculum

If doctors are applied human biologists, then their basic training, before the clinical application, should be in human biology The orientation of their course should be analogous to the orientation developed for the animal biologist by J Z Young in his magnificent new textbooks *Life of Vertebrates* and *Life of Mammals* What we need is a *Life of Man*

The Place of Studies of Growth and Constitution in the Curriculum

It is against this background that I see the place in the curriculum of the studies of human growth and human constitutional variation Both are basic ingredients of a curriculum on the lines I envisage, and both should be taught early and to all medical students, and not late and to a few specialists, as is almost universally the case now The biological facts of human growth (and, of course, decay) provide the best possible background for the study of the family, the social group, and the variety of subcultures which the student should certainly engage in The life-cycle orientation, the study of growth and senescence, would also, I believe, be the answer to all modern educators' prayers—how to fuse the separate disciplines of anatomy, physiology, pathology, &c, without introducing a philosophical artificiality which carries the elements of its own disruption It is perfectly clear to everybody, though intensely disliked by all (except students) that the details of all our present subjects must be omitted at the undergraduate non-specialist stage, I am *not* suggesting that they be replaced by the details of the growth process I am suggesting that the passage of time, the biological principle itself, be used as the binder of diverse approaches, techniques, and disciplines

---

* An address written for the Ciba Symposium on The Scope of Physical Anthropology and Human Population Biology and their place in Academic Studies (November, 1957) on the requested theme The Place of Studies of Human Growth and Constitution in Medical Education

† Working at the Child Study Centre of the Institutes of Education and Child Health

As for human constitution, I envisage it as the basic common building material out of which are fashioned the different cultures and subcultures erected by men in various times and places If we are to understand the variety of these cultures and subcultures, and if we are to envisage accurately the possibilities of cultures struggling for birth, then we must know, and must teach, all we can about the nature and variety of our basic material

Giacinto Viola, professor of medicine at Bologna, and perhaps the greatest constitutionalist of this century, defined his subject as " the science of individual variations and nothing else ", and constitution as " the total of all the morphological and functional characters by virtue of which an individual differs from other individuals " If we compare this statement with J B S Haldane's definition of genetics as " the branch of biology which is concerned with innate differences between similar organisms " we see that the only difference between the two statements lies in the word " innate " The majority of constitutionalists do not wish to be restricted absolutely to the study of innate differences, but this is very largely because in the human the contributions of heredity and environment are so difficult to disentangle

I need hardly remind you of the wide disparity between this view of the place of growth and constitution in the curriculum and its actual position, which is practically non-existent At present very few departments of anatomy teach anything worth while, or indeed anything at all, about human growth A small fraction of the life cycle may be touched upon in the embryology course, it is true, but if life begins at 40, or even at 40 weeks, then most anatomical departments still slumber secure in the womb of tradition

There are signs that quickening has occurred, however It is significant that in the newest British textbook of anatomy a chapter on growth appears for the first time Certainly it is by far the shortest and least detailed section of the book, and it is illogically placed at the back end, thus giving something of the impression of a movie run backwards to any occasional student who manages to get that far after his studies of adult detail, nevertheless, it is there

The teachers of undergraduate pædiatrics, with one or two significant exceptions, do little to amplify the student's basic knowledge of growth They serve a small and relatively newly arrived specialty and they have little teaching time even for their strictly medical problems Usually they content themselves with a lecture or two on behavioural development during the first few years of life At least two American textbooks of pædiatrics, however, have quite long and excellent chapters on growth and development, it is to these I have to refer my post-gradute students, who arrive for their specialist pædiatric training at the Institute of Child Health for the most part, knowing, I am sorry to say, virtually nothing at all about how children grow

The teaching of human constitutional variation—morphological, physiological, and behavioural—is equally, but more understandably, neglected Studies of constitution at the undergraduate level must naturally be bound up with human genetics, and this is a subject that has made as yet little headway in most medical schools Though a considerable number of anatomists have genetical leanings, the great majority of professional physiologists are quite uninterested in and uninformed about the subject, perhaps the physiological aspects of constitutional differences have more hope of entering the curriculum through the agency of the chemical pathologist As it is, only when they reach their course in psychiatry do students meet constitutional conceptions, the tradition of Kretschmer, and the relative clarity of the relations between physique and mental disorder in a field where objective relations are so few, still sees to that

A New Preclinical Curriculum

With some temerity but very sincerely, I suggest that the preclinical medical course ought to be remodelled and unified into a course on the *Life of Man* Coming down to brass tacks, just *how* could the early part of the curriculum be remodelled ? Just how could the idea of the maturing process, the passage of time and the acquisition of experience in the life of the organism, be used to cement together our presently scattered bricks ?

The First Part

The first part of the course may be called *Cellular Biology* It would last certainly three whole terms, possibly four or even five We assume a universal background of elementary (i e , General Certificate of Education) English, mathematics, physics, chemistry, and biology We assume also for some students advanced G C E level in three subjects, which personally I believe should be English and mathematics compulsorily, together with one other, preferably chemistry, physics, or biology But most students would enter medical school at 17, not 18, since the entire course to qualification occupies six years

The lines of the cellular biology course are fairly obvious, bearing in mind that structure and function are to be strictly integrated (which is as easy at the cellular level as it is sometimes difficult at later stages in the course), and that biochemistry, genetics, and evolution are to be made similarly inseparable in the student's mind Pathology—i e , cellular pathology—is introduced right from the start every function can go wrong, and when we know the result of any particular going wrong in terms of cellular or medical disease, we describe it It is a very short step from the genetical biochemistry of *Neurospora* to the fundamental lesions of sickle-cell anæmia, alkaptonuria, and beriberi Behaviour also is introduced from the start, ethology will be our constant companion throughout the course until it leads without any break into human behaviour as developmental human psychology, sociology, and anthropology

Thus, for example, we begin by describing the appearance and histochemistry of relatively unspecialised mammalian cells, together with the biochemical energetics by which they maintain their structural integrity, and fulfil their particular function Alteration in function conditioned by genetic changes leads to a study of chromosomes, the mechanism of cell-division, and the principles of genetics Viruses and bacteria are introduced as examples of unicellular organisms and their ecology and place in evolution described The growth of cells in tissue culture is studied (practically also) and the factors controlling it The behavioural ideas of maturation versus learning are introduced in an elementary way even at this stage, and the behaviour of unicellular organisms and of cells such as leucocytes is shown, largely through cine films

DIURETIC ACTION OF CHLOROTHIAZIDE

N A MATHESON
M.B Aberd
LECTURER IN MATERIA MEDICA

T N MORGAN
M D Aberd, F R C.P
READER IN MATERIA MEDICA AND THERAPEUTICS

UNIVERSITY OF ABERDEEN

IT has been claimed that oral chlorothiazide (6-chloro-7-sulphamyl-1, 2, 4, benzothiadiazine-1, 1-dioxide), synthesised by Novello and Sprague (1957), is effective in the treatment of certain types of œdema Bayliss et al (1958) have used it successfully in congestive heart-failure and premenstrual œdema, Slater and Nabarro (1958) in œdema due to the nephrotic syndrome (3 cases) and œdema due to hepatic fibrosis with portal hypertension (1 case)

The chemical structure of chlorothiazide suggests that it acts by inhibiting carbonic anhydrase, and Beyer et al (1957) have shown that in vitro it is, in this respect, some thirty times more potent than acetazolamide ('Diamox') Slater and Nabarro (1958) have tried to assess the effect of chlorothiazide as a carbonic-anhydrase inhibitor in vivo by giving 3000 mg orally to a patient with rheumatic heart-disease and essential hypertension

Despite fairly extensive investigations on dogs (Beyer et al 1957, Ford et al 1957) and on patients with incipient heart-failure (Ford et al. 1957) there is no information about the effect of chlorothiazide on the urine and the excretion of electrolytes in healthy people The present investigation was an attempt to supply some of the essential basic information which cannot be deduced either from experiments on animals or from clinical trials Consequently we sought to determine the effect of chlorothiazide on the composition and flow of urine in healthy adult males, to assess its action in vivo as a carbonic-anhydrase inhibitor, and to compare its effect with that of acetazolamide

Methods

Investigations were made on 10 healthy males, aged 16–40, permitted normal activity and diet The intake of sodium and potassium was not accurately standardised, but on the days of experiment the intakes of food and fluid were qualitatively and quantitatively similar

Each man was studied during a control period of twenty-four hours His bladder was emptied at 9 A M, and his urine was collected under mineral oil in two-hour fractions for twelve hours The urine passed during the subsequent twelve to twenty-four hours by 5 men was collected with similar precautions and pooled The volume and pH of each sample were determined, and the urinary content of bicarbonate, chloride, phosphate, titratable acid, ammonia, sodium, and potassium during each period was measured

On a subsequent day at 9 A M each man received chlorothiazide 2000 mg by mouth, and the observations on the flow and composition of the urine were repeated The experiment was repeated on 3 men under similar conditions but with acetazolamide 500 mg instead of chlorothiazide When this was done, at least a week was allowed to elapse between the administration of the drugs to allow fluid and electrolyte balance to return to normal

The action of intravenous chlorothiazide 500 mg was also studied by collecting samples of blood before and at half-hour intervals for four hours after the administration of chlorothiazide. The hæmatocrit, plasma-carbon dioxide, plasma-chloride, serum-sodium, and serum-potassium were estimated in each sample Strict anaerobic precautions were observed in collecting the plasma for estimating carbon dioxide and chloride. Urine was collected and analysed, as in the previous experiment, before and each hour for four hours after the administration of chlorothiazide

Chemical Methods

Sodium and potassium were estimated by flame photometry, urinary chloride by modified Volhard-Harvey titration (Peters and Van Slyke 1932), plasma-chloride by the open Carius method as applied by Van Slyke, Sendroy, and Eisenman (Peters and Van Slyke 1932), carbon dioxide in plasma and urine by manometric methods, and urine bicarbonate from the ordinate of the carbonic acid-bicarbonate curve according to pH (Peters and Van Slyke 1932) Urine pH was estimated with the glass electrode, ammonia by

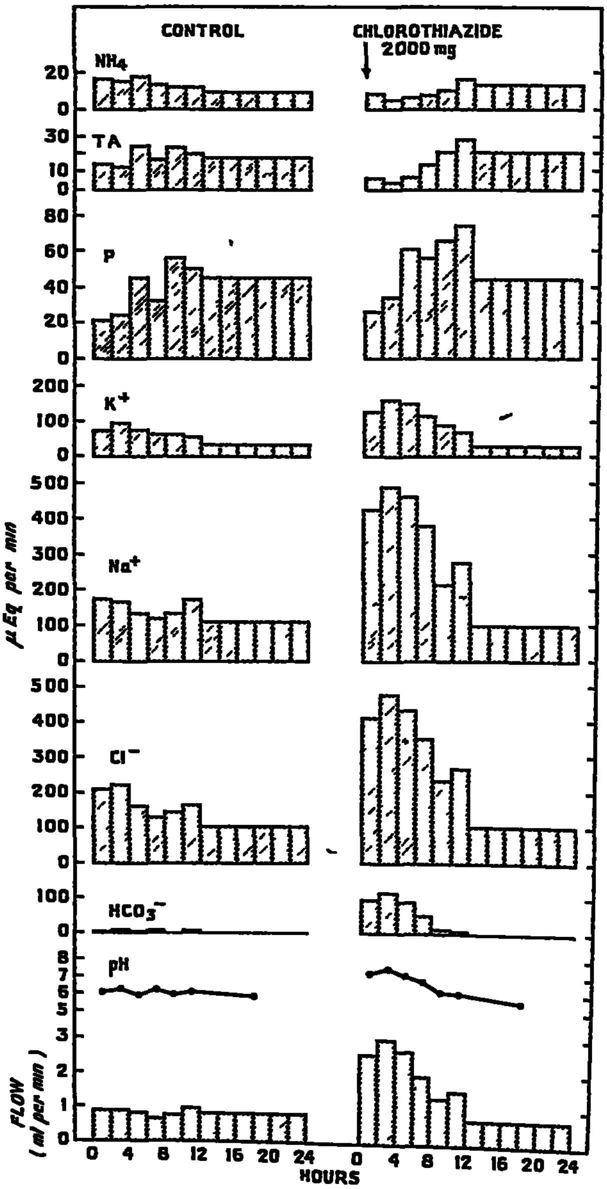

Fig 1—Average rates of excretion of water and electrolytes in 10 men after oral dose of chlorothiazide 2000 mg compared with rates of excretion during control period Note increase in excretion of sodium and chloride

Results

ORAL CHLOROTHIAZIDE

In the healthy men chlorothiazide 2000 mg had a pronounced diuretic effect associated with characteristic and constant changes in the excretion of electrolytes Fig 1 compares the average rates of excretion of urine and electrolytes for 10 men after the administration of chlorothiazide with those during the control day The changes in the rates of excretion of the various electrolytes after the administration of chlorothiazide are also compared with those during the control day Table I shows these results

TABLE II—AVERAGE EXCRETION OF URINE AND ELECTROLYTES OVER FIRST SIX HOURS

	K^+	82	146 8	+64 8	10 06

T A, titratable acid

Duration of Action

The diuretic effect appeared within two hours of oral administration, was well maintained over the first eight hours, and thereafter subsided but was not quite complete by twelve hours During the second twelve-hour period the excretion-rates returned to control values The form of the effect was the same for all measurements, rising to a maximum at about four hours (except for inorganic phosphate, whose maximum was reached somewhat later)

Table II shows the average increases over the first six hours after administration, the period of maximal action The standard errors of these figures are also given All changes of rates are considerable, even the smallest is such as to appear less than once in twenty times by chance if the chlorothiazide had had no effect

Formation of Urine

Over the first twelve hours the average output of urine was 2 6 times as great as during the control period, and almost a litre of excess urine was excreted in the twenty-four hours following the administration of chlorothiazide

Excretion of Sodium

The average excretion of sodium for twelve hours after the administration of chlorothiazide was 2 5 times that of the control and was increased 3 5 times during the maximal diuresis The average output of sodium over twenty-four hours after the administration of chlorothiazide was 342 mEq compared with 185 mEq during the control day

Excretion of Potassium

Chlorothiazide augmented the excretion of potassium to a lesser extent, the average loss over twelve hours being 1 6 times as great as the control The average output in twenty-four hours was 107 mEq after the administration of chlorothiazide compared with a control value of 75 mEq

Excretion of Hydrogen Ions and Bicarbonate

The rate of excretion of hydrogen ions, estimated from the titratable acidity and ammonium content of the urine, fell initially to about a third of the control rate (fig 1) Simultaneously the pH of the urine increased, and the excretion of bicarbonate increased to an average maximal rate which was 30 times the control rate These changes

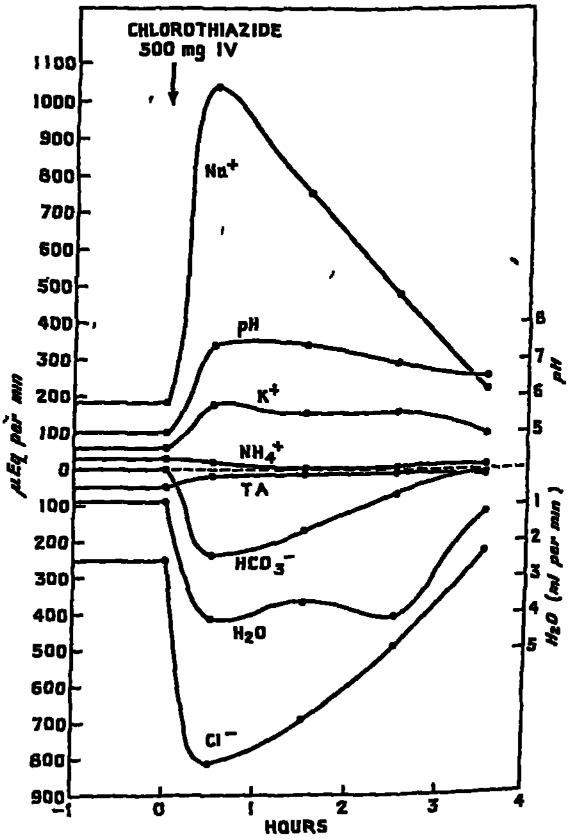

Fig 2—Pattern of excretion of electrolytes after intravenous dose of sodium chlorothiazide 500 mg

were maximal over the first six hours and complete by ten hours Thereafter the excretion-rate of hydrogen ions rose above the control rates as acid-base balance was restored

Excretion of Chloride

Chlorothiazide produced a striking increase in the excretion of chloride, approaching that of sodium Over twelve hours the rate of output was more than twice the control, and about 140 mEq was lost in twenty-four hours

Excretion of Inorganic Phosphate

The excretion of inorganic phosphate was also increased significantly throughout the period of diuresis The effect on the excretion-rate of this ion was not dramatic, and the maximal increase occurred later than in the case of other electrolytes

INTRAVENOUS CHLOROTHIAZIDE

The patterns of urinary excretion following the intravenous injection of 500 mg of the sodium salt of chlorothiazide are shown in fig 2 The changes were maximal within the first hour, and the effect lasted about four hours

The initial response was greater than that produced by oral chlorothiazide 2000 mg, but lasted a much shorter time, the loss of water, sodium, potassium, chloride, and bicarbonate being about two-thirds of the average loss following the oral administration of chlorothiazide

No change was found in hæmatocrit, plasma-carbon dioxide, plasma-chloride, serum-sodium, and serum-potassium levels during the four hours' observation

COMPARISON WITH ACETAZOLAMIDE

3 men whose response to chlorothiazide 2000 mg had been observed, were given oral acetazolamide 500 mg after an interval for recovery from the administration of the chlorothiazide The results are summarised in fig 3, where the average rates of excretion of urine and electrolytes after each drug are compared with the average rates during the control day

Chlorothiazide produced its maximal effect more rapidly than did acetazolamide, and its action lasted a shorter time In the second twelve-hour period following the administration of acetazolamide the flow and the pH of the urine and the excretion-rates of potassium, hydrogen ions, and bicarbonate had not returned to control values, whereas the action of chlorothiazide was almost complete by twelve hours

Over twenty-four hours acetazolamide produced a greater volume of urine, but more sodium was excreted after the administration of chlorothiazide The urinary excretion of potassium after the administration of acetazolamide exceeded the average control excretion by 70–80 mEq compared with 25–35 mEq after the administration of chlorothiazide Fig 3 brings out the important difference between the action of the two drugs on the urinary excretion of chloride, which was greatly increased during chlorothiazide diuresis but unaltered after the administration of acetazolamide, which caused a more striking and persistent increase in the pH of the urine and in the urinary excretion of bicarbonate and a greater decrease in the urinary excretion of hydrogen ions (fig 3)

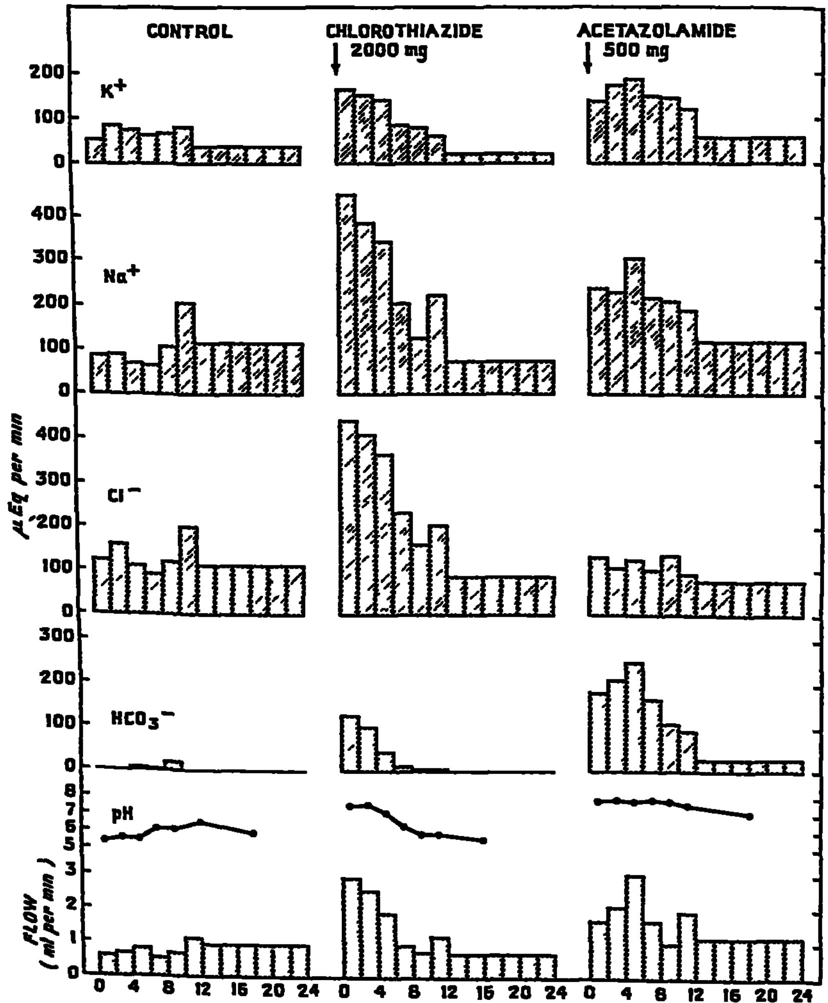

Fig 3—Average rates of excretion of water and electrolytes during control day, after oral dose of chlorothiazide 2000 mg., and after oral intravenous dose of acetazolamide 500 mg in same 3 men.

BASE ECONOMY

The difference between chlorothiazide and acetazolamide as regards the urinary excretion of hydrogen ions and bicarbonate is shown by the base economy after the administration of both drugs

The term "base economy" denotes the conservation of body base by the excretion of acid radicals, in excess of base, in the urine (Gamble et al 1923, Gamble 1949)

This is accomplished by the excretion of weakly acid components in urine, whose pH is so much lower than that of plasma that they can exist relatively base-free, and by the excretion of radicals of strong acids as ammonium salts The titration of urine to the pH of plasma gives an estimation of the free acid, and this together with the ammonium content is a measure of base

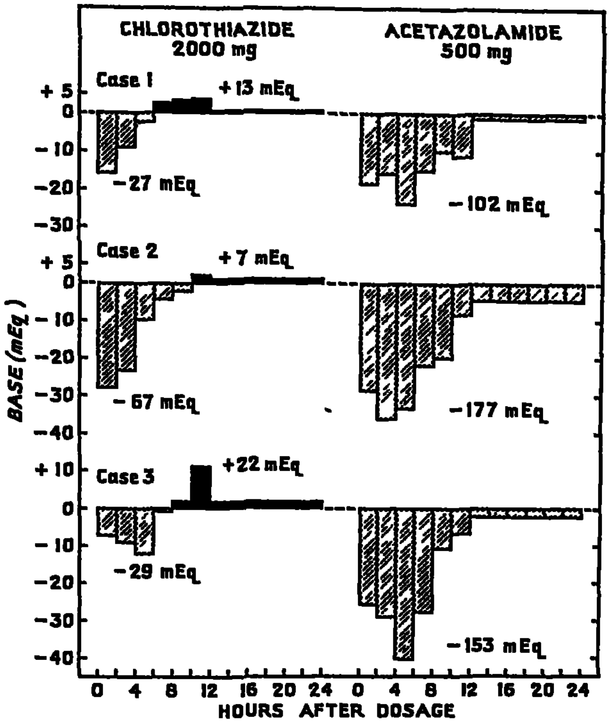

Fig 4—Comparison of depletion and recovery of base after single doses of chlorothiazide 2000 mg and acetazolamide 500 mg in 3 men Histograms below line represent loss of base, histograms above line indicate conservation of base and thus represent beginning of restoration of acid-base balance Note short-lived and relatively slight base deficit after dose of chlorothiazide

conserved Carbonic acid, normally excreted base-free by the lungs, may in certain circumstances pass into the urine as bicarbonate combined with fixed base and thus represent depletion of the alkali reserve Therefore, if urine bicarbonate is subtracted from the sum of titratable acid and ammonium content, the resulting figure, expressed in mEq , is a measure of base economy

The base economy following the administration of chlorothiazide may be calculated for any given period, if the value for the same period during the control day is subtracted from this figure, the result will represent loss or gain of base caused by the chlorothiazide (Maren et al 1954) Fig 4 compares the base deficit produced by chlorothiazide with that produed by acetazolamide Columns below the line represent loss of base, and columns above the line indicate conservation in excess of control values and thus the restoration of normal alkali reserve

This figure shows that chlorothiazide caused, in these 3 men, a total depletion of 27–67 mEq of base, and that recovery began in eight to ten hours or earlier Acetazolamide, on the other hand, produced a depletion of 102–177 mEq of base, and no recovery was evident within twenty-four hours

Discussion

In the renal tubule cells carbonic anhydrase catalyses the combination of carbon dioxide and water to form carbonic acid, which ionises to liberate hydrogen ions These ions pass into the tubular urine in exchange for sodium and combine with bicarbonate to facilitate its reabsorption as carbon dioxide and water The physiological function of the enzyme is thus the conservation of base by promoting reabsorption of sodium and bicarbonate, by increasing the excretion of hydrogen ions and by lowering the pH of the urine Further, it is believed that a competitive mechanism exists between potassium and hydrogen for tubular transport (Berliner et al 1950) Accordingly carbonic anhydrase must limit the tubular secretion of potassium A carbonic-anhydrase inhibitor, by preventing these processes, greatly increases the excretion of bicarbonate, moderately increases the excretion of water, sodium, and potassium, increases the pH of the urine, and decreases the excretion of hydrogen ions The action of acetazolamide in inhibiting the enzyme is well known (Friedberg et al 1952, Counihan et al 1954)

The observation that chlorothiazide inhibits carbonic anhydrase in vitro, together with the characteristic changes which it causes in the excretion of water, bicarbonate, sodium, and potassium, suggests that carbonic anhydrase inhibition plays a part in the action of chlorothiazide, but the pattern of excretion of electrolytes after the administration of chlorothiazide is sufficiently different from that seen after the administration of acetazolamide to make it certain that there is an additional action

The increase in excretion of sodium and chloride in about equimolar amounts is a characteristic feature of chlorothiazide diuresis It is likely that the therapeutic value of chlorothiazide will depend on this latter property

The urinary excretion of inorganic phosphate was increased after the administration of chlorothiazide This does not happen in osmotic diuresis (Havard and Reay 1926, Mudge et al 1949) Although increased excretion of phosphate is assocated with acidosis (Harrison and Harrison 1941, Pitts and Alexander 1944), it is unlikely that this will explain the increase after the administration of chlorothiazide, because acidosis must be minimal after a single dose of this drug

From comparison of the effects of chlorothiazide and acetazolamide on the urinary excretion of bicarbonate and hydrogen ions it seems reasonable to deduce that chlorothiazide is less potent than acetazolamide as a carbonic-anhydrase inhibitor in vivo Consequently the acid-base balance is rapidly restored after the administration of chlorothiazide (fig 4) Acetazolamide in repeated doses has a self-limiting effect because systemic acidosis and decreased glomerular filtration of bicarbonate result from its action (Nadell 1953, Counihan et al 1954, Hanley and Platts 1956), but chlorothiazide has a sustained effect (Ford et al 1957), and this difference is explained partly by the rapid restoration of the acid-base balance and partly by the action of chlorothiazide on the excretion of sodium and chloride, to which most of its diuretic effect is due

Chlorothiazide tends, especially during prolonged administration, to produce hypopotassæmia (Bayliss et al 1958, Slater and Nabarro 1958) In our experiments using single doses the excretion of water and potassium was greater with acetazolamide than with chlorothiazide, but, since the effect of chlorothiazide is unlikely to be interrupted by acidosis, repeated doses of it will lead to a greater loss of water and potassium

Summary

In healthy men oral chlorothiazide 2000 mg is an effective diuretic The action begins within two hours of administration and lasts for at least twelve hours

Chlorothiazide causes a pronounced increase in the urinary excretion of sodium, chloride, and water, an increase in that of bicarbonate, potassium, and phosphate, and a decrease in that of hydrogen ions

The action of chlorothiazide may be due in part to carbonic-anhydrase inhibition, but its striking effect on

the urinary excretion of chloride suggests that another mechanism is involved

Compared with acetazolamide 500 mg, chlorothiazide 2000 mg is a less potent carbonic-anhydrase inhibitor, hence recovery of base is more rapid

The action of chlorothiazide is likely to be maintained and, because of this, may induce hypopotassæmia

We wish to thank Dr D Finney and Mr R Cormack for statistical analysis and suggestions about the presentation of the tables, Dr J J E Merry, of Messrs Merck, Sharp and Dohme, Ltd, for a generous supply of chlorothiazide ('Saluric'), and the volunteers who took part in the experiment

CHLOROTHIAZIDE, a benzothiadiazine derivative, is a non-mercurial diuretic which has been reported to be effective and safe on oral administration (Bayliss et al 1958, Slater and Nabarro 1958, Ford et al 1958) Further investigation is necessary before its pharmacological action is fully understood, especially on its effect on the passage of electrolytes through the kidney

We have investigated the nature and degree of diuresis obtained with chlorothiazide in various clinical states associated with retention of fluid Twenty-six "acute" experiments were performed on 22 patients with the following clinical conditions

Congestive heart failure	9
Cor pulmonale with cardiac oedema	3
Pre-eclamptic toxæmia of pregnancy	3
Chronic azotæmic uræmia	1
Nephrosis	1
Hypertension	2
Hepatic cirrhosis with ascites and oedema	1
Fulminating bronchiolitis and acute congestive heart-failure	1
Steroid oedema	1
Total	22

Method

By an "acute" experiment we mean a study on the effect of a single oral dose of chlorothiazide 2 g

The patient's urine was collected for twenty-four hours up to 9 A M on the day of the test At 9 A M he was given chlorothiazide 2 g, and the next twenty-four hours' excretion of urine was collected in two amounts—a six-hour fraction from 9 A M to 3 P M, and an eighteen-hour fraction from 3 P.M to 9 A M Each sample of urine was measured, its pH recorded, and its Na, Cl, and K concentration estimated Samples of blood were taken at the end of each collection period and their protein, urea, Na, K, Cl, and alkali reserve were estimated Urinary bicarbonate was not measured, but it can be approximately calculated from the Na, K, and Cl values, since phosphate, the other important anion, is excreted in small and only slightly varying amounts (Ford et al 1958) Sodium and potassium were measured by flame photometry, chloride by mercuric-nitrate titration (Schales and Schales 1941), and alkali reserve by the gas volumetric method (Van Slyke and Cullen 1917) Urea was estimated by the method described by King (1951), and serum-protein by the biuret method (Gornall et al 1949), and pH of urine with narrow-range indicator paper (British Drug Houses)

Results

Table I gives the average hourly excretion-rates of urine and electrolytes (in all except the last 2 cases) for the twenty-four hours before the administration of chlorothiazide (period I), the next six hours (period II), and the subsequent eighteen hours (period III)

Clearly there is a considerable increase in the flow of urine, which is greater in the six hours immediately after the administration of chlorothiazide This is associated with an increased output of electrolytes—sodium, chloride, bicarbonate, and potassium in that order of magnitude In the main there was little alteration in the serum-electrolytes The serum-urea level was altered in only 1 patient, who had chronic nephritis after a considerable diuresis it rose from 146 to 236 mg per 100 ml

Other points of interest are most easily considered in brief analyses of the different clinical groups

Congestive Heart-failure

8 of the 9 patients conformed to the general diuretic pattern. The findings in the remaining patient are of special interest and are detailed in table II, which shows that, before the administration of chlorothiazide, she was in a state of moderately severe depletion of sodium and chloride In spite of this she had a satisfactory diuresis with only minimal excretion of electrolyte Fig 1, which should be compared with table I, shows this discrepancy more clearly The explanation of this apparent water diuresis is obscure (nor can the increase in the alkali reserve be readily explained) Possibly chlorothiazide may interfere with the action of antidiuretic hormone (A D H) or its release from the posterior lobe of the pituitary gland

Cor Pulmonale with Cardiac Œdema

Although chlorothiazide increased the output of urine in each of these 3 patients, in only 1 was there a satisfactory diuresis In this patient it was associated with an almost equal output of chloride and bicarbonate during the first six hours (15 3 and 12 2 m Eq per hour respectively) In spite of increased bicarbonate loss the alkali reserve increased from a pre-chlorothiazide level of 32 5 m Eq per 100 ml to 36 0 m.Eq per 100 ml

The generally poor diuretic response of this group cannot be attributed either to a deficiency of serum-electrolytes or to poor glomerular filtration, because the serum-urea levels were also normal Our experience with these 3 patients supports our clinical impression that special factors contribute to the mechanism of fluid retention in patients with chronic bronchitis and right heart-failure.

Pre-eclamptic Toxæmia

In all 3 patients there was a substantial diuresis during the six hours after the administration of chlorothiazide In each it was considerably greater than the series mean (201 7, 181 7,

II	28	116	4 4	87	28	740	15	22 0	37	5 9
III	23	116	4 7	85	36	1850	24	24 0	52	—
										HCO_3 (m Eq)
I	Hourly excretion-rate					18 4	0 07	0 42	0 40	0 09
II						123 3	1 85	2 70	1 52	3 02
III						102 6	2 47	2 47	5 15	0

and 201 7 ml an hour) It decreased rapidly to average values during the next eighteen hours In 2 patients the electrolyte excretion conformed to the usual pattern, but in the 3rd patient the excretion of K and HCO_3 was greater than average during the period of maximum diuresis (17 00 and 12 23 m Eq per hour respectively) No significant fall in blood-pressure was noticed during or immediately after the acute experiment

Renal Disease

We performed 3 acute experiments on a patient with nephrosis The pattern of urinary excretion of electrolytes was roughly the same in each During the first study, however, the urinary excretion of Na and HCO_3 increased to the very high values of 63 41 and 46 69 m Eq per hour respectively This was the only occasion on which we observed side-effects—namely, marked weakness Though this seems to have been due to the massive loss of sodium rather than potassium, the levels of these ions in the serum altered little and remained within normal limits (Na 134 m Eq per 100 ml each time, K 3 9–4 6 m Eq per 100 ml)

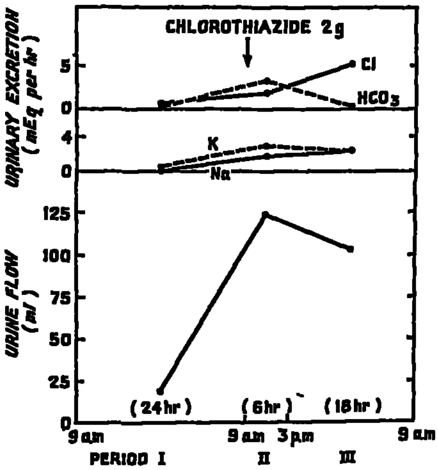

Fig 1—Congestive heart-failure, showing substantial diuresis associated with very low excretion of electrolytes

We studied 1 case of chronic nephritis in the terminal phase Although the patient was severely acidotic (alkali reserve 18 m Eq per 100 ml), the substantial diuresis which occurred was associated with a considerable output of HCO_3, with the result that the alkali reserve decreased to 14 m Eq per 100 ml by the end of period II Then, in spite of continuing excretion of bicarbonate, the alkali reserve increased to 21 m Eq per 100 ml by the end of period III This was the only patient in whom the serum-urea level rose (from 146 to 236 mg per 100 ml)

Hypertension

2 cases were studied A woman with no evidence of œdema, heart-failure, or renal disease, obtained an excellent diuresis (227 5 and 111 5 ml per hour during periods II and III respectively) associated with the usual pattern of excretion of electrolytes The other patient, who had left heart-failure with pulmonary congestion, albuminuria, and moderate uræmia (blood-urea 110 mg per 100 ml) gave no response She was hypochloræmic (88 m Eq per 100 ml), but the other serum electrolyte levels were normal Poor glomerular filtration may have been the adverse factor here

Hepatic Cirrhosis

After the first dose of chlorothiazide this patient had a diuresis of 3 5 litres in twenty-four hours, and the abdominal girth at the umbilicus decreased by 2 inches The detailed experimental results of the second dose given a week later are shown in fig 2 There are two features of interest (1) a good diuresis during period II without a corresponding increase in the excretion of electrolytes, and (2) a sustained diuresis during period III associated with considerably increased excretion of sodium and chloride The following explanations for this unusual type of response seem worthy of consideration the diuresis in period II may be another example of mainly "water diuresis", while the prolonged augmented response in period III may reflect delayed absorption or impaired metabolism of chlorothiazide due to the underlying liver disease

Although serum-potassium levels were low (3 2–3 5 m Eq per 100 ml), no symptoms of hypokalæmia arose, and it is noteworthy that potassium excretion was negligible

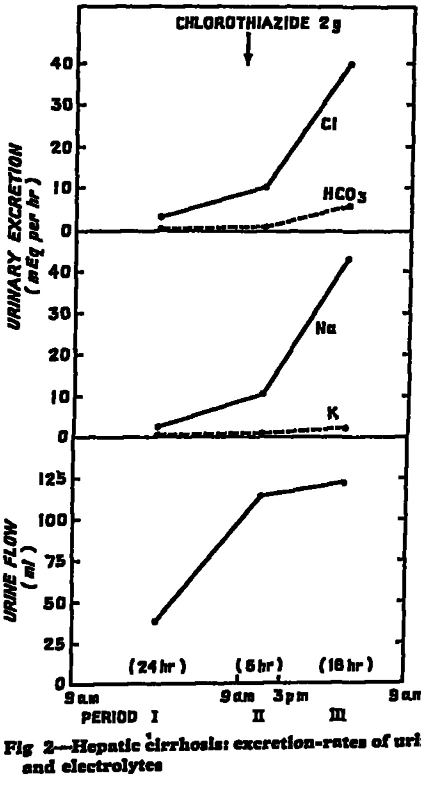

Fig 2—Hepatic cirrhosis: excretion-rates of urine and electrolytes

Steroid Œdema

This patient, in the sixth month of pregnancy and receiving cortisone 150 mg daily to prevent erythroblastosis fœtalis, developed puffiness of her face Chlorothiazide produced a diuresis of 3 37 litres in twenty-four hours with a proportionate loss of all electrolytes, there was no significant change in the serum-electrolyte levels

Bronchiolitis and Heart-failure

The last case was a young man, with acute fulminating bronchiolitis and toxic myocarditis, in a state of hypochloræmic alkalosis (Cl 84 m Eq per 100 ml , alkali reserve 40 m Eq per 100 ml) In period II the volume of urine was 83 3 ml per hour, compared with 7 6 ml per hour in period I This moderate diuresis was associated with minimal excretion of Na and Cl (1 67 and 2 00 m Eq per hour respectively) and proportionately greater excretion of K and HCO_3 (6 33 and 6·00 m Eq per hour respectively) During period III the patient became incontinent and further study of his urine was impossible

Discussion

The diuresis which occurs after the administration of chlorothiazide is associated chiefly with an increased excretion of sodium and chloride When the serum levels of these electrolytes are low, the drug will not compel their excretion in such circumstances it tends to promote the excretion of potassium and bicarbonate Hypochloræmia can easily be corrected, however, by administering ammonium chloride, and this simple expedient might augment the diuretic action of chlorothiazide in such patients as it augments the action of mersalyl

In 2 of our cases a significant amount of bicarbonate was lost in the presence of a low alkali reserve In 3 others moderate loss of bicarbonate was associated with an increasing alkali reserve We have seen a satisfactory diuresis in the absence of a corresponding electrolyte loss and we wonder if this denotes an anti-A D H activity of chlorothiazide

In general the best diuretic response occurred in the type of patient who responds well to mersalyl In patients with pulmonary heart-disease the response was disappointing After six months' experience with chlorothiazide we are not certain that tolerance develops, nor are we convinced that a regimen of divided doses (i e , 1 0 g b d) has any clinical advantages We feel that, unless there are urgent reasons for obtaining a maximal diuresis, single doses are preferable because they avoid the fatigue of unnecessary nocturia

Summary

The clinical and biochemical effects of a single dose of chlorothiazide 2 g given to each of 22 patients with various " water-retaining " conditions are reported

Chlorothiazide is an effective and safe oral diuretic which acts principally by promoting excretion of sodium and chloride but in certain circumstances by promoting excretion of potassium and bicarbonate Occasionally it may produce a water diuresis

Certain practical aspects of its use are discussed

Chlorothiazide was supplied by Messrs Merck, Sharp, and Dohme

THE DEVELOPMENT OF THE NIPPLE IN PREGNANCY

F E HYTTEN
M B Sydney, Ph D Aberd

DUGALD BAIRD
M D , B Sc Glasg , F R C O G , D P H

MEMBERS OF THE OBSTETRIC MEDICINE RESEARCH UNIT (MEDICAL RESEARCH COUNCIL), MIDWIFERY DEPARTMENT, UNIVERSITY OF ABERDEEN

IT is widely believed that many women have nipples which require active treatment during pregnancy to make them suitable for breast-feeding

This opinion was first made popular by Waller (1939), who subsequently described a test for the detection of defective nipples " In imitation of the action of the baby's jaws the areola is pinched [by the thumb and forefinger] just beyond the nipple's base ", if the nipple projects when this is done it is considered to be " protractile " and therefore satisfactory (Waller 1946)

Of 200 primigravidæ examined by Waller 56 had " poor protraction ", 95 " moderate protraction ", and only 49 " good protraction "

On a similar basis Blaikley et al (1953) thought that 52 of 234 primigravidæ had nipples which required antenatal treatment because they were "poorly protractile", and Naish (1948) stated that " retracted nipples and nipples poorly formed are a common abnormality " requiring treatment early in pregnancy

Manual expression of colostrum, manipulation of the nipple, and the wearing of nipple shields during the last three months of pregnancy are claimed by both Waller and by Blaikley et al to give excellent results

A defective nipple, from the functional point of view, is one which hinders suckling, and on this basis the incidence of poor nipples is very much smaller than when they are arbitrarily assessed in early pregnancy

In Aberdeen, for example, where there is seldom any antenatal treatment of the nipples, only 4 3% of 2461 first babies had any difficulty in fixing owing to poor nipples, and only 2 5% had to be weaned for this reason (Hytten 1954)

Spence (1938) also considered poor nipples to be a minor cause of feeding difficulty

This suggests either that the clinical assessment of nipples early in pregnancy is unreliable or that many " poor " nipples improve spontaneously during pregnancy Clearly the value of antenatal treatment of the nipples could only be assessed if a matched control group receiving no treatment were studied at the same time

Some doubt has been cast on the value of preparing the breasts during pregnancy

Stone (1946) says " Preparation for the act of nursing begins during pregnancy chiefly by avoiding most of the local manipulations and applications which are so widely and indiscriminately advocated "

The Ministry of Health (1943) goes further, discussing why some women dislike breast-feeding " In some cases this distaste may have been engendered by an unnecessarily elaborate routine prescribed during the antenatal period. It is, we fear, bordering on the paradoxical to impress upon the ordinary expectant mother that breast feeding is a normal, easy and natural process, if at the same time the advice she receives as a routine imposes on her the need for an elaborate daily ritual of preparation We think it possible that with an anxious type of woman too much insistence on preparation of the breasts may alarm and discourage her to such an extent that she will refuse to initiate breast feeding "

Cummane (1938) made the same point.

The present investigation was planned to assess the changes which take place in the nipple during pregnancy,

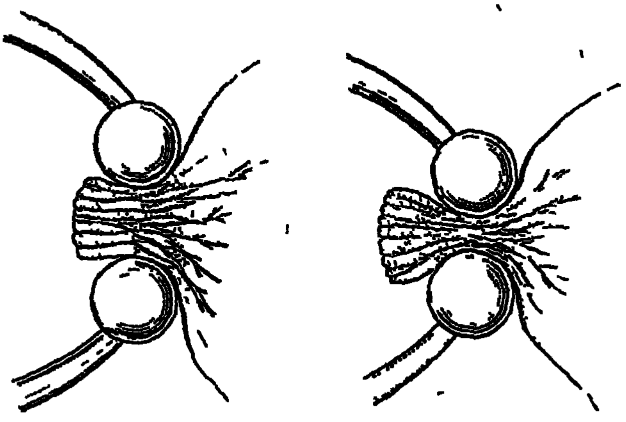

Fig 1—Measurement of " bite ", showing how tissue behind nipple is compressed

and to define more accurately the incidence of unsatisfactory nipples

Material and Methods

Material—Clinical assessments and measurements of the nipple and areola (see below) were made in 170 primigravidæ and 104 multigravidæ at their first visit to the antenatal clinic between the 8th and 15th weeks of pregnancy, and repeated at subsequent visits to the clinic and on the 1st postpartum day Only women booking at the clinic later than the 15th week of pregnancy were excluded, there was no other conscious selection All measurements and assessments were made by one staff midwife No antenatal preparation or treatment of nipples was undertaken

Methods of Assessment—" Protractility " was estimated by pinching the areola between the thumb and forefinger in the manner described by Waller (1946) An attempt was also made to assess the ability of the nipples to become erect, but the response seemed to depend to a large extent on factors such as air temperature and could not be reliably elicited by manipulation After clinical examination three measurements were made (1) the diameter of the areola, (2) the diameter of the nipple, and (3) the " bite "—the minimal thickness of tissue behind the nipple The last was measured by compressing the areola immediately behind the nipple in the position where the baby makes its grip for suckling, with ¼-inch diameter ball-ended callipers to a point just short of discomfort for the mother * (fig 1)

Follow-up—The breast-feeding performance of each woman was closely observed in hospital, and difficulties were noted in detail

Clinical Findings

Of the 170 primigravidæ whose nipples were tested by Waller's method 59 (34 7%) showed at least some evidence of poor protraction in early pregnancy, the incidence was not related to maternal age Gradual improvement took place during pregnancy, and by the puerperium the number was reduced to 13 (7 7%), however, the nipples of 1 woman were protractile in early pregnancy but deteriorated progressively and became retractile by the puerperium

Of the 170 primigravidæ 11 experienced difficulty in feeding, wholly or partly owing to the inability of the baby to fix to the nipples, and 7 of them had to abandon breast-feeding 6 of these were from the 13 women whose nipples remained poorly protractile throughout pregnancy (3 gave up breast-feeding), a 7th was the woman whose nipples deteriorated during pregnancy, and the remaining 4 had normally protractile nipples

Thus, of the 59 women who showed poor protraction in early pregnancy about 10% eventually had difficulty in suckling, and 5% abandoned breast-feeding at least partly for this reason, of the 111 other women whose nipples were clinically normal in early pregnancy about 4 5% had difficulty and about 3 5% gave up for this reason

Of 75 women with second babies only 8 (10 5%) had poorly protractile nipples in early pregnancy, in 3 this persisted after delivery, and in 2 of them there was difficulty in fixing None of 29 women with a third or later child had poor nipples or difficulty in fixing

It was seldom possible to predict which nipples would cause difficulty in feeding, because success or failure in suckling depends very largely on the efficiency of the baby For example, in 3 instances where the nipples were protractile but smaller than average there was considerable difficulty because the baby was lethargic, on the other hand, in several cases nipples which by Waller's definition would be classified as poor caused no difficulty, because the baby sucked vigorously

Measurements

Diameter of Areola

The diameter of the areola increased progressively throughout pregnancy For primigravidæ the mean increase from 34 mm in early pregnancy to 50 mm in the early puerperium was approximately linear, but some records showed irregularity because of such influences as contraction of the areola owing to cold Multigravidæ showed a similar increase from about 36 mm to 52 mm

For primigravidæ the average increase in the diameter of the areola was less as maternal age increased (table I), but there was no age gradient for multigravidæ

Diameter of Nipple

The diameter of the nipple cannot be measured exactly, because it varies with the degree of erection There is no doubt, however, that the diameter increases during pregnancy from a mean of about 9 5 mm to 11 5 mm in primigravidæ and from about 10 mm to 12 5 mm in multigravidæ There are no obvious differences due to age

" Bite "

The measurement of " bite " may be regarded as a quantitative assessment of the protractility of the nipple because, in the case of a nipple which will not pull forward, the calliper ends cannot be approximated and will therefore register a large " bite ", conversely, the nipple which is easily mobile has loose readily-compressed tissue behind it and therefore a small " bite " Table II shows the relationship between the clinical assessment of protraction and the " bite " at the first antenatal visit Almost

TABLE I—EFFECT OF AGE IN PRIMIGRAVIDÆ ON INCREASE OF AREOLAR DIAMETER DURING PREGNANCY

Maternal age (yr)	No of subjects	Mean diameter of areola (mm) 8–15 wk of pregnancy	Early puerperium	Increase %
15–19	14	35 8	58 4	63
20–24	90	34 0	51 6	52
25–29	48	34 0	48 5	43
30+	18	33 0	44 2	34

The decreasing response with increasing age is statistically significant

---

* Spring-loaded callipers were used in the early stages of the experiment in an attempt to ensure complete objectivity of measurement, but no single spring pressure was universally suitable—for example, a very powerful spring was needed in some women to give the degree of compression comfortably obtained by the hand callipers, and this pressure caused pain to other women

TABLE II—RELATIONSHIP BETWEEN CLINICAL ASSESSMENT OF NIPPLE PROTRACTION AND SIZE OF "BITE" IN 170 PRIMIGRAVIDÆ IN EARLY PREGNANCY

—	Bite' (mm)				
	1–2	3–4	5–6	7–8	9–10
No of subjects	11	56	71	30	2
No having poorly protractile nipples	0	0	32 (*45%*)	25 (*83%*)	2 (*100%*)

all nipples which had a "bite" of more than 6 mm were considered clinically to be unsatisfactory, when the "bite" was 6 mm, about half the nipples were poorly protractile, and all nipples with a "bite" of 4 mm or less were clinically satisfactory

Usually the "bite" decreased during pregnancy Fig 2 shows the change in the distribution of the measurement between early pregnancy and the puerperium for the 170 primigravidæ In early pregnancy about 40% had measurements of 4 mm or less, by the puerperium this proportion had risen to almost 80%

Of the 103 (about 60%) who had a "bite" exceeding 4 mm in early pregnancy, in 83 the "bite" had decreased to 4 mm. or less at delivery, and 6 others, in which the "bite" was initially small, showed an increase to 6 mm or more Of these 26 women in whom the postpartum "bite" of the nipples measured 6 mm or more 9 had difficulty in feeding because of inability to fix, of the 144 women in whom the postpartum "bite" was less than 6 mm there was difficulty in fixing in 4

In multigravidæ the mean "bite" was initially much smaller than for primigravidæ, and the improvement during pregnancy was less striking The proportion with a "bite" of 4 mm or less was about 70% in early pregnancy and increased to 83% in the puerperium Of the 104 multigravidæ 32 had a "bite" measuring more than 4 mm in early pregnancy, and in 10 of these the "bite" was still more than 4 mm after delivery, they caused difficulty in feeding in only 1 case In 5 others the "bite" increased from 4 mm in early pregnancy to 6 mm or more, but there was no trouble in feeding

Maternal age had no obvious effect on the measurement of the "bite"

Discussion

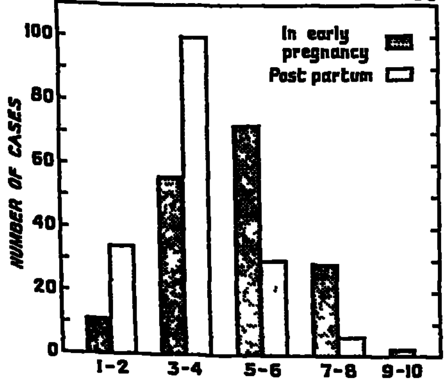

Fig 2—Distribution of size of "bite" in 170 primigravidæ in early pregnancy and postpartum

Waller's method of assessing the nipple has some predictive value because poor protraction in early pregnancy doubles the risk of difficulty in "fixing" during lactation, but it is of little value in the individual case, because 9 out of 10 women whose nipples show poor protraction early in pregnancy have no difficulty with fixing, largely because their nipples have become normally protractile by the end of pregnancy Since about a third of our primigravidæ were judged to have poorly protractile nipples in early pregnancy and Waller (1950) states that the test "reveals in rather more than a third of our patients in their first pregnancy enough defect in one or both nipples to threaten difficulty", it is reasonable to assume that our standard of assement is comparable with his Our findings are also in broad agreement with those of Blaikley et al (1953), who considered 20% of 234 primigravidæ to be in need of treatment

Waller states that at least some improvement can be expected from treatment "in all but a few", and Blaikley et al claimed "complete correction" or "good improvement" in 49 of their 52 women with poorly protractile nipples, but in neither paper was the state of the nipple at the end of pregnancy correlated directly with the actual feeding performance The fact that in our subjects just as much improvement took place in the development of all but a few nipples without treatment suggests that the changes they undergo during pregnancy, which make them more suitable for breast-feeding, are physiological and not the result of treatment

If this is so, treatment should be reserved for the small group of primigravidæ whose nipples remain poorly protractile throughout pregnancy, but there is no test which can be used early in pregnancy to differentiate them from those cases in which improvement will take place spontaneously as pregnancy progresses Such cases may constitute the small group which both Waller and Blaikley found to be resistant to treatment

The changes in the nipple brought about by pregnancy seem to be cumulative, hence a woman starts her second pregnancy with better-developed nipples than she had early in her first pregnancy After three or more pregnancies a nipple rarely gives any trouble in feeding or fails any test which might be applied to it Epidemiological studies of breast-feeding performance confirm this—for example, 4 3% of 2461 Aberdeen primiparæ experienced feeding difficulty due to unsatisfactory nipples, but only 1 7% of 3995 multiparæ had trouble of this kind, and within this group the incidence of difficulty decreased as parity increased (Hytten 1954) Clearly the influence of parity must be taken into account in assessing the effects of treatment

Naish (1948) instanced women who had been unable to breast feed their first baby because of unsatisfactory nipples but managed to feed their second babies after treatment, but improvement between first and second pregnancies is to be expected in more than half such cases even without treatment

Apart from its effect on the area of the areola, shown in table II, maternal age seems to have no important influence on the development of the nipples, and this is in keeping with the observation that the incidence of difficulty in breast-feeding due to poor nipples is uninfluenced by age (Hytten 1954) By contrast, there is a strong correlation between age and the development of the secretory breast tissue (Hytten, unpublished), the difference may be explained by the fact that the development of secretory breast tissue in pregnancy is one of growth, whereas the most important changes in the nipples are those which give it greater mobility, growth per se being relatively unimportant Increasing maternal age presumably affects this process of mobilisation much less than it affects cell proliferation

In view of the changes in the nipple which we have found during pregnancy, routine antenatal preparation of the breasts and nipples seems to be unnecessary Whether the small group of women whose nipples do not undergo the usual physiological changes would benefit from the types of local treatment usually advocated is doubtful The effectiveness of treatment could be assessed only by a closely controlled trial on a sufficient scale

Summary

The nipples of 170 primigravidæ and 104 multigravidæ were studied clinically and by measurement from early pregnancy until the puerperium No antenatal treatment was given to "defective" nipples

The nipples of about a third of the primigravidæ were judged to be defective, on grounds of retraction or poor protraction, in early pregnancy, but only about 8% were judged to have defective nipples in the puerperium In second pregnancies the proportions were 10% in early pregnancy and 4% in the puerperium In third and subsequent pregnancies none of the women examined had defective nipples These changes in the nipple were confirmed by measurement

The assessment of nipples in early pregnancy gives limited help in predicting which women will experience difficulty with breast-feeding due to inadequacy of the nipples This kind of difficulty with breast-feeding is, in any case, relatively uncommon, it affects less than 5% of primigravidæ and less than 2% of multiparæ who start breast-feeding

The value of routine "preparation" of breasts and nipples during pregnancy, with a view to improving prospects for breast-feeding, is dubious, and the anatomical improvements claimed for such treatment are probably due, in most women, to normal physiological changes during pregnancy

We are grateful to Staff Nurse C Mearns and to our colleagues in the Aberdeen Maternity Hospital and Midwifery Department of the University of Aberdeen for invaluable help with the investigation

COMBINED GASTROSCOPY AND GASTRIC BIOPSY UNDER DIRECT VISION

P E THOMPSON HANCOCK
M B Cantab , F R C P
SENIOR PHYSICIAN, ROYAL MARSDEN HOSPITAL AND INSTITUTE OF CANCER RESEARCH, ROYAL CANCER HOSPITAL, LONDON, S W 3, PHYSICIAN, ROYAL FREE HOSPITAL, LONDON, W C 1

MARGOT SHINER
M R C S , D C H*
RESEARCH ASSISTANT, DEPARTMENT OF GASTROENTEROLOGY, CENTRAL MIDDLESEX HOSPITAL, LONDON, N W 10

EVERY gastroscopist experiences uncertainty of the nature of the lesion which he finds For this reason attempts at biopsy of the gastric mucosa under direct vision were made by Benedict (1948), who attached biopsy forceps to Schindler's flexible gastroscope, and by Tomenius (1952) using suction biopsy with the same kind of gastroscope Both methods have their disadvantages With Benedict's forceps there is uncertainty of the depth of biopsy taken, and with Tomenius' method biopsy cannot be done under direct vision, because there is a distance of about 4 cm between the viewing lens of the gastroscope and the biopsy aperture, necessitating withdrawal of the instrument by that same amount

In an attempt to obtain better visual control of gastric biopsy and to control the thickness of the mucosal specimen Wood's gastric biopsy tube was modified to fit the Hermon Taylor gastroscope, as described by Shiner (1956), and has since been further modified, as described below We have successfully done 53 biopsies and discuss here the method of biopsy, its applications, and its difficulties

The Instrument

The instrument (fig 1) consists of the Hermon Taylor gastroscope fitted with an adjustable focusing eyepiece and carrying the modified Wood's gastric biopsy tube on its anterior surface This consists of a hollow plastic tube 62 5 cm long and 3 0 mm in diameter The biopsy head at its distal end has an oval aperture measuring 3 5 mm × 2 5 mm The position of the biopsy aperture is identified by a black cross, which is directly opposite its central point The biopsy knife is operated by scissor forceps at the proximal end, thus making it possible to open and close the biopsy aperture with one hand only A lateral exhaust at the proximal end serves for attachment of a manometer and a syringe to suck mucosa into the biopsy aperture at a known pressure The distal part of the biopsy tube runs in a tunnel formed by a hollow spiral tube covered with plastic material, the whole being attached to the gastroscope by an outer sheath 15 5 cm long The upper part of the biopsy tube is fixed to the gastroscope by two or three short rubber bands When retracted the headpiece rests on the rubber sheath of the gastroscope just below its point of emergence from the outer sheath (fig 2) The combined instrument assumes an oval shape with a diameter of 1 85 cm at its widest point

Its Application

Before introduction the instrument is thoroughly tested, particularly the up and down movement of the biopsy tube and knife, and the central position of the biopsy head in relation to the viewing lens The patient is prepared in the usual way for gastroscopy The instrument is introduced in the left lateral position with the greatest diameter in the transverse position of the pharynx and œsophagus After thorough inspection of the stomach the site of biopsy is chosen The biopsy tube is then pushed down so that the headpiece overlies the viewing lens (fig 3) It is rotated until the black cross appears in the centre of the field of vision The biopsy aperture then faces the gastric wall By flexing the gastroscope towards the site of biopsy the headpiece is approximated to the mucosa The biopsy knife is then operated with the scissor forceps to open the aperture, the manometer and syringe are fixed, and suction is applied to register a steady negative pressure of 15–20 inches *Hg* This may only be achieved by exhausting, through the syringe, some of the air previously introduced The pressure is maintained while the scissor forceps are closed, thus securing a specimen within the biopsy tube

Two or three biopsies may be obtained by this method After each biopsy the tube is withdrawn to its resting position, and the biopsy site is inspected, slight oozing can usually be seen coming from it The whole instrument is subsequently withdrawn

Results

The 67 patients subjected to this procedure were drawn mainly from outpatients One of us (P E T H), who has done more than 3000 gastroscopies, used the combined instrument on 57 patients presenting consecutively

---

* In receipt of a grant from the Medical Research Council

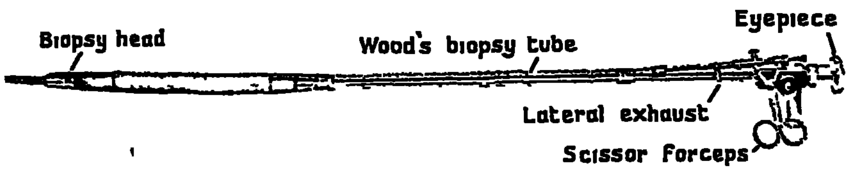

Fig 1—Combined Hermon Taylor gastroscope and biopsy instrument

for gastroscopy Neither difficulties in introduction nor complications were encountered in any of the patients, who were carefully questioned about the amount of discomfort, this was judged about equal to that experienced in ordinary gastroscopy In 6 cases the gastroscope could not be passed beyond the cardia, in 2 patients this was due to neoplastic infiltration around the cardia Once the cardia was passed, the view and rotating property of the gastroscope were undisturbed After biopsy the amount of bleeding was slight, frank hæmorrhage did not occur in any of the patients

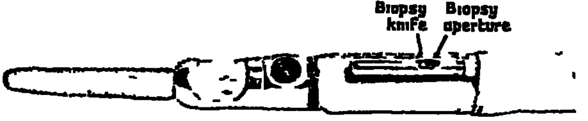

Fig 2—Distal end of instrument showing biopsy head in position of rest, and aperture partly open

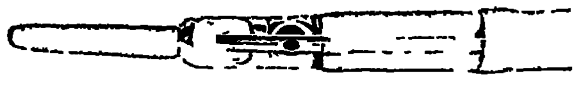

Fig 3—Biopsy head overlying viewing lens (black cross opposite biopsy aperture not shown)

The accuracy with which a specimen could be obtained by biopsy was found to be a matter of experience in handling the instrument This was also true regarding the number of failures at biopsy At only 53 of 60 attempted biopsies were specimens obtained In the second half of the series it was rare not to obtain a satisfactory biopsy specimen

During the trial it was found necessary to enlarge and modify the biopsy aperture because the amount of fragmentation of the earlier specimens was excessive, and it was doubtful whether a hard neoplastic mucosal lesion could be sucked into an aperture only 2 5 mm in diameter By changing the size and shape of the aperture as described the specimens taken were larger and less fragmented They contained full-thickness mucosa, muscularis mucosæ, and often a little submucosa (fig 4) Up to date we have obtained biopsy specimens of two carcinomatous lesions of the stomach, both radiologically negative but subsequently confirmed by operation In the later specimens all layers were well preserved, enabling detailed histological studies to be made This is important both from the diagnostic and from the research point of view

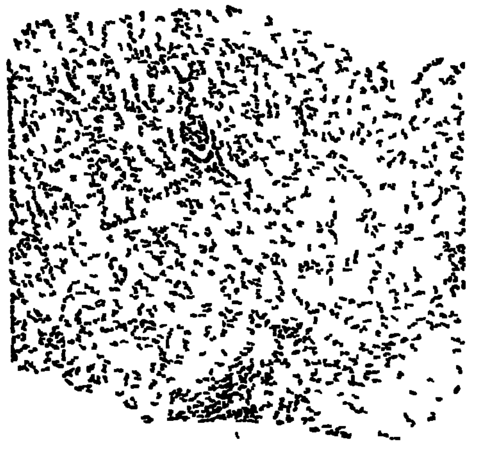

Fig 4—Biopsy specimen of normal gastric mucosa showing full-thickness mucosa, muscularis mucosæ, and some submucosa (Hæmatoxylin and eosin ×21)

Discussion

It is our view that the combined gastroscope-biopsy instrument offers great scope for more accurate diagnosis of gastric pathology With Benedict (1950), Shallenberger et al (1950), and Wirts et al (1951) we feel that the instrument can be used with safety in any patient in whom it is possible to perform gastroscopy, in our case using a modified Hermon Taylor gastroscope

At present it is too early to state that a biopsy specimen can always be obtained from an ulcer margin with accuracy, and that a neoplastic lesion can always be sucked into the biopsy aperture. Further, biopsy is confined to areas within reach of the gastroscope, which in many cases excludes the antrum Wirts et al (1951) found that with the Benedict type of operating gastroscope they were usually unable to obtain biopsy specimens from lesions high on the lesser curvature We have not encountered this difficulty

The same workers also mentioned the disadvantage of the reduced angle of vision in the objective of the operating gastroscope Both these objections have been overcome by using the Hermon Taylor type of gastroscope and Wood's gastric biopsy tube with its lateral aperture

Wirst et al found the increased diameter of the combined gastroscope more distressing to their patients, and rotation of the instrument into the anteroposterior position more difficult This has not been our experience

But with these workers we agree that it is difficult to keep the patient's stomach adequately inflated, because the air tends to escape through the cardia more easily

Incidentally Wirts et al mention that the use of Wood's gastric-biopsy-tube attachment would have possible advantage over the Benedict's forceps—a suggestion of which we were not aware when first experimenting with the instrument

Summary

A method of combined gastroscopy and biopsy under direct vision is described

60 patients have been biopsied up to date without any complications

We wish to thank Mr G Hawkins, of the Genito-Urinary Manufacturing Company, for his unfailing help in developing the biopsy gastroscope, Dr N F C Gowing, of the department of morbid anatomy, Royal Marsden Hospital, for much of the pathological work and for the photomicrograph, and our colleagues at both hospitals for referring their patients to us

Preliminary Communications

PORTAL BACTERÆMIA IN ULCERATIVE COLITIS

JAUNDICE has, in our experience, occasionally complicated colonic excision for ulcerative colitis, developing within 48 hours after operation, full investigation failed to disclose hæmolysis as a result of blood-transfusions in any case This jaundice lasts for one or two days and invariably clears Its cause remained a mystery until the following case was seen recently

A man, aged 28, who had had an ileostomy instituted 8 years before, was submitted to panproctocolectomy 48 hours after this operation which was uneventful, his temperature rose with rigors to 106 5°F and he became jaundiced After 10 days his jaundice had subsided, though at the 5th postoperative day serum-bilirubin had reached 21 mg per 100 ml

The rigors and pyrexia in this case suggested the possibility of an infective cause for the jaundice Frank portal pyæmia seemed unlikely since jaundice had cleared spontaneously in all cases without antibiotic treatment, moreover, liver abscesses have not been found in any case of ulcerative colitis Portal bacteræmia was a possible explanation since the condition of the bowel would favour bacterial invasion of the colonic veins, thus leading to hepatitis without abscess formation since the hepatic reticulo-endothelial cells might be able to assimilate organisms though not septic emboli The following pilot investigation was therefore undertaken to ascertain whether bacteria invade the portal stream

METHOD

Controls had to be devised to eliminate the possibility that organisms may escape into the portal blood under normal circumstances and, further, when the intestines are handled at laparotomy Two samples of portal blood were therefore taken, one on opening the abdomen and the other at an advanced stage of the operation when the intestine had been manipulated Two control groups were chosen, one comprising patients with no lesion of the large bowel, and the second patients with a colonic lesion other than ulcerative colitis (table I)

Blood samples were obtained from veins draining the transverse colon in the first control group, and from veins near the lesions in the second control and the colitis groups It is easier to obtain blood by needle and syringe from a peripheral systemic vein than from a portal radical, for the vessel is less well supported in the mesentery and it is not possible to obstruct the venous return satisfactorily there while taking the sample We have found it most satisfactory to attach needle to syringe by a few inches of rubber tubing, one person then inserts the needle and holds it in place while another slowly withdraws the plunger

TABLE I—BACTERIOLOGICAL FINDINGS IN PORTAL BLOOD IN TWO CONTROL GROUPS

Group no	Case no	Sex	Diagnosis	Specimen no	
				1*	2†
1	1	M	Anastomotic ulcer	0	0
„	2	F	Gallstones, cholecystitis	Staph	Staph

„	15	F	Carcinoma of cæcum	0	0

* Taken before handling gut † Taken after handling gut

Synchronous samples of systemic blood were not taken at the outset, but only after positive portal-blood cultures had been obtained for the first time and it was realised that these results might be open to attribution to generalised septicæmia unless bacteriological evidence to support the contrary clinical assessment was forthcoming

RESULTS

Tables I and II show the results

Controls (table I)

From only 1 of the control series, a case of cholecystitis, were organisms grown, these were non-pathogenic staphylococci

Ulcerative Colitis (table II)

Organisms were grown from 4 of the 9 cases of ulcerative colits—from 1 case (case 16) on two separate occasions, at primary colectomy and again six months later when the rectum was excised

DISCUSSION

In control case 2 (cholecystitis), where organisms were grown, these may have been contaminants, but this seems unlikely, since the blood samples could hardly have been taken under more aseptic conditions Moreover each blood sample was divided among five separate cultures, three from the first sample and two from the second being positive Chance contamination would hardly yield such profusion Schatten et al[1] reported portal pyæmia in 8 cases of a series of 25 with intra-abdominal lesions, none affecting the colon, staphylococci were cultured in

TABLE II—POSITIVE BACTERIOLOGICAL FINDINGS IN PORTAL BLOOD IN CASES OF ULCERATIVE COLITIS

Case no	Sex	Operation	Specimen no		Evidence of systemic infection	Comment
			1*	2†		
16	M	Colectomy	*Ps pyocyanea, Bact acidi-lactici Strep intermedius*	As in (1) plus *Cl welchii*	No blood culture No clinical evidence	—
		Rectal excision 6 mos later	*Staph albus*	*Staph albus* plus paracolon bacillus	Systemic blood at time of operation negative	—
17	F	Colectomy	*Esch coli*		No clinical signs of septicæmia before operation Blood-culture pos 3rd postoperative day, *Esch coli* grown but sensitivities different from portal-vein sample	1st sample from descending colon, 2nd sample from ileocæcal region, which was less seriously ulcerated
18	F	Panproctocolectomy		Paracolon bacillus, *Esch coli anaerogenes*	Systemic blood-culture at time of operation negative	—
19	M	Colectomy	Mixed staph	Pure *Staph albus*	Systemic blood culture at time of operation negative	Possibly contaminants

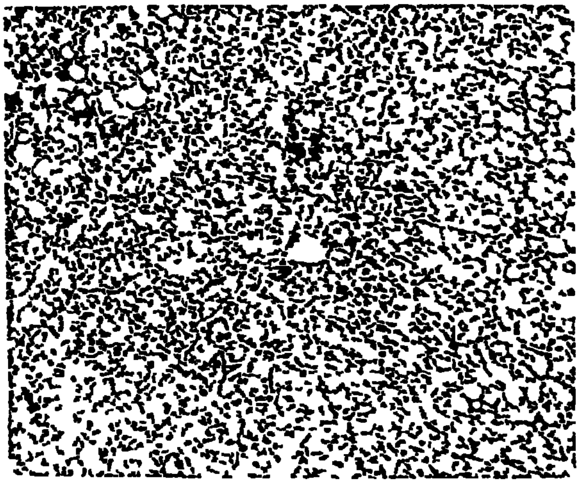

Fig 1—Case 2 section of liver showing peripheral lobular degeneration and fatty replacement

4 cases, all of cholecystitis That portal bacteræmia may arise spontaneously from time to time cannot therefore be ruled out

In 3 of the 4 present cases of ulcerative colitis where organisms were isolated from the portal blood, there can hardly be any question of this being due to contamination In the 4th case, where *Staphylococcus albus* was isolated, this is less certain Nevertheless this organism can be isolated from the bowel and may develop pathogenic qualities, in 1 case of ulcerative colitis previously reported,[2] generalised septicæmia due to *Staph albus* developed, and the patient died

The results in the first control group indicate that handling normal bowel does not produce a shower of organisms in the portal circulation, the same conclusion might be drawn from the second control group, but over half the patients in this group had carcinoma and in these cases every effort was therefore made not to handle the affected bowel In 1 case of the colitis group (case 17) organisms were discovered in the first sample but not the second, this may have been due to the fact that the second sample was taken from the right side, there the disease was less pronounced Operative manipulation seems to have increased the flora obtained at each of the 2 operations in case 16, and to have produced organisms for the first time in case 18

Could these results have been due to septicæmia or pyæmia? At 3 of the 5 operations (table II) systemic-blood samples taken synchronously with the first sample of portal vein blood were negative on culture, in neither of the 2 instances where systemic-blood samples were not taken did the patient show clinical signs of septicæmia at the time of operation, in 1 of these instances (case 17) the culture of systemic blood became positive for *Escherichia coli* three days after operation, but the sensitivities of this organism differed from those of the coliform organisms which had been grown from the first sample of portal blood Generalised septicæmia seems therefore to be an unlikely explanation of organisms isolated from the portal blood in these cases

Though jaundice did not develop in any of the 3, or possibly 4, cases of portal bacteræmia, severe liver damage was observed in the 2 cases where hepatic biopsy was undertaken, significantly, degeneration was pronounced at the periphery of the lobules—that is, in the vicinity of the afferent venules (fig 1) Fig 2 shows bowel wall with ulceration into the submucosal vascular plexus, the ulcer bed is highly vascular It is hardly surprising that it is in such cases, rather than those with relatively superficial ulceration in the mucosa, that organisms escape into the portal stream

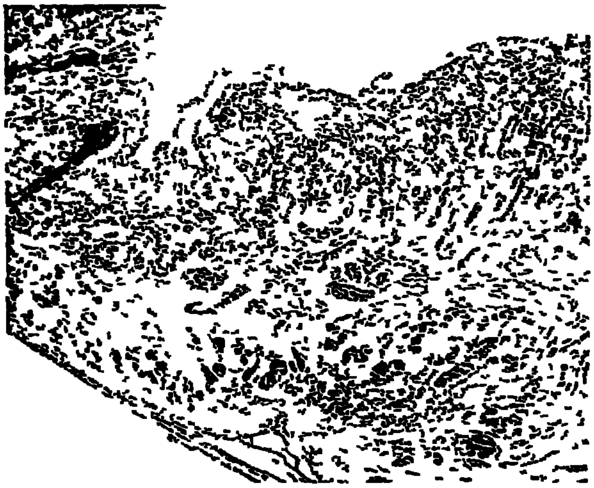

Fig 2—Case 1 ulceration has almost completely penetrated and destroyed muscle of colon wall, which is replaced by engorged vessels of granulation tissue

CONCLUSIONS

This pilot study indicates that portal bacteræmia may complicate certain colonic disorders, and in particular ulcerative colitis

We thank Dr M J Meynell and Dr H M Smallwood for their bacteriological investigations

THE OCULAR COMPLICATIONS OF CHLOROQUINE THERAPY

Visual disturbances due to synthetic antimalarial drugs have been known since Reese[1] and Chamberlain and Boles[2] reported corneal œdema in American airmen who complained of blurred vision and haloes while taking prophylactic mepacrine in suppressive doses Their cases were exceptional among the large numbers to whom the drug was administered in this way, and these workers regarded them as a manifestation of idiosyncrasy, producing only a transient corneal disturbance which disappeared as soon as the drug was withheld

A more durable effect on vision was noted by Ida Mann[3] in workers engaged in the manufacture of mepacrine and in whom the severe blurring of vision was absent, but in her cases haloes were apparent from a deposit in the superficial layers of the cornea which was seen by slit-lamp microscopy to consist of fine yellowish dots This she believed to arise from direct contamination of the cornea by the mepacrine dust in the atmosphere of the works, and it and the symptoms were seen to subside in the affected persons when they were withdrawn from this work

In recent years the efficacy of such drugs, particularly chloroquine, in the treatment of some other diseases

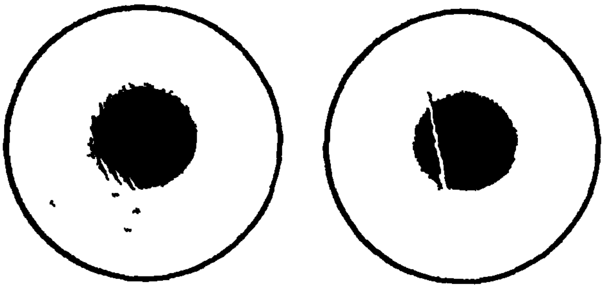

Fig 1—Lines of deposit in corneal epithelium (painting)

(notably lupus erythematosus and actinic dermatitis) has led to their empirical use in higher dosage, with which visual symptoms tend to develop more often Bleil[4] has reported from the United States the transient appearance of opacification of " the subepithelial layers and Bowman's zone " of the cornea, producing partial blindness as one of a group of severe symptoms in a patient under treatment with amodiaquine (' camoquin ') for lupus erythematosus, a finding which, from the description given, may be compared with the cases of corneal œdema reported by American workers in 1946 and referred to above

Here we draw attention to a more insidious and less transient condition resulting from the administration of chloroquine, it develops after an interval and on a dosage which shows considerable individual variation, it consists of visual disturbance associated with haloes suggesting congestive glaucoma and characteristic deposits in the corneal epithelium The details of the condition have been determined after the examination of 30 patients to whom chloroquine was being administered in various dosages and on different clinical indications 23 had lupus erythematosus, 4 actinic dermatitis, 1 chlorpromazine photosensitivity, 1 pityriasis lichenoides, and 1 infestation with *Clonorchis sinensis*, 28 of them were seen during or immediately after a course of treatment lasting from several weeks to two years To some degree these formed a selected group because, at the beginning of the investigation at least, they were those who complained of some disturbance

The 2 exceptions were both admitted for observation at the beginning of treatment so that early symptoms might be observed, we particularly wanted to know if epithelial œdema was an early change In both cases examination was negative, a finding which is perhaps of little value but may be correlated with the absence in the history of the other cases of any symptoms suggesting such a change in the early stages of treatment

Of the remaining 28 patients 19 complained of the following symptoms

	No of Cases
" Blurred " or " misty " vision	4
" Blurred vision and coloured rings round lights "	3
Focusing difficulties	3
' Sore eyes "	1
Various symptoms of drug intolerance*	8

* Described as photophobia, ' traffic dancing ', ' vision closing in ', " vision seemed not to register ', ' nausea and a drugged feeling ', &c

The spontaneous perception of haloes round lights was the presenting symptom in only 3 cases It was complained of by the patient who originally came to our attention and by only 2 others, and in all of them it occurred in special circumstances likely to demonstrate this diffraction effect—i e , while driving at night The appearance may be mimicked by causing the patient to view a naked light through a thin film of lycopodium powder, a test which is commonly used in ophthalmological practice to identify haloes of corneal origin, and when this was displayed to the patients under investigation 3 of them commented subsequently that they had become aware of seeing such haloes Although pathognomonic of such a corneal disturbance as is seen in these cases this symptom is clearly one which calls for a degree of perception which is not universal

Examination of these 28 patients by slit-lamp microscopy showed corneal changes in 22, but the apparent correspondence between this number and those complaining of symptoms is misleading because of the 9 cases who were asymptomatic 5 showed changes, severe in some of them, and among the 19 with symptoms no such changes were seen in 4 It is therefore evident that the complaint of some general visual disturbance is an unreliable guide

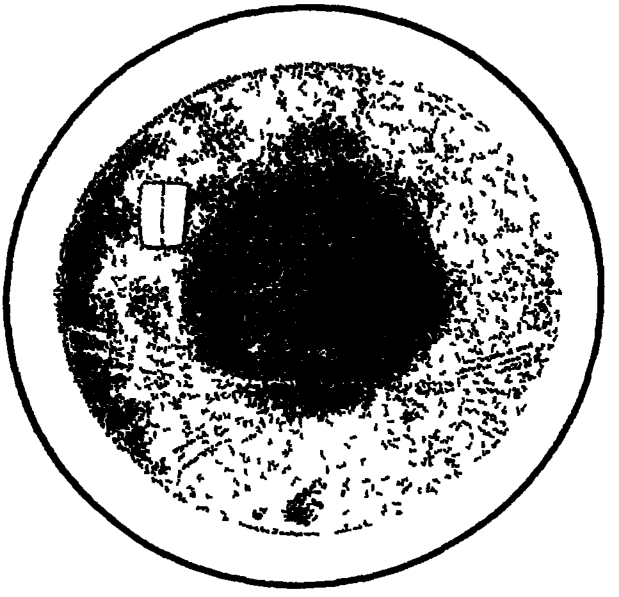

Fig 2—General epithelial deposit with incipient line formation (painting)

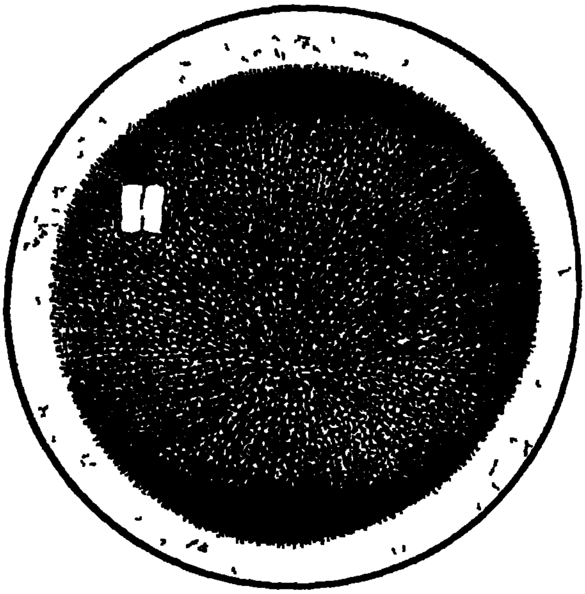

Fig 3—Severe general epithelial deposit (painting)

to the presence of the corneal changes which are characteristic in treatment with these drugs.

The changes seen were of several types, but all were confined to the epithelium of the cornea, with slight changes in the stroma immediately underlying Bowman's membrane in a few. In the first case which presented, the appearance (fig. 1) was that of an irregularly curved whitish line of deposit in the corneal epithelium, concentrated maximally just below the pupil and with white dots of deposit scattered irregularly over the corneal surface. 8 other cases showed this type of change, the line in some of them having taken on a yellowish pigmentation. In a further 6 cases the widespread white dots were present with a fainter, but more regular, aggregation into curved lines in the same position, an appearance resembling the lines of force of a magnetic field (fig. 2). In the remaining 7 cases the white dots alone were visible at the first examination. Fig. 3 illustrates the appearance in the patient infested by *Clonorchis sinensis*, in whom they were clearest. This appears to be the early stage of the keratopathy because it was seen to progress to the second type of change illustrated in 2 cases examined after a period of treatment, and in 1 further case this change was seen to progress to the complete picture with yellowish pigmentation of the subpupillary line. In addition there were 3 cases in which this fully developed change regressed after the cessation of treatment, in 2 of them with the complete absorption of deposits.

Apart from this picture, which we regard as typical of the condition, there have been other associated epithelial changes in the form of irregular limbal deposits (2 cases) and small maculæ (5 cases), sometimes in association with the typical picture and in other cases appearing separately, but in all of them in cases which at some time showed the typical change. Pigmented maculæ in the epithelium were seen in 2 patients who had ceased treatment and had originally presented a linear deposit.

The gradual evolution of these changes during chloroquine treatment and the more gradual recession seen in some cases when treatment has been discontinued make it fairly certain that they arise as the result of treatment with chloroquine. The time needed for their evolution and the relationship to the dosage used are still uncertain, partly because regular observation of all of these patients, drawn from a wide area, has been impossible, but also, we are sure, because individual reactions to the drug vary so widely.

The precise nature of these changes, therefore, their permanence, and their relation to dosage and duration of treatment, as well as the range of compounds by which they may be expected to be produced, are still uncertain and further investigations are being undertaken to elicit answers to these questions, but at least 1 case which we have under observation indicates that they may lead to continued loss of visual acuity, and for this reason we have thought it wise to point out the need for careful ocular supervision during treatment with these invaluable drugs.

Reviews of Books

Rehabilitation after Illness and Accident

Editors T. M. LING, M.D., M.R.C.P., psychiatrist, Marlborough Day Hospital, London; C. J. S. O'MALLEY, C.B.E., M.B., medical director, Camden Road Rehabilitation Centre, and consultant in physical medicine, Queen Mary's Hospital, Roehampton. London: Baillière, Tindall, & Cox. 1958. Pp. 119. 12*s.* 6*d.*

"IT is probable," this book begins, "that in the history of mankind we can distinguish three stages in the attitude towards the disabled. The first . . . in which the disabled member of the tribe was left to his fate, or even liquidated. The second might be called the charitable stage. The third that of rehabilitation. Nowadays we are not satisfied with the maintenance of the disabled person, only with his rehabilitation as far as practicable to a full and normal life of work and leisure." This enlightened outlook is, however, still a new one. The best techniques for restoring the disabled are still being developed, and until Dr. Ling and the late Dr. O'Malley compiled this book no comprehensive text on rehabilitation had been written in this country.

In an easily read book, eight experts have in common a concise and forceful style—a welcome change in a subject on which many writings have been tediously hypothetical. They point straight to some of the important matters: "One out of twelve people in this country will be admitted to a mental hospital during their life-time. Nearly one half of our hospital beds are being used for the treatment of mental illness . . ."; "We have never known full functional recovery to be obtained if the patient is in danger of losing money thereby." And commenting on the need to teach doctors more about rehabilitation, "No question in this subject has ever been set in a qualifying examination for medical students." Finally, "Understanding and team work is not enough—another essential quality is the ability to handle human beings." Dr. O'Malley possessed just this quality; he died while the book was in the press, but the care and thought that he and his colleagues devoted to it make it a worthy memorial to him.

An International Nomenclature of Yaws Lesions

C. J. HACKETT, M.D., F.R.C.P., medical officer, venereal diseases and treponematosis section, World Health Organisation. Geneva: World Health Organisation. 1957. Pp. 104. 20*s.* Obtainable from H.M. Stationery Office, P.O. Box 569, London, S.E.1.

WIDESPREAD control of yaws on an international scale is impossible in the absence of a generally recognised classification of the lesions, and the nomenclature has grown up without direction and without a basis of systematic scientific observations. A great many terms are derived from picturesque folklore dating back to the slave days in the Caribbean, such as "yaws trash", "mother and daughter yaws", and "crab yaws". The difficulty of determining the order of appearance of the lesions is further complicated by latent periods and by relapsing lesions, which mean that some manifestations are wrongly attributed to particular stages of the disease. Now, thanks to Dr. Hackett, who has made a lifetime study of this many-sided disease, these defects have been remedied. He has provided a glossary defining all the acceptable terms in general use and discarding those which are misleading. A table sets out the appearance of the lesions in chronological order.

The great value of this work, however, undoubtedly lies in the 34 photographs, illustrating in a way never before achieved all the known manifold lesions. The illustrations are of a magnificently high standard, and they include 5 radiographs of periostitis and osteitis. The pictures alone make the book invaluable, and it should be in the hands of every doctor working in the tropics. A companion volume on syphilitic manifestations would be very useful.

Widows and their Families

PETER MARRIS. London: Routledge & Kegan Paul. 1958. Pp. 172. 18*s.*

THE third of the series of surveys by the Institute of Community Studies deals with the experiences of 72 widows who had lived in the East End of London, where the people are neighbourly and carry on a tradition of mutual help in trouble, and whose husbands had worked at the common trades of the area—in the docks and markets, the furniture, tailoring, and building trades, as drivers and mechanics On average, the widows had been married for sixteen years, and widowed about two when the survey was made a year or two ago, their average age was 41, and 61 of the 72 had children living The book deals first with emotional reactions to bereavement—apathy, a sense of futility and emptiness of life—and with certain associated changes 57 had difficulty in sleeping and 31 " some more or less lasting deterioration in health ", and 25 were left with feelings of hostility to society

Gone were the elaborate funerals of fifty years ago, with mutes in top hats and horses swathed in plumes, but the average cost of the funeral in this series was £57 37 of the husbands had been ill for upwards of one month before death, and 44 of the widows had been working before their husbands died 12 had remarried, and 82% of those who were still widows when the study was made were in employment 33 took a job within one month of their husband's death, the decision to start work being determined by their health, the ties of their children, the exhaustion of their savings, their loneliness, and, especially, by whether or not they had been working when their husbands died The average weekly income in widowhood was £7 1*s* 3*d*, about £3 less than that before widowhood All but 6 of the widows were receiving some kind of social-insurance benefit, mostly widowed mothers' allowance, and all but 3 of those without jobs had to claim National Assistance Few had anything in reserve

Mr Marris concludes that widowhood impoverishes social life, and that a fundamental limitation of National Insurance is its inability to protect the widow against loss of status, it could do so if it would provide benefits in addition to earnings, but it was framed in a harsher philosophy concerned only with the basic necessities of life

Understanding Your Patient

Editor SAMUEL LIEBMAN, M D, medical director, North Shore Hospital, Winnekta, Illinois Philadelphia J B Lippincott London Pitman Medical Publishing Co 1958 Pp 170 40*s*

THIS is a sketch by ten American psychiatrists of the common emotional problems and situations for which patients are brought, are sent, or come to doctors from infancy to grandparenthood The book appears partly in answer to the observation that 80% of " cases appearing for medical consultation " show " significant psychological factors in the genesis of their complaints " and partly to meet the complaint of many " professional men and leaders in American life " that many doctors fall short in recognising their patients' personalities and fail to attend to the whole man

Its multiple authorship is ironical evidence of the extreme fragmentation of medicine, of which, at bottom, these leaders complain, but the ten contributors cover their ground, and any reader who failed at the beginning to recognise his duty to his patient's personality will scarcely so fail at the end To the British reader the incursions of psychiatry into every province of medicine, hygiene, and, almost, human life may seem as striking as the intrusions of Psyche herself and perhaps a little disturbing, but it is instructive to read of the possible pattern of things to come

Chromatographic Techniques

Clinical and Biochemical Applications Editor IVOR SMITH, B SC, PH D, F R I C, lecturer in chemistry and biochemistry, Courtauld Institute, Middlesex Hospital, London London Heinemann Medical Books 1958 Pp 309 45*s*

FOR some years it has hardly been possible to open an issue of *Nature* and many another journal without reading of the application of paper chromatography or of column chromatography to the separation of yet another group of chemical compounds This book, written by a group of experts, deals with the applications of chromatography to clinical problems Nearly all of it is devoted to paper chromatography, but there are also sections on column chromatography (which uses as a supporting solid not paper but surface-active powders), particularly in its application to the separation and indentification of steroids There are valuable detailed descriptions of apparatus and techniques, many of them illustrated, and the discussion of the clinical interpretation of results is very helpful The chromatography of aminoacids and amines, indoles (including 5-hydroxyindolacetic acid), imidazoles, guanidines, purines, sugars, phenolic acids and acids of the citric-acid cycle, barbiturates, cholesterol, and steroids are all considered in detail The subject is growing very fast and no book about it could be up to date It would be easy, therefore, but not really constructive, to point out where additional information will have to be provided in the next edition

The editor and his nine collaborators have provided what is strictly a bench book, and there is little doubt that it will be a great success and find its way into almost every clinical laboratory

The Dermatologists' Handbook

ASHTON L WELSH, M S, M D, assistant professor of dermatology and syphilology, University of Cincinnati College of Medicine, Ohio Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1957 Pp 427 112*s* 6*d*

THE author's purpose was to bring together information on all the drugs about which the dermatologist should know He therefore describes not only those local and systemic agents used in the treatment of skin ailments but also a great variety of others which may give rise to drug eruptions There is in addition a great deal of irrelevant information more appropriate to a textbook of general therapeutics The material is factually accurate but it is difficult to see whom it will help, for nobody can learn from these pages how to select or administer appropriate treatment It is a useful source of information on American proprietary preparations

---

Modern Trends in Pædiatrics (*2nd Series* London Butterworth *1958 Pp 385 70s*)—The high standard of the pædiatric volume in the first series, edited by the late Sir Leonard Parsons and published in 1951, has been maintained and in some respects enhanced in the new version, under the direction of Dr A Holzel and Dr J P M Tizard The 21 contributors, 15 of whom are British, 4 American, 1 Dutch, and 1 Russian, have covered all the main growing-points in pædiatrics—notably, experimental and human genetics, disorders in the perinatal period, mineral metabolism, corticosteroids in therapy, chromatography and electrophoresis, and the use of radioactive isotopes Contributions from a physiologist, a physicist, a biochemist, a pathologist, a virologist, a neurosurgeon, and a medical statistician, among others who are not pædiatricians, emphasise how progress largely depends on the concerted efforts of specialised workers The chapter on child psychiatry does not fully represent current opinion in this important and expanding branch of child health, constitutional and somatic factors are neglected, and the discussion of treatment is limited to psychoanalysis *The editors'* policy of asking each contributor to supplement an account of notable progress with a consideration of the outstanding problems and some speculation about possible future developments has infused a spirit of research into a valuable book which is a pleasure to read

Psychotherapy, a *Modern* Theory and Practice (London Staples Press 1957 Pp 334 30*s*)—A simplified approach to psychotherapy is here presented by a psychologist, Mr E Lakin Phillips, PH D It is based on the view that all behaviour results from the " assertions " that an individual makes about himself, as he chooses now one, now another line of action, other incompatible forms of behaviour are " interfered with " The aim of psychotherapy, therefore, is to make the subject aware of what he is asserting about himself Dr Phillips claims that this does away with the need for the Freudian concept of the Unconscious as the source of inexplicable behaviour Unfortunately his ideas are developed with much prolixity of style and that detracts from the value of the book.

THE LANCET
LONDON 7 JUNE 1958

Intestinal Angina

MANY manifestations of degenerative arterial disease are already amenable to operative treatment, but until lately surgeons have taken little interest in intestinal angina. This syndrome is in many respects analogous to angina pectoris and to intermittent claudication. Like these two conditions, it is a protest reaction of ischæmic muscle strained beyond endurance, but it is the smooth muscle of the bowel wall that is in revolt. The term "intestinal angina" may not satisfy the purist, but it is less grotesque than "intestinal claudication" and more descriptive than "abdominal angina".[1-5] There is every reason to believe that the symptoms arise from ischæmia of the intestine rather than of the abdominal viscera as a whole, and they must not be confused with the common abdominal radiation of cardiac anginal pain.

MIKKELSEN[6] described intestinal angina as "characterised by post-cibal generalised cramping abdominal pain that may extend to the back. The pain occurs a short time after meals and persists for one to three hours. Minimal at first, it increases in severity as the weeks or months pass. Association of meals with this pain soon leads to reluctance on the part of the patient to eat." MIKKELSEN's statement that the attacks strike "a short time after meals" must be interpreted liberally. There is often a silent interval of two to three hours, and the composition of the meal is as important as its bulk. The crucial relationship between meals and pain is easier to miss than the rapid and almost clockwork sequence of angina of effort or of intermittent limping. The patient who nibbles at his food during the day and takes substantial meals in the evening will suffer from nocturnal attacks, and when spontaneous remission of the pain follows alkali medication, the diagnosis of peptic ulcer will at once come to mind. Hospital regime, with its small, regular, and frequent meals, may put a welcome end to the attacks, or sharp paroxysms may give way to a dull, continuous ache. Vomiting appears to be rare even with severe pain, but persistent diarrhœa and a general decline in health may suggest some inflammatory condition or a malabsorption syndrome (the latter may, in fact, coexist). Finally, when loss of weight and loss of appetite are prominent, experienced clinicians will not easily abandon their search for malignant disease. Physical examination—though it may reveal generalised or localised abdominal tenderness, and during attacks even signs of peritoneal irritation—is not diagnostic, and, apart from the frequent but non-specific finding of occult blood in the stools, laboratory and radiological investigations are likely to be negative. Evidence of degenerative arterial disease in other parts of the body is too common to clinch the diagnosis, but it will strongly support it.

It is still difficult to assess the frequency of intestinal angina as a prodromal syndrome to acute mesenteric occlusion. It is certainly possible that mild attacks are often overshadowed in the minds of both patient and doctor by the ultimate catastrophe. Carefully reviewing the past histories of 12 patients with fatal mesenteric occlusion, DUNPHY and WHITFIELD[1] found that 7 had had attacks of "abdominal angina" for weeks, months, or years before their final illness, and in 2 of the 4 cases reported by BENJAMIN[7] and by MCCLENAHAN and FISHER[8] there had been warning episodes. MIKKELSEN[6] and MANDELL[4] mention other cases. On the other hand, several recent reviews of acute mesenteric occlusion and many standard texts do not mention prodromal attacks. It is of more than academic interest to decide whether this reflects their comparative rarity or lack of awareness on the observers' part: premonitory symptoms would offer today a nucleus of hope to patients whose prognosis remains exceedingly poor. In his review of 32 cases of acute mesenteric occlusion FORTY[9] found that none of the 19 patients who had been treated conservatively survived, that of a group of 7 who had been subjected to exploratory laparotomy only 1 survived, and that 4 out of 6 succumbed after bowel resection. It is true that many of these patients had one or several of the chronic ailments of old age, but this is a risk which the surgeons will have to contend with more and more. Commenting on this gloomy state of affairs (which has remained virtually unaffected by the use of anticoagulants and of broad-spectrum antibiotics), we suggested a few years ago that mesenteric embolectomy and thrombectomy were theoretically feasible,[10] and these operations have since been successfully performed.[11 12] It cannot be claimed, however, that such emergency surgery is within the scope of routine practice; indeed, even in expert hands it might carry a mortality even more forbidding than that of bowel resection. Prophylactic operations—practised already for threatened peripheral gangrene and for ischæmic heart-disease—may prove sounder, and plans for arterial grafting in one of MIKKELSEN's cases were abandoned only because of the erroneous interpretation of the aortogram.

Atherosclerosis of the larger and medium arteries primarily involves their bifurcations. At necropsy many aortas are almost completely free from atheroma, except where they give off their main branches, and at operation for acute mesenteric occlusion the distal vascular tree, though usually bloodless and collapsed, often shows no degenerative changes. At postmortem examination of 50 patients with widespread atherosclerosis CARUCCI [13] found involvement of the first two centimetres of the superior mesenteric artery in 33, but in none had the process spread distally Mesenteric arteriography, even when the roots of the vessels are scrutinised carefully, has many limitations The vascular network of the gastrointestinal tract is rich in anastomotic pathways, but their functional value under varying conditions is unpredictable Accidentally or deliberately, the hepatic artery has often been ligated, either proximally or distally to the gastroduodenal artery [14–16], and commonly the patient survives with no ill effects Accidental division of the superior mesenteric artery is one of the most dreadful calamities of the operating-theatre, but gradual obliteration is compatible with life [17, 18] Indeed, ROB and OWEN [19] *have recorded a case in which at operation* (for resection and grafting of a syphilitic abdominal aneurysm) all three branches of the cœliac axis and the superior mesenteric artery were found to be thrombosed they could be ligated and divided with impunity On the postoperative aortogram a greatly hypertrophied inferior mesenteric artery with a large ascending left colic branch appeared to be the only source of blood-supply to the abdominal viscera Generally, intestinal angina follows complete obliteration of the cœliac axis and narrowing of the superior mesenteric artery (or the reverse) [6, 20]

Apart from its importance as a premonitory syndrome, intestinal angina can be crippling enough to demand recognition and management in its own right A change in eating habits to light, small, and frequent meals is the obvious first line of treatment, but this will not be always effective Splanchnic nerve-block has been performed in at least one case with some success [21], and ganglion-blocking and vasodilator drugs have been tried What is needed most at present is better understanding of the natural history of the syndrome, and this can come only from wider awareness of its existence, its more frequent recognition, and its close observation

New Light on Molluscum Sebaceum

MOLLUSCUM SEBACEUM (molluscum pseudocarcinomatosum, keratoacanthoma) is a common pseudotumour, usually of the face, which grows rapidly in the space of ten to twelve weeks to form a firm nodule in the skin which, clinically and histologically, resembles very closely a squamous carcinoma, but, left alone, it shrivels within a few more months, discharges a keratinous plug, and heals leaving only a scar Its distinction from squamous carcinoma, with which it was long confused, is important but not very easy, depending on close cooperation between clinician and histologist Since we last discussed this lesion,[1, 2] many descriptions of it have appeared [3–6]

It has become clear that valuable analogies can be drawn from experimental cancer research This seems to have been realised first by HAMPERL and KALKOFF [7], but detailed ad-hoc experimental studies by WHITELEY [8] and by GHADIALLY [9] have proved the point, and have shown, moreover, that an obscure corner of experimental work may be itself illuminated by the human analogy It has long been known that, notably in rabbits, a substantial proportion of skin cancers produced by painting with carcinogenic materials regress spontaneously, especially if painting ceases, but it was generally supposed that these lesions were a frustrated form of squamous carcinoma WHITELEY and GHADIALLY have now both shown *that such regressing tumours* can be distinguished from the first from the non-regressing (" true ") tumours, being closely comparable to the human molluscum The non-regressing lesions begin as squamous papillomas or keratoses, arising from the surface epidermis, the regressing lesions, they both believe, arise from the hair follicles WHITELEY has shown in addition that in the rabbit the appearance of the tumours is related to the hair cycle After the whole flank has been plucked at once, active hair growth begins simultaneously over the whole area and continues for about thirty days, after which there is a period of quiescence that normally lasts for months When the flank is painted weekly with a carcinogen the cycle is speeded up, the inactive phase lasting only two or three weeks WHITELEY found that all tumours appearing during the phase of active growth are papillomas, while the regressing lesions of molluscum type appear only during the quiescent phase

Now it has been tolerably firmly established, by study of lesions in man,[3, 10] that the growth of the molluscum is not, as appears at first sight, an explosive invasion of the underlying tissues by epithelium growing downwards from the epidermis, but a proliferation of the epithelium of hair follicles and sebaceous glands The molluscum never grows deeper—a useful point in diagnosis—than hair follicles and sebaceous glands of the area In the nose and cheek, the sites of highest incidence, the hairs are small and downy and their roots superficial, while the sebaceous glands are larger and penetrate deeper, and it is the sebaceous glands chiefly that define the depth of penetration of the molluscum Not only does the hair-follicle complex lie deeply in the skin it is also, during part of its cycle of growth, naturally and normally invasive Sebaceous glands can disappear entirely, and their re-establishment, by growth outwards and downwards from the neck of the hair follicle, involves a kind of invasive growth into the dermis The inactive hair follicle is substantially shorter than the active, and re-establishment of activity involves a brief burst of downgrowth, or invasion, by the new hair germ[11] It is thus not at all difficult to understand that, while in most tissues invasiveness spells irreversible malignancy, abnormal proliferation of the hair-follicle complex may result in a burst of growth that is invasive yet not malignant

Whiteley and **Ghadially** had already shown[12] that true tumours of the rabbit skin are commoner when painting is begun in areas of active hair growth; and this is not surprising, for in such areas the whole skin is hyperplastic and hyperactive It is equally believable that mollusca should arise at times of inactivity, for at this time the essential sensitive hair-germ lies near the surface, dormant awaiting the trigger action of the normal cyclic stimulus (unknown, but perhaps vascular[13]) to set it into sudden violent growth The carcinogen, it may be supposed, supplies the stimulus in the rabbit in an abnormal form, and so the growth produced is abnormal, but it is in the direction of normal new growth of follicles and lasts just about as long as the normal activity of the follicle In man most mollusca arise on the exposed skins of elderly people—in just the sites where, judged by the incidence of true tumours the effect of external carcinogens such as sunlight is maximal In younger men, and at other sites, there is a significantly frequent history of exposure to industrial carcinogens[14] It is thus not at all unreasonable to regard carcinogens as implicated in the lesion in man as well as in animals As **Whiteley** points out, the areas of maximal incidence are those where the inactive phase of the hair cycle is longest. Inescapably one must suppose that the molluscum is produced by the action of a mild carcinogenic stimulus on a group of resting hair follicles, exciting them to premature and perverted activity Perhaps because some minor mutation has been produced in the epithelium, perhaps because some external component of the complex machinery of the hair cycle is lacking, the growth is irregular and no differentiated products (hairs or sebum cells) result, but only non-specific keratin But the growth expands only to the anatomical limits of the normal full-grown follicle, and its growth ceases when the normal cycle would return to the resting phase. This seems, all told, a most reasonable explanation of a very remarkable lesion The idea that carcinogenic stimuli may excite intense but self-limiting bursts of proliferation in tissues normally subject to phasic activity is new, and may have other applications

An odd position, for which we must take some blame, has arisen over the nomenclature of these lesions In 1953 we suggested[1] that, since **MacCormac** and **Scarff**'s[15] original name of molluscum sebaceum was no longer tenable (being based on the hypothesis of origin from a sebaceous cyst, which was disproved) and **Rook** and **Whimster**'s[16] "keratoacanthoma" seemed unduly vague in anything except its unwarrantable assumption of neoplasia, the lesions might best be called "molluscum pseudocarcinomatosum" The name has found some favour, especially on the Continent,[6 7] but in effect this has meant that there are now three equal contenders for the title of one lesion We still dislike keratoacanthoma, but, since it has been shown so clearly that the lesion arises not (as we then supposed) from the epidermis but from the hair follicle and sebaceous glands, the objection to "molluscum sebaceum" is no longer valid This title has priority and should be accepted

A Fresh Start

No medical curriculum, however well devised, remains satisfactory for long, since undergraduate teaching should constantly take account of advances in knowledge and of society's changing needs Lately the preclinical course has been much criticised; and most plans for improvement have centred round reduction in its length and its integration with the clinical course Dr **Tanner**, in an address that appears at the beginning of this issue, recommends more radical reform Impressed by the doctor's "very wide field of operation" in "applied human biology", he calls for reconstitution of the preclinical curriculum to cover, in three years, "all the present ground of 1st M.B., 2nd M.B., and general pathology, but reorientated in consecutive courses entitled Cellular Biology. Organisation of Mammals, and Organisation of Man". These should prove understandable and attractive to the student who thinks of "medical practice as an endeavour to understand individual people in relation to their hereditary endowment, their upbringing, their family, their social position, and their whole culture, and as an endeavour to guide them, so far as may be, from childhood to old age through the squalls and doldrums so that they slip as seldom as possible over that invisible equator which divides health and disease, whether of mind or body" Certainly any student who receives such a preclinical education will not thereafter happily tolerate a clinical training consisting of "instruction by a multitude of specialists each on how to be an elementary specialist in his own particular field" (Even students who have had a more orthodox preclinical course can find their clinical years difficult and unsatisfactory "Training by a process of apprenticeship", writes a student, "works only when the master practises the trade that his students intend to follow"[17])

It should be possible, as **Tanner** says, now that the General Medical Council has given freedom and encouragement to experiment in medical schools, to put such a plan into action There would no doubt be some difficulty in introducing a preclinical course lasting three years, of which the first replaced the last year of study at school But the largest obstacle to fulfilling this plan—or any other well-constructed scheme of adaptation to current needs—is likelier to be that of finding a medical school with the courage, initiative, and determination to try it It seems probable that zeal less than **Tanner**'s, combined with the powers of reaction, will cause this scheme, like many another, to get no further than the curriculum committee, which doubtless will lay it aside after comfortably agreeing that it is nebulous and is not a "concrete plan", for only "concrete plans"—by which, we suspect, is meant detailed timetables—are heavy enough to replace the weight of tradition And timetables can be made only by a group of department heads and never by the single advocate of a new approach Hence it seems certain that no established school will undertake an experiment as radical as that advocated by TANNER But, if all the older schools are tied to their dead past, the same cannot be said of new schools, such as that of the University of Western Australia To break the mould of the existing curriculum it may be necessary to start in Britain a new medical school Its staff, drawn from many different traditions, might soon be fused into an enthusiastic team by competition with its orthodox rivals

Annotations

DIAGNOSTIC CENTRE FOR SOUTH LONDON

IN the years just after the war, the Pioneer Health Centre, established at Peckham by the late Dr Scott Williamson and Dr Innes Pearse, was one of the medical institutions in which our visitors from abroad showed most interest But by 1950 financial difficulties prevented its continuation on the original lines A decision was reached to dispose of the property to an authority prepared to use it for purposes related as closely as possible to the aims and objects of the founders, and in 1951 it was bought by the London County Council, under which it has continued as the Queens Road Health Centre The two departments of the Council with interests akin to those of the founders were those of public health and education The education department took over facilities including the swimming-pool and the gymnasium, and established a thriving institute for adult education which offered a wide range of classes—in dressmaking, millinery, pottery, and even boat-building The health department used the centre for a day nursery, for certain other maternity and child-welfare activities, and later for a child-guidance clinic For various reasons, it did not prove possible to start group practices for medical and dental practitioners, and the setting-up of a research unit consequently remained in abeyance, though the Minister of Health had expressed the hope that research would be undertaken, in which case he would consider assisting it The Sir Halley Stewart Trust, having been generous subscribers to the Pioneer Health Centre, retained their interest in the new Queens Road centre

In 1956 it became possible to make further progress General practitioners practising within a mile of the centre were invited to a meeting, with representatives of the Sir Halley Stewart Trust, the College of General Practitioners, the London Local Medical Committee, the South East Metropolitan Regional Hospital Board, and the local health authority, and afterwards 15 of them expressed their interest in the development of the centre At a subsequent meeting attended by 25 practitioners a subcommittee was formed to discuss details It was generally agreed that a close link with the College of General Practitioners was essential, and the Sir Halley Stewart Trust agreed to pay the expense of a medical director to organise and direct research at the centre over a period of five years, at a cost to them of over £12,500

Provisional plans have now been drawn up for adaptation of the building so that it will provide a diagnostic medical centre for the use of local doctors The cost of the internal adaptation will amount to about £16,000, of which the Nuffield Foundation is prepared to give £12,000 The grants from the Sir Halley Stewart Trust and the Nuffield Foundation are subject to the running costs being borne by the London County Council As a beginning, the intention is to offer, to all general practitioners in the neighbourhood, X-ray and pathological laboratory diagnostic facilities, and physiotherapy It is hoped that these doctors will be able to meet each other, more frequently, in the common-room of the centre, that they will have a closer link with consultants, who will discuss cases with them there, and that some of them will participate directly both in research projects affecting general practice and also in the training of medical students

PHYSICAL CHANGES IN THE PROLAPSED DISC

THE intervertebral disc in man comprises three distinct elements—the nucleus pulposus, the annulus fibrosus, and the cartilage end-plates of the vertebræ Eckert and Decker [1] stated that each of these elements degenerates with age The cartilage plate becomes thinner and its cellularity diminishes, and it may become torn In the annulus fibrosus swelling of the fibrous lamellæ and hyalinisation of the fibres may be seen, while the nucleus pulposus exhibits central fissuring, cavitation, and sometimes fibrosis and calcification These changes in the nucleus are associated with relative dehydration The normal nucleus consists of a three-dimensional lattice of collagen fibrils [2] in which lies a mucoprotein gel which is responsible for the hydrophilia of the nucleus With the increase in collagen and diminution of mucoprotein as a result of increasing age, hydrophilia is diminished

The mechanical behaviour of the nucleus pulposus when the spine is removed at necropsy has been analysed by Petter [3] and by Charnley [4] Its affinity for water may be a major factor in the production of back pain, indeed, its power to swell in the presence of water has been compared to that of laminaria Hirsch [5] noted that injection of saline solution into the intervertebral disc may produce severe pain in the back Changes in the fluid content of a disc may account for the attacks of lumbago which sometimes precede true prolapse of the disc

It is now generally conceded that trauma is not a large factor in the production of disc prolapse, and may often be absent The evidence for this has been summarised by Charnley, who contrasts the clinical picture of the disc lesion with that of spinal injuries Perhaps the common failure of the pain to subside with rest is the most cogent clinical evidence against the lesion being traumatic—apart, of course, from the absence in many cases of a history of injury or even of strain

Prolapsed discs removed at operation have recently been examined by Hendry,[6] who has determined their capacity to take up water, comparing this with that of the normal nucleus By comparing the weight of the removed nucleus after complete hydration in physiological saline solution with that after desiccation, it was possible to estimate the hydration of the prolapsed disc It is apparent that the deranged disc has a greater affinity for water than its normal fellow, but when the hydration is related to the dry weight of the disc it seems that the abnormal nucleus pulposus is in fact relatively hydrophobic in the body—that is, it is less hydrated when it is prolapsed than is the normal disc in situ.

If changes in the disc precede prolapse these changes may consist, not, as is commonly supposed, in swelling of the nucleus but in relative dehydration, and the prolapse of the disc presumably results from undue compression strain on the annulus fibrosus. Relative desiccation of a degenerated disc would fit in with our knowledge of its structure, and with the changes which occur with age. On the other hand the gross degeneration in older people is rarely associated with prolapse. If desiccation in discs is a major factor in their prolapse, it is difficult to understand why the elderly remain relatively free from major disc derangements. In the patient with backache without sciatic pain, changes in the disc can still be a major cause of symptoms, and it seems more reasonable to assume that the sudden episodes of back pain are due to an increase rather than a decrease in tension within the disc. It is quite clear that further studies of the physical properties of the intervertebral disc are essential.

EMERGENCY RESUSCITATION

IN the emergency resuscitation of someone who, for whatever reason, has ceased to breathe, the most important and urgent necessity is to introduce oxygen into the lungs, preferably in a volume sufficient to allow carbon dioxide to be removed. For this it is important that the airway is kept clear, which entails not only removal of any foreign material that may be there when the patient is first seen, but also the prevention of further foreign material, particularly vomitus, from entering subsequently. In practice this almost inevitably means treating the patient in the prone, not the supine, position. A subsidiary but important point is that the minimum strain should be thrown on the circulation, whose integrity is impaired in many of the conditions in which emergency resuscitation is needed.

If mechanical apparatus is to be used successfully for this purpose it must be easy to use and reliable, and the manufacturers must make it quite plain what serviceing is needed and at what intervals. It is unrealistic to expect people unused to this type of apparatus to service it efficiently without special instructions, and the manufacturer must emphasise this if he wishes his apparatus to be used with success. The lay press has recently extolled a resuscitation machine for use by trained lay people, notably ambulance men. This machine is intended to assist patients who are apnœic by providing artificial respiration by intermittent positive pressure. Two questions arise in connection with such a device. First, in what circumstances is it likely to be needed? Second, is it technically satisfactory?

In many large industrial concerns a workman may need artificial respiration, either because of poisoning by carbon monoxide or an industrial solvent such as trichloroethylene, or because of electric shock. The situation is ideal for rapid and efficient treatment, for the victim is likely to be discovered quickly, and large industrial concerns run their own well-trained emergency service, often headed by a doctor, which can be on the spot within a very few minutes. In such circumstances a resuscitation machine may prove a useful item. In domestic practice, however, the situation may be very different. Victims of coal-gas or barbiturate poisoning are often not discovered for a long time, and the point of primary importance is to get an ambulance to the victim at the earliest possible moment after the alarm is given. This is much easier now that many ambulances are in radio communication with their headquarters. It is not practicable to carry a resuscitation machine on every ambulance, and it would be a retrograde step if any delay was introduced by instructions that such a machine must be fetched. The Holger-Nielsen method of manual artificial respiration is easy to learn[1] and effectively ventilates the lungs.[2] It is questionable whether it is not better to use this method of artificial respiration (or one of its modifications) and transfer the patient to hospital than to rely instead on apparatus which may not be immediately available, which may be imperfectly familiar to the operator, and which may from disuse be out of order.

The apparatus described runs off an oxygen cylinder, which is also used to operate a sucker. It is excellent that a sucker is provided and that the accompanying instructions emphasise the importance of a clear airway, but the value of this is lost because the patient is normally treated supine. Even a skilled anæsthetist cannot protect a patient from the danger of inhaled vomitus in this position. At the end of expiration subatmospheric pressure is applied to the trachea—a feature which is rightly claimed to assist the venous return to the heart.[3 4] The benefit of this, however, is entirely dissipated because expiration is slow—far slower than would be acceptable in any machine for long-term positive-pressure respiration—so that the mean mask pressure, a principal factor in determining the effect on the circulation,[3 4] is unduly high. Emergency resuscitation by intermitted pressure respiration should be further tested. But if apparatus is to be used it should be reliable, and hence simple.

FERTILITY

PAPERS read at the annual conference of the Society for the Study of Fertility, held in London on May 29–31, testify to the intricate constitution of human fertility. Small wonder that infertility is attributable to a host of different causes, and that inquiry into the attendant problems involves widely differing disciplines. Clinical investigation plays an essential part, not only in the development of palliative and sometimes of remedial measures, but also in permitting, under favourable circumstances, definition of specific problems for the guidance of basic research.

Clinical study is perhaps most rewarding when morphological abnormality is found to be the essential cause. The patulous cervix, for example, can be implicated in many cases of spontaneous abortion, and the simple operation designed to reinforce the cervical musculature, was described by Mr V B Green-Armytage, it is reported to maintain pregnancy in most cases. On the other hand, recourse to some operative measures may not be justified even though a priori they seem rational. Mr H H Fouracre Barns described a careful analysis of numerous cases of uterine retrodisplacement which showed that the condition should not be held responsible for infertility. Pathological states less obviously connected with the reproductive process may be potent sources of failure. This was well brought out by Mr Linton Snaith and Dr G R Peberdy (Newcastle upon Tyne), who maintained that emotional stress may induce demonstrable abnormalities of function in the female genital tract.

Dr Bernard Sandler (Manchester) adduced strong evidence that comparatively minor infections of the nasopharynx can be causally connected with infertility, eradication of the invading organisms, which may or may not simultaneously infect the cervix uteri, was in most instances shortly followed by normal pregnancy By contrast, even though endocrine function is fundamental to reproductive function, endocrine therapy in cases evidently involving hormonal imbalance is notoriously disappointing Dr Margaret Jackson (Crediton, Devon) reported that administration of some of the new oral progestogens was consistently of small value for the maintenance of pregnancy, though they were often effective in the treatment of leucorrhœa and amenorrhœa

In the research field, Miss H M Bruce reported a more encouraging finding—namely, that a course of treatment with the progestogen 19-norethisterone induced ovulation in mice, apparently by a kind of release mechanism, immediately after treatment was stopped Observations indicated that, during treatment, ovulation and vaginal œstrus were suppressed, psychic œstrus was displayed at intervals, but coitus was *not followed* by pregnancy Possible causes of infertility in man were suggested by other papers based on research projects Arguing on analogy between mouse and man, Dr A J Bateman (Manchester) pointed out that embryonic death in the first week, or associated with miscarriage at 28 days and $2^1/_2$ months after conception, may reasonably be ascribed to the development of dominant lethal mutations—a hypothesis that is especially important in view of the increasing radioactivity in the world today and its acknowledged mutagenic effect

These and other communications at the conference support the idea of fertility as a state directly maintained by many and varied endogenous and exogenous influences, and dependent on the functional and structural integrity of the germ-cells, which in their turn are at the mercy of many different agents It is perhaps one of the most diversified of biological phenomena, offering rich opportunity for intellectual adventure and experimental investigation

THE WAALER-ROSE FACTOR IN RHEUMATOID ARTHRITIS

THE discovery by Waaler in 1940[1] and independently by Rose et al in 1948[2] that the serum of patients with rheumatoid arthritis could potentiate the agglutination of sheep cells sensitised with rabbit amboceptor imparted a tremendous impetus to serological research into the "collagen" diseases As a result of the work of the past ten years it is now definitely established that the factor responsible is found almost exclusively in rheumatoid arthritis

Many attempts have been made to isolate the factor in a pure state, and it is generally agreed that, although some of the earlier studies suggested that it belonged to the β-globulins, electrophoretically it behaves as a -globulin Apparently the earlier confusion was due to a tendency for the factor to migrate with the β-globulins when these are present in their absence the factor undoubtedly moves with the γ-fraction A simple method of effecting moderate purification was introduced by Svartz and Schlossman in 1953[3] They found that dilution of the serum with distilled water followed by cooling to 4°C led to a precipitate in which most of the activity was retained When redissolved and electrophoresed on a starch column this cold-precipitated material moved as a single band with a speed corresponding to a fast -globulin Since the active factor could not be further purified by this technique, Svartz and her colleagues[4] turned to ultracentrifugation A top and a bottom fraction were thus obtained with an obvious concentration of the active factor in the bottom fraction, but repeated centrifugation led to loss of activity Final purification was achieved by ion-exchange chromatography on carboxy methyl cellulose—a method by which Lospalluto and Ziff[5] had already achieved a 500 fold concentration The product obtained by Svartz *et al* when they subjected the cold-precipitated fraction to this type of chromatography is apparently a single substance judged by chromatography, electrophoresis, and ultracentrifugation Its sedimentation constant is 18 7S

These results of Svartz et al do not agree completely with those of Franklin et al[6] at the Rockefeller Institute, New York They find that on ultracentrifugation of whole serum the rheumatoid factor is almost entirely concentrated in a fraction whose sedimentation constant is 22S This heavy fraction is readily dissociated by 6*M* urea into two fractions of 19S and 7S, the 19S fraction retaining the biological activity of the rheumatoid factor It seems probable, therefore, that differences of technique between the two groups of workers favour association in one case and dissociation in the other From the closer correlation between biological activity and concentration claimed by Svartz et al it seems that their fraction with sedimentation constant of 18 7S must be regarded as the purer

When the differential agglutination test was first described most investigators believed that the serum factor promoted agglutination reactions in much the same way as albumin and other macromolecular substances promote agglutination But more recent work has shown that the rheumatoid factor reacts in a more specific fashion with γ-globulins from a wide range of species The reaction does not involve normal γ-globulin in its native state but γ-globulins that have undergone denaturation as a result of ageing, heat, or specific interaction with antigen Glynn, Holborow, and Johnson have therefore suggested that the Waaler-Rose factor is probably an antibody to γ-globulin, not in its native state but to reactive groups exposed as a result of denaturation and shared by the globulins of many different species The mechanism is similar to that described by Coombs and Coombs[8] as producing immunoconglutinin—i e, the exposure of antigenic groups on complement as a result of an unfolding of the molecule when it is absorbed on an antigen-antibody complex The ultracentrifugal demonstration of the existence of the rheumatoid factor as a readily dissociable complex with other components of the γ-globulin complex may be a manifestation of its antibody nature with a specificity for reactive groups in other γ-globulins We agree with Franklin et al[6] that "the possibility that the 22*S* component might represent a soluble antigen-antibody complex appears worthy of investigation"

SOME PROBLEMS OF PSYCHIATRY IN PATIENTS FROM ALIEN CULTURES*

G. M. CARSTAIRS
M.A., M.B. Edin., M.R.C.P.E., D.P.M.
MEMBER OF THE MEDICAL RESEARCH COUNCIL SOCIAL PSYCHIATRY RESEARCH UNIT, INSTITUTE OF PSYCHIATRY, MAUDSLEY HOSPITAL, LONDON, S.E.5

A RECURRENT theme in anthropological studies of primitive societies has been the myth of psychosis-free cultures.

Ellsworth Faris (1937) thought schizophrenia non-existent among the forest Bantu, and Seligman (1929) thought it unknown in New Guinea, Lopez (1932) thought none was to be found in the Brazilian interior. Laubscher (1937), however, found no lack of mental illness among the Cape Bantu, and considered schizophrenia their commonest form of psychosis. In 1945 Maloney revived the myth in favour of the Okinawans, but in 1952 Wedge showed that rates for psychotic breakdown were higher in Okinawans than in any of the other immigrant groups in Hawaii. In Formosa, Lin (1953) found prevalence-rates of the major psychoses which are not unlike those shown by European populations.

Mention should also be made of exaggerations in the opposite direction. One American anthropologist, of great distinction as an anthropologist but perhaps less well versed in abnormal psychology, studied the inhabitants of the Melanesian island of Alor for a year and a half and came to the conclusion (which was only strengthened by an analysis of their Rorschach responses) that they were all fundamentally schizophrenic (Du Bois 1944). Yet somehow they survived, and fended for themselves, and married and reared families.

Although in fact there seems to be no social group which is *immune* from psychotic breakdown, the relative incidence of the major forms of psychosis may be quite different in different societies.

Kraepelin, in 1909, was struck in Java by the paucity of cases of well-marked depression "such as fill the observation wards at home", Carothers (1953) and Laubscher (1937) have both remarked on the rarity of psychotic depression among Africans—in Kenya and in South Africa respectively. In a "true prevalence" study, not dependent (as were the other observations) on hospital admission figures, Lin (1953) showed that the ratio of schizophrenic to manic-depressive cases, which is about 3/1 in European surveys of this kind falls to 2.5/1 in his Formosan population. (On the other hand, alcoholism and psychopathy were almost unknown in Formosa.)

My own experience in India was on similar lines. When I lived for a year (and practised medicine) in a village of 2400 inhabitants, I was aware of only one case of severe depression—and that did not last long. In his practice in Leicestershire Watts (1956) would expect to see 12 cases of psychotic depression in a group of this size during the course of a year.

Not all the evidence points in this direction, however. A study of the Hutterite community in North America (a farming community, of the Anabaptist sect, who practise a primitive Christian morality, holding all worldly goods in common, and who are remarkable for their strong sentiment of brotherhood and solidarity) showed that this community was *not* immune from mental illness, as some visitors had reported but among them depressive psychosis was much more frequent than schizophrenia (Eaton and Weil 1955).

Another legend which dies hard is the assertion that there are forms of insanity peculiar to the members of particular cultures. There is *some* truth behind this assertion, for conditions such as *witigo* among the Ojibwa and Cree tribes in Arctic North America, the celebrated running *amok* of the Malay, or the *utukwasa* of the Cape Bantu have a content which is imposed by their particular cultural tradition. Yet the form of the illness is found to correspond to a familiar, indeed a universal, pattern. Knowledge of the relevant cultural stresses may be important in the anticipation of acute illnesses of this kind, and in the aftercare of any patients who may recover from the acute psychotic breakdown, but it is less essential for the diagnosis of the established condition. (An exception to this generalisation is that in West Africans organic psychosis, especially that due to trypanosomiasis, can easily be mistaken for schizophrenia (Tooth 1950).) The gait, the posture, the expressive movements of a catatonic, a manic, or a melancholic patient have a remarkable similarity, whether he be a Japanese, an Indian, a Dutchman, or a Scot.

There is, however, no such reassuring familiarity when one approaches the diagnosis of psychoneurotic or psychopathic states.

Culture and Neurosis

Unfortunately, tolerance and respect for the values and customs of alien cultures do not seem to be natural attributes of mankind. They have to be learnt, and many people have strongly resisted this type of learning. Formerly, the observation and analysis of alien cultures was of interest primarily to anthropologists, but in recent years psychologists also have found that the study of man in society is an essential part of their discipline. It has come to be generally accepted that social learning enters largely into the formation of normal and abnormal personality.

Indeed, studies of personality in culture (see Hallowell 1952, Mead 1952) have altered the whole concept of psychological normality. Not merely have they greatly extended our appreciation of the possible range of normal human behaviour, but rather a new dimension has been recognised—the cultural dimension.

This is most apparent (Benedict 1934) in compact homogeneous societies, which offer a very restricted choice of forms of approved behaviour to their adult members. Each of these societies has a very clear picture of what it considers normal or well adjusted, and the range of socially approved personalities in various cultures is wide indeed.

For example, the Comanche were one of those very warlike American Indian tribes whose boys were schooled from infancy in stoicism, courage, ferocity in combat, and boastful self-assertion. The Comanche shared with other tribes, such as the Navaho, a vigorous belief in the immanence of spirit forces. In these Plains tribes it was a necessary and expected event in the life of every young man that he should have certain hallucinatory experiences, in which the spirits would appear before him and give him significant advice. In these communities a man might be seriously handicapped in life because, in spite of undergoing strenuous ordeals, he did not succeed in experiencing this vision.

In complete contrast are the Zuñi Indians. Their culture sets such store upon passivity, conformity, and individual self-effacement that a person who is so "abnormal" as to display undisguised personal initiative, ambition, and drive runs a grave risk of being branded as a wizard and hung up by his thumbs (Mead 1939).

It seems, in fact, that each society lays particular emphasis on one or other of the many possible patterns of human behaviour. Those individuals who show this type of personality in high degree will be its leaders and its saints, those who develop the dominant traits to a slighter extent will be its rank and file, and those who, for innate constitutional reasons or because of some peculiarity in their upbringing, express a bias towards an alternative pattern of behaviour may find themselves regarded as delinquent or insane To the average man the demands of his society seem right and natural, but to the deviant they may seem nonsensical, unreal, and wrong

---

* Based on a paper read before the Section of Psychiatry of the Royal Society of Medicine on Feb. 11, 1958.

It is worth remembering, too, that similar differences may be apparent in the same society at different times Persons who were regarded as saintly in medieval England might well be diagnosed as schizophrenics today, and, on the recommendations of the recent Royal Commission, some famous Elizabethans might be detained as psychopaths

If, then, cultural influences so largely determine the concept of normal human behaviour, it is essential that the parameters of the normal should be clearly known before we diagnose a person as abnormal But in fact they are not always known A British psychiatrist practising in East Africa wrote ten years ago "We in Africa have not got a Normal for our basis, because we have never taken the trouble to study African Normality We have so far judged our cases on their departure from a European Normal, if we have judged them at all" (Mackay 1948) Since then Carothers (1953) has made a spirited attempt to make good the deficiency, but African critics of his monograph on the African mind have not hesitated to point out that he still tends to depict it as an imperfect version of European mentality rather than as a separate personality pattern—or group of patterns, because African culture is much too diverse to be included in one descriptive category

Europeans have been slow to make the effort to learn the dimensions of normal behaviour in alien societies, but this is no longer the concern only of Europeans In increasing numbers our African, Indian, and other Eastern colleagues are also specialising in psychiatry, and already they have begun to show an awareness of the cultural dimension in psychiatric diagnosis, and an awareness, also, of the fact that a medical curriculum modelled strictly on Western lines may not adequately prepare them for practice in their own countries

Advantages of Sorcery

When practising medicine in villages of northern India I became familiar with some of the pitfalls which beset the diagnosis and treatment of neurotic disorders in an unfamiliar culture Needless to say, misunderstandings commonly arose between my patients and myself At first I was rather surprised that so many of my village patients offered me their wrist, without my asking, as if expecting me to feel their pulse It was only after several months had passed that a man highly regarded in that district for his possession of magical charms, explained to me that my patients were not concerned about their pulse, they believed that I, like other local healers, could tell by the quivering of the tendons in their wrist what kind of witch, demon, or sorcerer was responsible for their illness

It was from the village *topi-wala*, or cap-maker, that I learned an essential part of medical practice in this community when you treat a patient, no matter how grave the prognosis or how uncertain your remedy, the treatment must always be accompanied by the formula "Do this, and take this, and you will *certainly* recover" To fail to give this assurance was regarded as malpractice—it was tantamount to saying "I don't care if you get better or not" In a community where magic, sorcery, and potent incantations were firmly believed in, such an attitude could readily be interpreted as a hostile attack

In this countryside major infections are common dysentery, typhoid, smallpox, pneumonia, and tuberculosis all took their toll, and each serious illness tended to be aggravated by fear of the malevolent supernatural agency threatening the patient's life I came to recognise that the local healers whom the villagers were accustomed to consult did them a real service in allaying this acute anxiety, even though they might do little to influence the course of the infection This was brought home to me by a rather humbling experience

One night a bullock-cart drew up on the roadside near the village where I was living, and I was asked to see a patient He was a thin middle-aged shopkeeper from a village some fifteen miles off and appeared to be very ill So far as I could judge, he had recently had typhoid fever, and during his convalescence he had developed severe heart-failure He was breathless and very frightened, his liver was enlarged, and his pulse-rate was over 130

I gave him a heroic dose of digitalis, and next day, finding him no better, repeated the dose Next morning I found him a changed man, quieter, less dyspnœic, and with a steadier pulse, but I could not take the credit for his recovery He explained to me now that he had indeed been on the brink of death because an enemy had put a deadly charm on him, but just in time he had found a healer with a still more potent counter-charm This healer had branded the back of his neck with a red-hot iron and exorcised the evil influence

I saw this patient in his home once or twice more during the next few weeks He developed cardiac œdema and died, but he died tranquilly

This case was a reminder that acute anxiety cannot be relieved by reassurance unless, first, it has been fully abreacted and this patient had been unable to tell me about his *real* fear, when he most needed help, because, being a white sahib, I quite obviously could not understand about such things

At the time I was a little hurt, even a little angry with this patient for his perversity in rejecting the "realistic" help which I offered him and for being so obviously benefited by the magical help which he received from my rival practitioner, but the experience was repeated so often that I soon became accustomed to it

Dissociation and Surrender

Probably the most frequent expression of what *we* should call a psychiatric disorder, among those Rajasthani villagers, is the phenomenon of hysterical dissociation The capacity to pass into a trance-like state in which normal consciousness is suspended while an alien spirit takes over and speaks through one's lips is highly developed in this community, everyone sees it happen to others and expects without question that in similar circumstances it will happen to oneself—and it does This institutionalisation of trance-like states is, of course, something which is found in many parts of the world, and not only in primitive societies On my return from India I read for the first time the paper by Sargant (1949) describing the states of dissociation which he saw being induced during highly emotional revivalist meetings of the snake-handling religious sects in the southern States of America, and I was reminded at once of the rhythmical hymn-singing and the mounting fervour which led to a similar climax in our *satsangs* in north India Both of these, it might be pointed out, are socially approved extensions of the limits of normal experience rather than signs of abnormality, but in India, I found, states of dissociation occurred in many other contexts as well.

I have already mentioned that most physical illnesses were aggravated by a fear of supernatural powers at work. Often, either spontaneously or with prompting from a man who knew healing charms, the patient would surrender his consciousness to the responsible witch or evil spirit. Two things impressed me in thinking over the many incidents of this kind which I had seen. First, how readily it came about. In our more educated and more sophisticated communities we deplore such excessive surrender of self-control, but perhaps we lean too far in the other direction: certainly Shorvon and Sargant (1947) have shown that, at times, a total surrender of our customary restraint and self-consciousness in a violent emotional abreaction can relieve us of a burden of pent-up anxieties. Secondly, I was impressed by the explicit way in which the terrifying fantasies accompanying sickness found expression in these trance states, and so could be dealt with—but not by me, so long as I remained a sahib, someone from the outside world who did not understand about the witches, ghosts, and demons whose presence was felt to be so close and so threatening.

Barriers to Communication

One does not, of course, have to go so far afield to find instances of this type of barrier to communication: it occurs commonly in the general practitioner's surgery, and one of its commonest forms, as Donaldson (1958) reminds us, consists in the patient's reluctance to reveal the cause of his anxiety—about cancer, for example—for fear of being laughed at. Another general practitioner, who has demonstrated his ability to deal with minor mental disorders in his surgery, has emphasised that the most important thing is to be able to sense when a patient is trying to tell you what is really the matter, and to help him to put it into words (Model 1957).

To do this successfully, two attributes are necessary in the doctor—a thorough familiarity with the patient's personal background (such as the general practitioner commands par excellence) and the ability to convey to the patient that whatever he says will be listened to sympathetically and without ridicule.

In the case of African and Oriental patients who consult us in this country, particularly in students from overseas, we seldom know as much as we should like to do about the cultural background to their personal problems, and so it becomes doubly important that we should succeed in winning their confidence. In these interviews we do well to remember that many of these young people are, perhaps for the first time in their lives, being compelled to fend for themselves without the support of their kinsfolk—and this in an environment which is profoundly unfamiliar in all the unconsidered details of daily living. In these circumstances, a certain hypersensitiveness or even a paranoid outlook must be considered a natural rather than an abnormal reaction.

Sometimes, once confidence has been established, the presenting problems of these overseas students can be dealt with on a fairly superficial level. But often it is not so simple, especially when the most important factors in the mental conflict are not readily accessible in the patient's consciousness.

The example which comes to my mind is the syndrome known to my patients as *jiryan*, or "loss of semen." I have described elsewhere (Carstairs 1956) the clinical features of this syndrome. In brief, it consists of a chronic anxiety state in males, in which the patients complain of exhaustion, inertia, and wasting away of the bodily tissues, although they appear normally robust on inspection and are capable of vigorous exertion in emergencies. It is, in fact, akin to effort syndrome, but instead of ascribing their weakness to heart-disease these patients are convinced that it is due to the leaking away of their semen, in which (they believe) reside the health and strength of the body. Nor is this merely a conscious rational fear—as cancerphobia often is. It is very deepseated and persists in spite of the assurances of quacks and medicine-men of all kinds.

I believe that *jiryan* is the commonest form of anxiety neurosis among men of the few Indian communities which I know well, and I ascribe it to certain characteristics of their upbringing, particularly the relationship with the father, which is so patterned as to emphasise œdipal tensions yet also to make it difficult ever wholly to resolve the œdipal complex. The upbringing of a high-caste Hindu boy in these communities requires that he accept a multitude of restrictions in which the two dominating themes are deference to his father and to all father-figures, and severe restraint in his emotional life—especially in the presence of his elders. A married son continues, as a rule, to remain in his father's household, but etiquette demands that he should deny himself any expression of independence, and even act as though he did not experience a sex life of his own. In these joint families, a son must ignore his wife if his father or his mother is in the room, if he wants to say something to her, he has to address his remarks through his elders.

It is against this background that we have to evaluate the constantly recurring complaint of loss of semen, with its attendant feelings of weakness and impotence. Here neither magical reassurance nor the quack remedies which are to be found advertised in profusion in the Indian press can give lasting benefit. The patient needs to be helped to recognise his real fear, which is the fear of offending his all-powerful father, before he can begin to master this recurrent anxiety which haunts his progress towards emotional maturity.

In this, as in the other instances which I have cited, the emotional ingredients of the syndrome are familiar enough, but they find expression in particular patterns of behaviour which at first we may have difficulty in recognising and in interpreting correctly. There is, I am sure, no short cut to the very full and sensitive appreciation of the nuances of a culture which is necessary if one is going to attempt deep psychotherapy. Many distinguished psychoanalysts have shown themselves capable of insight into one or more cultures besides that in which they were reared, but the more profound the psychological exploration the further it must go into the recesses of the patient's cultural origins. Writing from Buenos Aires, Krapf (1955) pointed out that, when he analysed multilingual patients, there always came a time when they involuntarily abandoned the language of their adult life in order to give expression to elemental emotions and infantile attitudes in their mother tongue.

Most of us, in treating patients from alien cultures, will always be denied this degree of understanding, but we can go quite a long way simply by remaining aware of the existence of their very different early emotional experiences, and of the different patterns of fantasy to which these experiences have given rise.

Our Own Society

This is true also, in some degree, of our dealings with patients who come from different subcultures in our own society. Both diagnosis and psychotherapy can be quite severely handicapped by the barriers to communication between a middle-class psychiatrist and a working-class patient This has been demonstrated most clearly by Hollingshead and Redlich (1958), who showed that the treatment accorded to patients attending the same psychiatric clinic was related more closely to the patient's social class than to his mental condition They have documented this statistical finding with telling excerpts from interviews between psychiatrist and patient, which show that neither properly understood the other's language or his different sense of values

That this gulf of incomprehension still exists can partly be laid at the door of psychoanalysis Because Freud's discoveries were made in the course of treating patients from a quite restricted social class, he and some of his followers have tended to over-generalise their theories to include all sorts and conditions of men It may indeed be true that the mental mechanisms are the same in patients from different social groups, but the experiences on which they work may well be significantly different, as Malinowski (1927) pointed out

Freud himself was not unaware of this In a letter to his fiancée written in 1883—long before his first publication in psychopathology—he reflected upon the obvious *differences in life-experience, in behaviour, and in value* between the Austrian intelligentsia and the working classes "I *will* not follow these thoughts further, but one might show how 'das Volk' judges, believes, hopes and works quite otherwise than we do There is a psychology of the common man which is somewhat different from ours" To our loss, he never did return to develop these thoughts further

We need a fuller understanding of the social environment from which our working-class patients come, not merely because it may prove to have some importance in the ætiology of their mental illness—although this has yet to be conclusively established—but more immediately, so that we can make a just evaluation of their symptoms and behaviour

Recently, when reading a paper to the British Sociological Association, I was taken to task for accepting instances of physical assault as an indication of mental disturbance in chronic psychotics living in the community I was asked whether I knew how often wife-beating occurred in the ordinary course of events in the streets in which these patients lived—and I had to admit that I did not know

We must look to the sociologists to make good this gap in our knowledge about our own society, and they are doing so—for example, in the admirable studies emanating from Bethnal Green (Young and Willmott 1957, Townsend 1957) But, until we know enough about their social background to meet them halfway our clinical task in dealing with working-class patients is not unlike that with patients from other, still more unfamiliar, cultures—to take extra pains to overcome the patient's awkwardness in unburdening himself, and to suspend judgment, in our appraisal of his complaints, until we have succeeded, in part at least, in seeing the situation from his point of view

GENERAL MEDICAL COUNCIL

In his address at the opening of the Council's 196th session on June 3, Sir David Campbell, the president, said that in recent months steps had been taken towards reciprocal arrangements for registration with two further territories of the Commonwealth On Oct 31, 1957, an Order in Council was made applying part III of the Medical Act, 1956, to Uganda This Order enabled the Council to grant registration to persons holding the licentiateship in medicine and surgery granted by Makerere College On May 7 another Order in Council had been made with reference to Western Australia, where a medical faculty had recently been established in the university It was proposed that the University of Western Australia should begin to grant medical degrees in the latter part of next year, and the question of a visitation of the university on behalf of the Council with a view to recognition of the degrees was being studied At their meeting the next day the Disciplinary Committee would have before them the draft of a new notice to be issued for the guidance of medical practitioners in place of the present "Warning Notice" Since 1914 no alterations of substance had been made in this notice, apart from the inclusion of the new sections in 1916 and 1923 The present notice included no reference to some of the most common or grave offences of members of the medical profession at the present time The committee might feel also that the time had come to discard the somewhat minatory title of "Warning Notice" The part of the new notice dealing with infamous conduct would include a definition by Lord Justice Lopes in 1894 "If a medical man in the pursuit of his profession has done something with regard to it which will be reasonably regarded as disgraceful or dishonourable by his professional brethren of good repute and competency, then it is open to the General Medical Council, if that be shown, to say that he has been guilty of infamous conduct in a professional respect"

"Members of the Council," Sir David concluded, "are not unmindful of the temptations and difficulties which beset members of the profession But our task is to protect the public, and in a difficult case the first question in our minds must always be, 'Is it in the public interest to leave this man on the Register?' Nevertheless, subject always to that primary duty, members of the Disciplinary Committee may, and do, constantly put to themselves the further question 'What is the best thing for the man *himself*?'"

XLVII ON BEARING FARDELS

DEAR HUGH,

Do you remember writing to me—it must be a year nearly, so fast the time flies—about the Strike and what to think of it? I expect you have long ago forgotten, if not the Strike (and even that is fading) at least your letter, and that I did not reply. You trailed your coat a little, making the most of the arguments for downing scalpels, and obviously expected me to reply at once in my fieriest vein. I did in fact set out to do so, and had covered a page and a half before it became clear that I was stringing platitudes and stale slogans without conviction. I was no longer rock-hard sound on the National Health Service, and even began to find myself speculating irreverently

> Who would fardels bear
> When he himself might his quietus make
> With a small strike-kin?

It shook me to find my faith in the N.H.S. flawed. The N.H.S., or something very like it, was a dream of my youth—a dream compounded in part of highly unpractical Wellsian socialism, and in part of most practical disillusion (as patient and friend of patients, as houseman, and as locum) with private practice as I saw it in Redbrick in the 1930s. It was the kind of dream that was easy to dream in that frustrated decade, when ideals were fashionable only if they were impracticable. Among all the disappointments of the not-so-brave new world we came home to after the war, the N.H.S. seemed so nearly, in broad conception if not in detail (and hang the details, one said, they can be cleaned up later) the fulfilment of those dreams, that it is hardly to be wondered at that I enthused. Within reason, that is: you must not expect very loud fireworks from an academic pathologist. But I resigned from the B.M.A., made myself thoroughly unpopular with the local practitioners by raising the solitary dissentient voice at a meeting to protest about something or other, and might be heard holding forth at all hours to my fellow registrars round the draughty corridors of St. Ethelred's.

Moreover, I did well out of it. It doubled my salary overnight, and has doubled it again since. I was just at the right stage of my career, and perhaps just in the right specialty, to benefit maximally. I had not anticipated this with any exactness: my advocacy of the service was I believe wholly honest—wholly doctrinaire, if you will—but I cannot but admit in retrospect that the accelerated rise of my status and salary did nothing to hasten my disillusion afterwards. (Nor, to be altogether evenhanded, must I fail to admit a suspicion that my doubts coincide with a levelling of the rise of my pay, or that they may even be the onset of that middle-aged shift-to-the-right which afflicts opinions as much as polymorphs.)

Whatever the cause, and I believe it was not wholly intrinsic, I found myself at that moment of truth a year ago, when the Strike seemed imminent, no longer the convinced partisan I had been. I've tried several times, as the months slipped by since, to set down the why's and wherefore's. But each attempt seemed too much a compendium of all the plaintive letters in all the journals in these last years. What can one say new about the dismal registrar muddle, the unbuilt or half-built buildings, the wrongheadedness and boneheadedness of boards, the expense of spirit in a waste of interlocked buck-passing committees—all the infinity of oddments that can be smiled off so easily in detail but add up to so much ill. Let it suffice that for one at least of the service's most wholehearted enthusiasts this rose, like Hassan's, is faded, and this rose is bitter, and this rose is nothing but—the N.H.S.

Not *too* faded, or bitter. Don't let me exaggerate. I still believe in the N.H.S. A return to private practice on any large scale (except as a bludgeon in bargaining) I think would be a far worse catastrophe even than a whole-time salaried service (remind me to discuss with you some time—but it is another story—the subject of the dead hand of Harley Street in the London medical schools). But it seems to me that what began as the great and triumphant embodiment of a noble idea, the one first-class political invention of post-war England, has lived on that *one founding idea* and become *totally* sterile of new ones: that it is in danger of fossilisation into a stone-hard rigid structure that will sooner break than bend to the movements of time.

What's to do about it? Many things, probably; few of them easy to see clearly. But one single thing I believe will be found to lie not very far from the heart of the whole disease—the fact that what is essentially a medical matter is getting more and more out of medical control. Let me expound further.

Have you ever considered, Hugh, how great is the variation in the Parliamentary representation of the various professions? There are some, like the oldest, and the arts generally, and some others that are small or recent or of doubtful professional status, that are not officially represented in Parliament at all. There are others (the Services, Education, and Medicine) which are headed by Ministers, but by Ministers who are never active practitioners in, and rarely have ever belonged to, the professions they control. There are two, the Law and the Church, whose Parliamentary leaders are always leading and active practitioners of their profession, and which carry a number of tied seats in the Upper House. And perhaps for completeness we should include Politics, as the one profession that contrives always to remain its own master in all things.

Let us leave aside the woes of the minor professions, of *the Services* (*it seems to be agreed that we must keep the* troops out of politics) and the teachers (all demagogues fancy themselves pedagogues, anyway) and concentrate on the anomalous position of our own profession. For, as compared with the Church and the Law, it is clearly anomalous. These three are after all *the* three learned professions, very much of a muchness in most people's minds (for good or ill—

"I tell you, Mrs. Hadoway, the clergy live by our sins, the medical faculty by our diseases, and the law gentry by our misfortunes."

"Go not for every grief to the physician, for every quarrel to the lawyer, for every peccadillo to the priest, or every thirst to the pot.")

Let us leave out the archbishops too, lest we import irrelevant emotions, and stick to the comparison between Medicine and the Law. Three posts in every Government are reserved for successful lawyers—the Lord Chancellor, the Attorney-General, and the Solicitor-General. The Chancellor is at once the head of his profession and a Cabinet Minister: an arrangement which looks odd enough, if one chances to look at it with an unprejudiced eye, but which seems to work well enough in practice His is of course a political appointment, but he must be acceptable, in fact if not in the Constitution, to his fellow lawyers as well as to his fellow politicians Beyond these three Ministers, there are the dozen or so English Law Lords with safe seats in the Upper House True, in addition there is the Home Secretary, a layman with a finger in the Law's pie, but he is only the chief of the Law's ancillary services

We, in contrast, have no single smallest seat in any part of Parliament The few doctors in the Lower House have long left behind all active doctoring There are a few medical peers, but few reach that position while they are young enough to do any damage And that's all Nothing seems absurder to the Parliamentary machine than that the Minister of Health should be not, as now, an ambitious politician doing one of his rotating internships in hopes of promotion to a senior job later, but a real live doctor plucked from a thriving practice or popular lectern

Why? Why should we not have a Surgeon-General to run the N H S, helped by a Practitioner-General? And a Lord Great Physician in the Cabinet? And, say, the presidents of the seven Royal Colleges, ex officio, in the House of Lords? It's no less—or no more, if you prefer it that way—reasonable than the Law's quota of offices We matter as much in the world today as the lawyers

Considered soberly, perhaps the two Lower House appointments are not very practical—if only because it's hard to get into the Lower House if you have a proper job to do Perhaps it's not unreasonable to keep a lay Minister of Health, to do the quartermastering, the bricks-and-mortar and ancillary service side of the Health Service What we really need, however, is the medical equivalent of the Lord Chancellor—a Lord Great Physician or whatever you like to call him—a man chosen by the Prime Minister from the leaders of the profession, to have an assured place in the Government, not to run the N H S but to advise on all matters related to the health of the kingdom, and to act as a channel of communication between Government and profession With life peerages so nearly a reality, it is to be hoped that some active members of our profession (and others) will find their way into the Upper House it needs only that one of them be given an accepted status beyond mere membership of the house, and the thing is done

Nonsense, you say? Possibly But I do honestly believe that, now the fate of the profession is so firmly in the hands of the State, no Government will succeed in maintaining happy relations with us till it takes unto itself a colleague who is a doctor—not a politician who was once a doctor—who can talk to both sides from the inside We will not indefinitely tolerate the rule of an administration in which we have no representation

Right at the bottom, in the wards and surgeries and laboratories, we still run our own show As you climb up the hierarchical pyramid to the Minister sitting on the apex, the proportion of laymen rapidly rises, reaching 100% a step or two below the top And the proportion at medium levels, already far too high, is increasing Have you ever noticed how small we bulk in the official publications on the N H S? We forget that we form little more than 10% of its employees The five-day-a-week clerks and porters and boilermen, not to mention the more dedicated ancillaries like nurses and lab-men and physiotherapists, so greatly outnumber us that to the administrators we are an insignificant minority, and a touchy and expensive minority at that, best dispensed with as far as possible Put it at its lowest, we aren't many votes But just as we are in danger of forgetting our numerical insignificance, there's even more danger that the Ministry and all its scattered deputies, absorbed in the renovation of hospital laundries and the pay of spectacle-fitters, will forget that this 10%, in the last analysis, is the one wholly indispensable part of the whole service It's necessary to say, what no-one will say for us, and what we are too apt to understate ourselves, that all the vast and complex structure—wards, clinics, and ambulance services, matrons and mortuary keepers, pharmaceutical firms and Friends of Fairforfechit Cottage Hospital—without us the whole bang lot would be as much use as a chain of medieval lazarhouses

> This is our master, famous, calm and dead,
> Borne on our shoulders

—not very calm and not quite dead yet, but indubitably *borne on our shoulders*

Medicine in the last two hundred years has come into the very forefront of the influences that make a safe life possible to civilised man, and, whatever ideas we may have pinched from other sciences on the way, it is we—a mere half-dozen or so generations of doctors—who have done it And it is still we, and we alone, who can keep it working (Consider, for a moment, to reduce the whole matter to its starkest terms, in whose hands you'd rather be if you had an acute abdomen—two average general practitioners with an old black bag and a kitchen table, or all the non-medically-qualified scientists in the service of the M R C and I C I together, with the best operating-theatre money could buy and the College of Nursing for good measure?) The N H S is no more and no less than a machinery for facilitating the work of its doctors It does no single thing of any value that does not trace back finally to a doctor saying, "Here is a patient of mine this is what must be done if he is to get well and stay well" But we have acquired a colossal administrative tail, a tail that is so large and long and heavy that it begins to think it can wag the dog And that's bad, not only for us but for the whole community whose health is in our hands

There is now a limit of 25% on the medical membership of regional boards It ought to be a minimum of 51% If the present trend continues, the 25% will in time fade to the occasional invited attendance of a single non-voting medical nominee, who will probably be frisked for stethoscopes before he is allowed to enter the boardroom, and made to change his clothes lest he brings the least whiff of the wards or sickroom with him

It is natural enough for the lay administrator to find his medical colleagues difficult The better they are, the more likely are they to have accepted their administrative duties as a disagreeable necessity whose formalities, office hours, and proper channels they treat with improper levity They are insatiably rapacious in their demands for staff and space and equipment, large and airy in their plans, querulous over delays, argumentative to the last degree (among themselves as well as with others), and exceedingly expensive to pay The prospect of any such woolly-headed and extravagant enthusiasts being permitted to run their own show is clearly an administrative nightmare "the country would be bankrupt in a week"

I offer to such the example of the universities The universities are the most successful invention of Western civilisation—indeed, perhaps, its key invention They are of incredible robustness outside the Churches, I can think of only two extant institutions, the British Crown and the Icelandic Thing, that can pretend to any real continuity of life as long as the dozen oldest European universities They are adaptable to all societies the world is full of them now, and the state of its universities is the best test of the civilisation of a country They are nearly always on the verge of bankruptcy—Marlowe knew the truth of it when he wrote

> And to this day is every scholar poor,
> Gross gold from them runs headlong to the boor

But they thrive on it, and with them thrive the societies which they fertilise And the secret? They are run always by amateurs, inefficiently often and argumentatively always, but with enthusiasm and vision and a real understanding of what they are there for and in the long run that matters infinitely more than administrative efficiency Chinese universities, and with them Chinese civilisation, fossilised when the emperors came to set the exam papers But what Civil Servant, starting to devise a university from scratch, would not prefer the Chinese model?

Perhaps you won't accept the analogy between university administration and N H S administration True, they have been made very differently But that may be the N H S 's loss

Time I stopped I could go on at length—remember there is a full year's reappraisal behind this letter—but I think I've let free most of the new bees in my bonnet And you can reassure Mr Mr —what is this week's Minister of Health called?—that I'm not angling for the appointment of Lord Great Physician for myself yet, though if my cerebral arteries are still in full flood I might change my mind in twenty years' time I don't mind offering him a slightly unconventional list for the first medical life peerages, though, if he's interested

I offer you a new watchword—No Administration without Representation!

Yours,
PETER DAVEY

Public Health

Towards Clean Air

Some provisions of the Clean Air Act have been in force for some time [1], and the remainder were brought into force last Sunday, June 1 It is now an offence, punishable by fine, for dark smoke to be emitted from any chimney in England and Wales In a memorandum to local authorities [2] the Ministry of Housing and Local Government points out that measures to reduce smoke will often result in substantial saving of fuel The National Industrial Fuel Efficiency Service surveyed 555 Lancashire boilers and found that installation of economisers and mechanical stokers should raise the efficiency of these boilers to at least 75% of the net calorific value of the coal N I F E S estimated that the expenditure on these modifications would be recouped in about a year by the saving in fuel costs

---

In England Now

A Running Commentary by Peripatetic Correspondents

SINCE our translation to an outpost of Empire we have become steadily more sophisticated, and nothing much surprises us any more True, we have not yet ceased to react pleasurably at the sight of a flock of green parrots sitting on the roof of the physiology department, and the undoubted presence of scorpions in the sand outside anatomy still induces a delightful gooseflesh in our sandalled feet But when a ghastly tumult breaks out over our heads in the middle of a tutorial we no longer turn pale and falter, for we recognise the characteristic sound of possums pursued by the animal-house cat We have grown accustomed to lecturing to dogs of all shapes and sizes, sometimes curled up in the one and ninepennies, and sometimes crouched under the lecturer's bench, ready to spring The other day one of them—a black-and-white spotted affair—got up in the middle of our lecture, yawned widely, and stalked out We did not even blink

Nevertheless our new community lecture theatre has given us pause The room doubles as a histology laboratory, and is therefore long and flat, in contrast to the precipitous cliffside we were wont to confront Indeed, it is only on exceptionally clear days that we can see the back bench from the dais The roof is low and the temperature high, a circumstance dictating the opening of windows which admit the full roar of the heavy traffic and the happy screams of the patrons of the bathing beach outside We have all become hoarse in the attempt to transfer the cargo of our overburdened minds to the keeping of our young friends in the back row, but our biochemist has finally cracked under the strain, and we are waiting for a public address system which will allow us to address the multitude at the cost of fewer petechial hæmorrhages In the meantime our electrophysiologist has kindly rigged us up an imposing assembly of apparatus which subserves roughly the same purpose We have a rickety microphone which we clutch feverishly to our teeth, and our thoughts pass through two black metallic boxes under the bench to a loud-speaker placed on the floor close to the door—an object of keen scrutiny from our canine visitors

In the first box, as in all electronic apparatus we have met, there is a bewildering array of knobs, in this case freely labelled with slogans like "Bass up", "Record", or "Tone", which we take to be Hi-Fi stigmata If we injudiciously leave the microphone to its own devices while we write on the blackboard, it yells and howls till we get back to it again and can twiddle one of the knobs to calm it We are not very good at electrons, but our genial electrophysiologist has given us a thorough coaching on which knob to turn For a time all went well, but our undoing came yesterday, when in the heat of one of our impassioned perorations we arrogantly turned a knob without bending down to make the vital identification Instantly the loudspeaker began to pour forth a stream of abstruse biochemical information, delivered in the voice of our ingenious biochemist and amplified to several thousand decibels

It was not until morning tea that we stopped twitching sufficiently for it to be explained to us slowly and carefully that the *second* black box contained a tape-recorder

* * *

Penny plain or two bucks coloured. I'm green with envy at the Yanks Why should we be stuck to black and white for our passport photographs, while they are allowed to grin at us in glorious 'Technicolor' this year? Our Secretary of State for Foreign Affairs is either getting fuddy-duddy about contemporary British art, or is too allergic to the political implications of the paintbox The best excuse he can give us is that the colours will fade before the passport expires in ten years We work the other way round A glance in the mirror leaves no doubt which of us is fading the faster

If I were not such a shy and modest man, I should say that it would need the genius of a Turner to do full justice to the spectrum in my shaving mirror It presents a worthy chalenough, if one chances to look at it with an unprejudiced eye, but which seems to work well enough in practice His is of course a political appointment, but he must be acceptable, in fact if not in the Constitution, to his fellow lawyers as well as to his fellow politicians Beyond these three Ministers, there are the dozen or so English Law Lords with safe seats in the Upper House True, in addition there is the Home Secretary, a layman with a finger in the Law's pie, but he is only the chief of the Law's ancillary services

We, in contrast, have no single smallest seat in any part of Parliament The few doctors in the Lower House have long left behind all active doctoring There are a few medical peers, but few reach that position while they are young enough to do any damage And that's all Nothing seems absurder to the Parliamentary machine than that the Minister of Health should be not, as now, an ambitious politician doing one of his rotating internships in hopes of promotion to a senior job later, but a real live doctor plucked from a thriving practice or popular lectern

This is our master, famous, calm and dead,
Borne on our shoulders

—not very calm and not quite dead yet, but indubitably *borne on our shoulders*

Medicine in the last two hundred years has come into the very forefront of the influences that make a safe life possible to civilised man, and, whatever ideas we may have pinched from other sciences on the way, it is we—a mere half-dozen or so generations of doctors—who have done it And it is still we, and we alone, who can keep it working (Consider, for a moment, to reduce the whole matter to its starkest terms, in whose hands you'd rather be if you had an acute abdomen—two average general practitioners with an old black bag and a kitchen table, or all the non-medically-qualified scientists in the service of the M R C and I C I together, with the best operating-theatre money could buy and the College of Nursing for good measure?) The N H S is no more and no less than a machinery for facilitating the work of its doctors It does no single thing of any value that does not trace back finally to a doctor saying, "Here is a patient of mine this is what must be done if he is to get well and stay well" But we have acquired a colossal administrative tail, a tail that is so large and long and heavy that it begins to think it can wag the dog And that's bad, not only for us but for the whole community whose health is in our hands

There is now a limit of 25% on the medical membership of regional boards It ought to be a minimum of 51% If the present trend continues, the 25% will in time fade to the occasional invited attendance of a single non-voting medical nominee, who will probably be frisked for stethoscopes before he is allowed to enter the boardroom, and made to change his clothes lest he brings the least whiff of the wards or sickroom with him

It is natural enough for the lay administrator to find his medical colleagues difficult The better they are, the more likely are they to have accepted their administrative duties as a disagreeable necessity whose formalities, office hours, and proper channels they treat with improper levity They are insatiably rapacious in their demands for staff and space and equipment, large and airy in their plans, querulous over delays, argumentative to the last degree (among themselves as well as with others), and exceedingly expensive to pay The prospect of any such woolly-headed and extravagant enthusiasts being permitted to run their own show is clearly an administrative nightmare: "the country would be bankrupt in a week".

I offer to such the example of the universities. The universities are the most successful invention of Western civilisation—indeed, perhaps, its key invention. They are of incredible robustness: outside the Churches, I can think of only two extant institutions, the British Crown and the Icelandic Thing, that can pretend to any real continuity of life as long as the dozen oldest European universities. They are adaptable to all societies: the world is full of them now, and the state of its universities is the best test of the civilisation of a country. They are nearly always on the verge of bankruptcy—Marlowe knew the truth of it when he wrote

> And to this day is every scholar poor,
> Gross gold from them runs headlong to the boor.

But they thrive on it, and with them thrive the societies which they fertilise. And the secret? They are run always by amateurs, inefficiently often and argumentatively always, but with enthusiasm and vision and a real understanding of what they are there for: and in the long run that matters infinitely more than administrative efficiency. Chinese universities, and with them Chinese civilisation, fossilised when the emperors came to set the exam papers. But what Civil Servant, starting to devise a university from scratch, would not prefer the Chinese model?

Perhaps you won't accept the analogy between university administration and N.H.S. administration. True, they have been made very differently. But that may be the N.H.S.'s loss.

Time I stopped. I could go on at length—remember there is a full year's reappraisal behind this letter—but I think I've let free most of the new bees in my bonnet. And you can reassure Mr   Mr   —what is this week's Minister of Health called?—that I'm not angling for the appointment of Lord Great Physician for myself yet, though if my cerebral arteries are still in full flood I might change my mind in twenty years' time. I don't mind offering him a slightly unconventional list for the first medical life peerages, though, if he's interested.

I offer you a new watchword—No Administration without Representation!

Yours,
PETER DAVEY

Public Health

Towards Clean Air

Some provisions of the Clean Air Act have been in force for some time[1], and the remainder were brought into force last Sunday, June 1. It is now an offence, punishable by fine, for dark smoke to be emitted from any chimney in England and Wales. In a memorandum to local authorities[2] the Ministry of Housing and Local Government points out that measures to reduce smoke will often result in substantial saving of fuel. The National Industrial Fuel Efficiency Service surveyed 555 Lancashire boilers and found that installation of economisers and mechanical stokers should raise the efficiency of these boilers to at least 75% of the net calorific value of the coal. N.I.F.E.S. estimated that the expenditure on these modifications would be recouped in about a year by the saving in fuel costs.

In England Now

A Running Commentary by Peripatetic Correspondents

SINCE our translation to an outpost of Empire we have become steadily more sophisticated, and nothing much surprises us any more. True, we have not yet ceased to react pleasurably at the sight of a flock of green parrots sitting on the roof of the physiology department, and the undoubted presence of scorpions in the sand outside anatomy still induces a delightful gooseflesh in our sandalled feet. But when a ghastly tumult breaks out over our heads in the middle of a tutorial we no longer turn pale and falter, for we recognise the characteristic sound of possums pursued by the animal-house cat. We have grown accustomed to lecturing to dogs of all shapes and sizes, sometimes curled up in the one and ninepennies, and sometimes crouched under the lecturer's bench, ready to spring. The other day one of them—a black-and-white spotted affair—got up in the middle of our lecture, yawned widely, and stalked out. We did not even blink.

Nevertheless our new community lecture theatre has given us pause. The room doubles as a histology laboratory, and is therefore long and flat, in contrast to the precipitous cliffside we were wont to confront. Indeed, it is only on exceptionally clear days that we can see the back bench from the dais. The roof is low and the temperature high, a circumstance dictating the opening of windows which admit the full roar of the heavy traffic and the happy screams of the patrons of the bathing beach outside. We have all become hoarse in the attempt to transfer the cargo of our overburdened minds to the keeping of our young friends in the back row, but our biochemist has finally cracked under the strain, and we are waiting for a public address system which will allow us to address the multitude at the cost of fewer petechial hæmorrhages. In the meantime our electrophysiologist has kindly rigged us up an imposing assembly of apparatus which subserves roughly the same purpose. We have a rickety microphone which we clutch feverishly to our teeth, and our thoughts pass through two black metallic boxes under the bench to a loud-speaker placed on the floor close to the door—an object of keen scrutiny from our canine visitors.

In the first box, as in all electronic apparatus we have met, there is a bewildering array of knobs, in this case freely labelled with slogans like "Bass up", "Record", or "Tone", which we take to be Hi-Fi stigmata. If we injudiciously leave the microphone to its own devices while we write on the blackboard, it yells and howls till we get back to it again and can twiddle one of the knobs to calm it. We are not very good at electrons, but our genial electrophysiologist has given us a thorough coaching on which knob to turn. For a time all went well, but our undoing came yesterday, when in the heat of one of our impassioned perorations we arrogantly turned a knob without bending down to make the vital identification. Instantly the loudspeaker began to pour forth a stream of abstruse biochemical information, delivered in the voice of our ingenious biochemist and amplified to several thousand decibels.

It was not until morning tea that we stopped twitching sufficiently for it to be explained to us slowly and carefully that the *second* black box contained a tape-recorder.

* * *

Penny plain or two bucks coloured. I'm green with envy at the Yanks. Why should we be stuck to black and white for our passport photographs, while they are allowed to grin at us in glorious 'Technicolor' this year? Our Secretary of State for Foreign Affairs is either getting fuddy-duddy about contemporary British art, or is too allergic to the political implications of the paintbox. The best excuse he can give us is that the colours will fade before the passport expires in ten years. We work the other way round. A glance in the mirror leaves no doubt which of us is fading the faster.

If I were not such a shy and modest man, I should say that it would need the genius of a Turner to do full justice to the spectrum in my shaving mirror. It presents a worthy challenge to any manufacturer of colour films, a kaleidoscope of delight to any emigration officer Just imagine the artistic sensitivity of the emulsion to capture that cyanotic tinge in the ear lobes, the turgid pink of nasal mucosa flashing beneath the beacon of acne rosacea, and tell-tale stains of nicotine Hyperpiesia has achieved such a pretty colour gradation down the *venetian blind slats of my treble chins, something* approaching the rainbow lighting of a cinema curtain when the organ goes down A turkey's wattles are hardly a polite *comparison* That telangiectasis across the bridge of the nose is a bit of a blot, but the weight of presbyopia made it an inevitable concomitant of this clonal fading process I do wonder if the new films would bring out the mascara-like subtleties of those drooping suborbital pouches, and record for posterity the silvery current tidemark of an ebbing hair-line

Yes, we could bring a lot more colour into the drab corridors *of London* Airport and Southampton How the emigration officers would be tempted to linger over their matching cards and lovibond comparators with some glorious pin-up bird of paradise It is time that we British showed our true colours to the world

* * *

" She's my sugar " was a favourite saying when I was a student, and I have always liked the American use of " honey " as a term of endearment How great my pleasure, then, to find these sweet influences seeping into scientific medicine Today I was handed the summary of a report and read " E E G The sugar shows some asymmetry between the two hemispheres but no definite focal lesion or paroxysmal features " Dear girl, bless her heart

* * *

The only place where all departments of our teaching hospital come together is in our colour-slide club For clinical occasions we can rarely persuade a physician to attend a surgical gathering, but once a month we all assemble, peacefully yet critically, to gaze at one another's transparencies Here character comes out and we see our colleagues in their true colours, and it is instructive to note how closely photographic technique mirrors specialist inclination

Our radiologist's habitual underexposures betray the many hours he spends in darkened rooms The surgeons are not surprised that our most investigative-minded physician submits pictures so cluttered with detail that the point is lost The latter might well retort that the indiscriminate tendency of one or two surgeons to lop off heads and limbs reflects their operative hamhandedness It seems most appropriate that the pathologists favour still-lifes Red seems to dominate most slides taken by our blood-and-thunder dentist We also have an endocrinologist who is rather interested in sex reversal, and it is sometimes difficult to recognise his subjects But we all agree *that the radiographers take the best pictures*

YEHUDI MENUHIN AT THE BATH FESTIVAL

The abbey is filled
The cold surround of funerary plaques
Draws warmth where living listeners
Lean for support against the stiff names of the dead
The body of the church wakes, waiting now to find its soul,
And a stilled torrent of attention
Presses upon one man
So normal, outwardly Everyman, anonymous,
He waits in a lit glade of the choir
Beneath a shadowed forest of fan vaulting
Until the moment calls
The inward person stirs, sketches his signature
In a small, intimate gesture, his face laid close against his instrument,
Then, lost in music, man and violin forget their separate selves
The bow, a slim glint of light, thrusts like a rapier,
The left hand curves in a question mark,
Fingering the unseen
Infinitesimally slender, infinitely tensile,
Heaven and earth are laced together on a single thread of sound

Letters to the Editor

THE RUSSIAN VACCINE

SIR,—The recent publicity given *to the* " Russian vaccine " in the House of Commons and in the Press has already produced a series of anxious inquiries from those afflicted with multiple (disseminated) and other forms of sclerosis I am sure that I am not alone in having had to conduct a number of difficult interviews with patients or with their friends in order to explain what little is known about the vaccine and in order to set out some sort of balance-sheet so that *patients may decide whether or not* to spend the twenty-five pounds for the single course or the seventy-five pounds for *the triple course advocated by* the proponents of the Margulis-Shubladze vaccine

I have been following (by correspondence) the fortunes *of* this particular regime *for* some two years I have approached the problem with a fairly strong negative bias—a bias amplified by the recent report from Belfast by Professor Dick [1] that the vaccine is very largely related to *rabies* The directions which accompany the vaccine also give very little confidence in its efficacy, for the gist *of these* instructions is as follows

An intradermal skin test is carried out If it is negative treatment is carried out subcutaneously If there is a positive skin reaction then it is suggested that an intracutaneous method of treatment should be practised Repetition of the prescribed courses is advised, and it is suggested that on an average it should be repeated once each year The treatment should not be given to well-established cases of disseminated sclerosis but only those in which there are minor and preferably sensory manifestations The appearance of new symptoms is not regarded as a contraindication for the continuation of the treatment The first sentence of the final paragraph of the instructions is eccentrically interesting, for it says baldly " A separate needle is used for each patient " Professor Shubladze is careful to state that the course of injections brings about a cure *of only a third of the number of* patients treated

The American Multiple Sclerosis Society have also investigated the existing evidence about the vaccine, and their opinion is expressed in the following terms

" The fragmentary results of treatment available at present indicate that the vaccine of Margulis-Shubladze is not curative nor does it prevent any exacerbation even while being given "

Further, in January, 1957, Dr F Lhermitte of the *Salpetrière wrote*

" Nous avons en effet utilise le vaccin soviétique dans quelques cas de Sclérose en Plaques Les résultats que nous avons obtenus sont encore trop recents pour que nous puissions porter un jugement définitif, mais ils ne semblent guère encourageants "

On the other side of the balance-sheet the evidence of the alleged efficacy of the treatment comprises the statements which have appeared in the public Press, a series of rumours which are relayed to us by our patients, and the Russian makers' own claim that a third of the patients are cured (It may be mentioned in passing that McAlpine et al [2] state that in 9 out of every 10 patients the disease runs a remitting course in the initial stages) It is, of course, possible that more controlled scientific information already exists in the Russian literature and is as yet undisclosed to us

From the scientific point of view one would have wished that an official statement on this subject could have been made either in the Press or in *Parliament,* but one *has to* recognise that disseminated sclerosis is a condition attended by unique emotional overtones and capable of engendering remarkable pressure groups. Whether we like it scientifically or not a number of patients are going to insist on having courses of the vaccine even at the expense of importing it themselves. Indeed it may well be urged that it is only right that they should be able to choose the way in which they spend their money (though not, of course, on "cures for cancer"). In any case the medical community is going to be drawn into the matter, since the Russian pamphlet on the subject and the official statements insist that the courses of the vaccine should be recommended by doctors and administered by them. It would be more satisfying if we knew that an official double-blind trial were going to be undertaken, but it must be admitted that no prima-facie case can be made out either for the diversion of effort or for the expenditure of the money required. In the event, therefore, it seems very likely that very small groups of patients of quality unselected, except by their determination to try something new, are going to receive somewhat irregular treatment in various parts of the country. No doubt a great deal of psychological, social, and even symptomatic benefit will accrue, but there is only a very slender possibility that real scientific information will be accumulated unless a single rigid criterion is applied to all cases. The assessment and recording of remissions in these circumstances is quite useless. At the risk of being accused of presumptuousness I should like to put forward the notion that all who may be led to administer the vaccine treatment should keep a record solely of the relapse-rate, for this can be the only real criterion of the efficiency of a vaccine treatment. After a period of 5–10 years these figures could either be made available to the Multiple Sclerosis Society or published in the medical Press. The work of Muller[3] and of McAlpine et al[2] already provides an excellent control study of this relapse-rate, and for the purpose of assessment McAlpine's definition of relapse is worth quoting.

THROMBOSIS OF THE INTERNAL CAROTID ARTERY

SIR,—I much enjoyed the article of May 24 by my friends and former colleagues, Dr Clarke and Mr Harris, on internal-carotid thrombosis simulating intracranial tumour, and they have made a valuable contribution to the clinical evaluation of this difficult and often elusive condition.

At Ashford I have recognised 15 cases of internal-carotid occlusion complete and incomplete in the past three years, and in 3 of these the clinical appearance was that of cerebral tumour, the correct diagnosis being made only after carotid angiography. In 1 of these patients angiography was followed by increase in the aphasic and hemiplegic disability, and with Dr Clarke and Mr Harris I am still concerned about the possible risks of this investigation in carotid occlusion.

While agreeing with them that thromboendarterectomy or operative replacement of the carotid artery may be the treatment of choice, I think they are a little pessimistic about the value and the dangers of anticoagulant drugs in this condition. I have been using these for certain types of cerebral infarction since 1954, and one indication has been where the infarction is associated with carotid occlusion. I consider their value lies in preventing distal embolism from the carotid thrombus and in controlling to some extent the distal propagation of thrombosis as described in Dr Clarke and Mr Harris' second case. My experience has also been that the dangers of intracranial bleeding from anticoagulant therapy after any cerebral infarction is greater in theory than in practice, and my necropsy material has shown no increase in hæmorrhagic infarctions in patients treated with anticoagulants.

I believe that their best use lies in the first stage of the development of the clinical picture when the appearance of focal symptoms is progressive or intermittent.

One of the valuable points that Dr Clarke and Mr Harris make is their emphasis on cerebral œdema in massive infarction of the brain, and they rightly suggest that treatment of this œdema may reduce mortality and morbidity. I have used short courses of corticosteroid therapy intravenously and intramuscularly in this second or acute phase of carotid thrombosis in an attempt to control the response of the cerebral circulation to infarction, but my experience has been too small to assess the value of this method up to now. However, in view of the fact that 1 in every 3 or 4 patients dies from this condition, and half the survivors have a severe and permanent disability, it may be advisable to consider the use of anticoagulants and corticosteroids in those patients considered unsuitable for surgery.

Ashford Hospital,
Ashford, Middlesex

A. BARHAM CARTER.

CEREBRAL PALSY

SIR,—The letter in your issue of May 3 by Dr Mac Keith and Dr Polani illustrates the difficulty of finding an exact overall definition of infantile cerebral palsy. Throughout the country, many non-medical voluntary bodies are using the word in its widest sense and include all cases of defect of movement due to a cerebral cause. Thus a considerable number of cases that in the past have been labelled crudely as "mental defectives" are now labelled "cerebral palsy" or "spastic".

It is suggested that there are cases of cerebral palsy coming within the precise definition given in the letter that have "certain special motor, intellectual, and emotional difficulties in common and so have certain special therapeutic and educational needs". The definition includes a wide range of cerebral disorders in children, and I would query the statement that they have these specific needs in common. There is a profound difference in the needs of an intellectually normal athetoid with poor ability in the hands and difficulty with walking, and a hemiplegic child with good use of one hand and near normal walking but often suffering from epilepsy and having a lowered intelligence. (May I refute from concrete experience the statement in your leader of April 19 that "it is of little use to train a child to use a limb that he cannot feel"? A hand with marked astereognosis can be used with training and encouragement as a useful assisting hand and give the child an outwardly normal appearance.)

From the Bristol Cerebral Palsy Clinic we have recommended the placement of children in ordinary schools, E.S.N. schools, schools for the deaf and for speech disorders, and for the physically handicapped, occupation centres, mental-deficiency hospitals, for the home teacher service as well as to special units for cerebral-palsied children—some day and some residential, according to need. A few of our children are doing well in ordinary grammar schools. The therapeutic programme also varies from child to child.

From the angle of research, it does not seem desirable to exclude cases that do not come within the definition. I agree with Dr Crawford (May 17) that the term quantitative disorders of movement in mental defectives is misleading. In mental-deficiency hospitals there are cases of abnormal rigidity and bizarre movements, which cannot be called quantitative only For example, there is a case of phenylpyruvic oligophrenia walking in severe equinus, even after bilateral elongation of tendo-Achillis operation There are several members of one family with an identical motor defect, at present ill-defined These cases are on the periphery of the subject, but knowledge can be lost if they are not included Some interesting cases of speech disorder, such as congenital suprabulbar palsy and executive aphasia, could justifiably be included under the heading of cerebral palsy

---

[3] Muller, R. *Acta med. scand.* 1949, 133, suppl. 222

There is evidence that some birth-injured cases deteriorate mentally Epilepsy may commence at any age It is doubtful if the use of the words "not progressive" in the definition is clinically exact

There is a need for cerebral-palsy assessment clinics to arrange treatment and education for these children and to do long-term research I feel the title should be loosely interpreted as a "motor defect in children due to a cerebral cause", so that all doubtful and borderline cases can be seen, and in this way precise clinical syndromes and patterns will emerge

KETOGENIC ACTION OF HUMAN ANTERIOR PITUITARY IN DIABETIC BABOONS

SIR,—We were much interested in the ketogenic effect of human growth hormone in normal and in diabetic, hypophysectomised subjects, reported by Ikkos et al (April 5)

During the past few years we have been studying various endocrine factors controlling the lipæmia (including cholesterolæmia), ketonæmia, and hyperglycæmia of pancreatectomised, insulin-deprived baboons Removal of the hypophysis from pancreatectomised baboons abolishes the severe lipæmia and prevents the ketosis but does not affect the hyperglycæmia [1] The administration of cortisone to pancreatectomised-hypophysectomised baboons results in the development of a lipæmia even more severe than that in the pancreatectomised baboon before hypophysectomy,[2] but is not associated with a ketosis The administration of acetone-dried human anterior pituitary to pancreatectomised-hypophysectomised baboons intensifies the hyperglycæmia and results in severe ketosis unaccompanied by lipæmia The complete diabetic picture in the pancreatectomised-hypophysectomised baboon can be produced only by the administration of cortisone in conjunction with crude pituitary extract It should be mentioned that crude human anterior pituitary produces severe toxic effects, leading to a high mortality in pancreatectomised-hypophysectomised baboons deprived of insulin In these circumstances the insulin requirements of the baboon are greatly increased The administration of twice the amount of crude human anterior pituitary to normal baboons failed to affect the blood-sugar or to produce a ketosis

It is thus apparent that in the pancreatectomised baboon the lipæmia depends on the degree of functional activity of the adrenal cortex, and the severity of the ketosis is related to the presence of some factor in the anterior lobe of the pituitary and is not determined by the gravity of the lipæmia Our studies show that human anterior pituitary is ketogenic for the pancreatectomised-hypophysectomised baboon no less than it is for the hypophysectomised human diabetic patient

DEATH OF A BOXER

SIR,—My own experience of the effect of injury on the brain derives from animal experiments, and it leaves me convinced that very few doctors realise 'how extremely vulnerable the brain is to physical injury In the anæsthetised animal, for instance, once the dura is opened it is practically impossible to touch the surface of the brain without causing sub-pial hæmorrhage at the point of contact and a much more extensive zone of persistent traumatic œdema and ischæmia which must kill thousands of neurones '

If more direct evidence is needed, may I quote from an article by Mr J H Doggart [1] on the impact of boxing on the visual apparatus? Mr Doggart mentions the case of a professional who gave up boxing after a training bout in which he was punched into a mental twilight for three days The boxer is quoted [2] as saying "I wanted to leave the game that had threatened my sanity before I met with an accident in a real fight with six-ounce gloves that would permanently hurt my brain" A weakling, lacking in courage, endurance, skill, character? Unable to stand up and face both physical and moral stresses? Not of the bulldog breed? Well, no—not exactly His name was Tunney and he had twice defeated Jack Dempse

I believe that the end of boxing would be hastened the public were aware of the damage that it causes Fro time to time the individual doctor has tried to do th public service and has failed because the job is too b for any individual May I therefore conclude by repeati my question in a slightly different form? Has any med cal research council, college, society, or other organise body of medical experts ever made any serious attem to marshal the facts about boxing, put them in fro of the public, and keep them there? And if no why not?

HOOKWORM AND ANÆMIA

SIR,—The letter of April 19 from Dr Meiklejohn an Dr Passmore on the subject of hookworm anæmia bring timely notice to the need for adequate study of this subjec

The improvement of microchemical techniques, and particu larly the advent of radioactive tracer methods during the las decade, have given a new impetus to the study of the disease

Here, in Malaya, we see a great deal of anæmia and hookworm infection, and we are also fortunate in possessing a tracer laboratory Attempts to study the association between hookworm infection and anæmia are under way, but progress is slow because of the limited man-hours available in a small team

Using ^{51}Cr to estimate blood-loss, I have found, in the eight patients with *Necator americanus* infection studied so far, that the blood-loss was remarkably constant, being about 0 1 ml blood per worm per day, a loss which dropped to a fraction after a vermifuge Two of these patients had losses of over 80 ml of blood each day These losses appear larger than in the twelve patients studied by Roche et al [3] using the same methods Estimations of actual iron losses using ^{59}Fe are under way, as are also the problems of iron absorption

Referring to the possibilities of hæmodilution in severe anæmia with hookworm infection, I have estimated the plasma volume with Evans-blue in ninety-six patients These patients had hæmoglobin levels ranging from normal down to 2 g per 100 ml, the anæmic patients were all suffering from iron deficiency usually associated with hookworm infection, the

---

1 Doggart, J H *Arch Ophthal, N Y* 1955, 54, 161
2 Carroll, E J *Amer J med Sci* 1936, 191, 706
3 Roche, M, Perez-Gimenez, M E, Layrisse, M, Prisco, E D *J clin Invest* 1957, 36, 1183

mean blood-volume in those with normal hæmoglobin levels was about 4500 ml, and when the anæmia was severe it dropped to about 2500 ml This diminution of blood-volume was due to a fall in the red-cell volume, the plasma volume remained unchanged.

In my opinion, the study of the anæmia is of secondary importance in hookworm disease, more attention should be paid to such intestinal factors as worm load and the availability, absorption, and losses of iron.

As Dr Meiklejohn and Dr Passmore state, the time is opportune for the organisation of a "properly financed research project" for the study of this disease.

P W G TASKER.

POSTMATURITY

SIR,—One cannot adopt Mr Wrigley's plan (May 31, p 1167) for the management of postmaturity on the basis of a low induction-rate or the absence of fœtal deaths due to intracranial trauma With the present conflicting evidence on this subject it is easy to develop an "obstetrical rationale" to suit any plan of management. One must give evidence of an overall reduction in fœtal mortality or a reduction in postmature stillbirths without a comparable rise in stillbirths in induced patients before a plan becomes acceptable

Mr Wrigley admits the variation in fœtal size at one period of gestation, and then uses this as a gauge of maturity In addition, clinical assessment of fœtal size is sometimes inaccurate. One admits the anatomical bogy of a large postmature fœtus which requires careful obstetric management to save its life What, however, is the magnitude of the risk of allowing a large baby to remain in the uterus after the fortieth week of gestation? There is very little growth of the fœtal skull after term, and when the fœtus is large many obstetricians would prefer to keep the membranes intact if cephalopelvic disproportion is possible

Mile End Hospital,

INFLUENCE OF LIGHT ON THE HYPERBILIRUBINÆMIA OF INFANTS

SIR,—May I make a few points in connection with the article by Dr Cremer and his colleagues (May 24)?

In 1957 Dr (now Prof) G H Lathe brought to our notice at Queen Charlotte's Maternity Hospital the suggestion by Perryman that sunlight and light-blue fluorescent discharge tubes could reduce bilirubin-levels in vitro and in vivo The team engaged in the study of hyperbilirubinæmia therefore decided to try the effect of exposure to 24-in. light-blue fluorescent 40-watt discharge tubes (G E C.) on a group of babies, mainly prematures, whose bilirubin-levels exceeded 10 mg per 100 ml on the third or fourth days of life.

The time of exposure varied but the bilirubin levels dropped in ten out of twelve cases, the rise in the remaining two being 0 3 and 0 4 mg per 100 ml The change, being less than 2 5 mg per 100 ml. in eleven of the cases, was within the range of experimental error, but the absence of a serious rise in any case looked promising In six out of thirteen controls selected on the same basis as the treated cases there was a rise from 1 mg to 4 2 mg in the comparable period. The team would agree with Dr Cremer and his colleagues that this form of light treatment is probably effective in halting the increase in serum-bilirubin level, although our figures are less convincing, probably because exposure was intermittent We believe that the source of light would have to be greatly strengthened if bilirubin was to be controlled in the presence of active hæmolysis

This work has been dropped for the present for two main reasons firstly, because there is no information about the nature or toxicity of the material elaborated from bilirubin by the action of these light waves, and secondly, because it seems unlikely that the quantitative effect will be great enough to be a substitute for exchange transfusions The treated and untreated cases will be reviewed one year after the last treatment and a short detailed report may then be presented.

Meanwhile, the Queen Charlotte's team feels that the task before them is to improve the technique of exchange transfusion, to try to refine further the indications for treatment both in hæmolytic disease of the newborn and in the very rare cases of prematurity at risk of kernicterus, and to seek methods for hurrying the conjugation of bilirubin into its excretable form

While many workers, clinical, laboratory, and nursing, were involved in this trial, mention must be made of Mr C R J Ruthven, the biochemical technician responsible for the large number of bilirubin estimations required

London, W 6

ALFRED WHITE FRANKLIN

THE NATURAL HISTORY OF CHRONIC BRONCHITIS

SIR,—The points I wish to make about the admirably written paper by Dr Reid and Dr Fairbairn (May 31) are mainly based on a report which I submitted to the heads of my department (the Treasury) in January, 1957, and which is unpublished.

Although this report was not available to Dr Reid and Dr Fairbairn, I had opportunity to discuss some of its contents with them on several occasions In 1947 I attempted, with the help of the late Dr C G Roberts, then chief medical officer to the Post Office, to tackle the problem of chronic bronchitis in postmen, and we discussed the matter with Prof R Christie.

Four years later, when I joined the bronchitis research team of Dr N C Oswald, I decided to leave aside the postmen for the time being, because they form a selected group in which very special factors create problems which do not exist elsewhere. To counterbalance those special circumstances by a control group of non-bronchitic postmen can be fallacious, as is known to doctors who had a large number of postmen under their personal care before the introduction of the National Health Service. Two of those factors I am not at liberty to discuss at present A third—the influence of polluted air on respiratory morbidity—appears certainly correct in that "the acute effects of foggy conditions emerge from the coincidence of onset of bronchitis attacks with thick fog rather than of cold and humidity", but Dr Reid's conclusion that in the London area the "month-to-month changes in incidence [of bronchitis in postmen] are more closely related to changing fog frequency and thus, in a built-up area such as London, to the associated air pollution", I am not willing to concede so simply, because there is a possible source of error in the case of the London postmen. The honest admission by Dr. Reid and Dr Fairbairn ("Although the role of atmospheric pollution in precipitating and aggravating bronchitis may thus be evident, the personal factors involved are still obscure") is caused by the lack of intimate knowledge of how London postmen live and work, which could be acquired before 1948 Such knowledge was the reason why I decided to regard bronchitis in London postmen as a rather special problem, and set it aside for the time being

In my report of January, 1957 (based on the observation of 502 patients clinically and of their sickness-absence records), I came to the conclusion that the sickness record in earlier adult life may have not only *some* (Reid) but also exceptional value in identifying men more likely to develop disabling respiratory disease. In addition, I singled out a group of people who had had a definite history of bronchitis in early childhood, which later seemed to clear up, but recurred after the age of forty Those could be patients whose bronchi had undergone early morbid anatomical changes, as described by Dr Lynne Reid.[1]

---

[1] Reid, L. *Lancet*, 195[illegible], i, 275

Finally, Dr Reid's statement, "   since no smoking histories either of 'bronchitics' or controls could be obtained, the role of smoking as a contributory cause of regional and other differences in the natural history of bronchitis cannot be assessed", appears surprising, because in our paper on the effect of cigarette smoking on chronic bronchitis,[2] it was to Dr Reid that Dr Oswald and I gave thanks for assistance in interpreting the statistical aspects The population concerned was 5844 Civil Service clerical workers in the London area, and the conclusion reached was that "the proportion of clerical workers having minor respiratory symptoms and bronchitis was consistently higher in smokers than in non-smokers" Another finding discussed was the strikingly similar prevalence of bronchitis in males and females

London, S W 1 V C MEDVEI

THE BURNING-FEET SYNDROME

SIR,—I read with great interest your annotation of March 8 and Dr Gopalan's letter of April 12 I have observed the burning-feet syndrome in patients with liver disease—subacute viral hepatitis or portal cirrhosis Some of these patients had other signs of vitamin deficiency, such as cheilosis and/or red tongue In none of them was alcohol a contributing factor

The case-histories and morphological findings have been published in detail elsewhere [3] Two patients died from hepatic failure and the spinal cord and peripheral nerves were investigated No pathological changes were seen in the cord Severe changes were found in the small nutrient arteries of the sciatic nerve, however, with thickening of the endothelial layer and narrowing of the lumen, destruction of muscle, cellular infiltration of the adventitia, and granuloma-like formations of adventitial cells (fig 1) The degenerative lesions of the nerve with loss of the medullary sheaths were thought to be secondary to impaired nutrition (fig 2)

These findings seem to confirm Page's opinion [4] that this condition might be due to vascular changes, as suggested by Kinoshita's observations in Japan

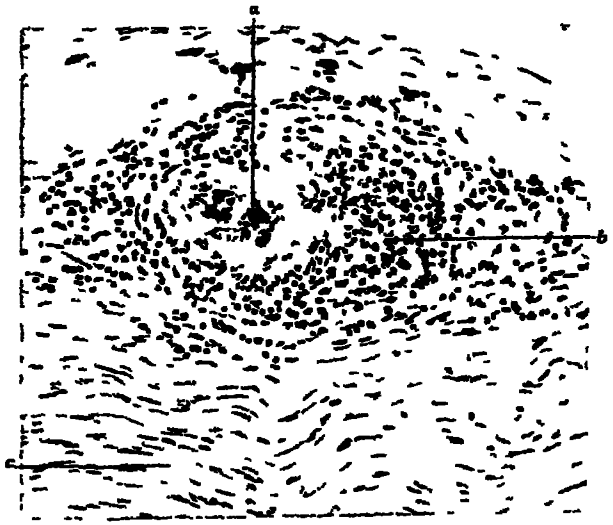

Fig 1—Nutrient artery of sciatic nerve (*a*) lumen nearly obliterated, (*b*) the muscle tissue is destroyed, with cellular infiltration and granuloma-like proliferation of adventitia cells, (*c*) nerve (×80)

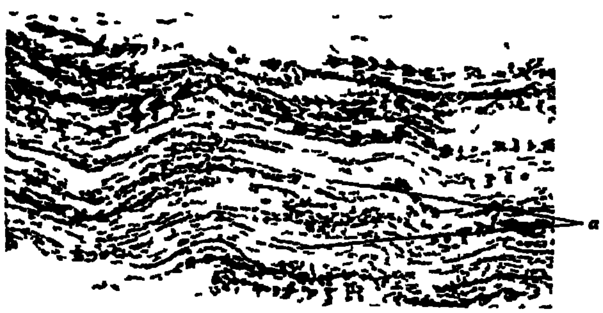

Fig 2—Loss of the medullary sheath, only some normal sheaths remain (*a*) empty endoneural sheaths (×80)

As Dr Gopalan rightly says, the syndrome has several causes It is obvious that once the peripheral nerve is impaired by obliteration of the nutrient arteries vitamin therapy will fail, it was never successful in our cases This may partly explain the therapeutic failure in the series of Bibile et al to which you refer On the other hand, the use of a vasodilator drug, such as nicotinic acid, may be followed by a transient improvement

TREATMENT OF UNDULANT FEVER

SIR,—I have read Dr Lehmann's letter (Feb 8) with great interest, and I wish to make certain points clear

My experience in undulant fever can be divided into three well-defined periods

(1) *1925–42* I saw 637 cases, of which 272 had no special treatment The rest were treated with amidopyrine, neoarsphenamine, gold salts, a formolised extract of *Brucella melitensis* ('Formomelitine'), vaccines and auto-vaccines, or sulphonamides This group is interesting because it provides important data average length of illness, six months, relapses, generally within a month (with no fever) but sometimes after two months, mortality about 6%, incidence of arthritis 8% and of orchitis 12%

(2) 1942–57 I treated 117 patients with antibiotics The figures for most of them are shown in the accompanying table

—	No of cases	Relapses (%)	Cured (%)	Improved (%)	Died (%)	% discharged (month of illness)				
						1st	2nd	3rd	4th	5th
Aureomycin (10–35 g)	77	66	22	71	6	70	13	6	3	1
Chloramphenicol	19	58	37	63	0	63	21	11	5	1
Oxytetracycline plus streptomycin	9	11	56	44	0	78	22	—	—	—

By "cure" I mean disappearance of all symptoms, and by "improvement" persistence of one or more symptoms The results with aureomycin (chlortetracycline) and chloramphenicol were similar, but defervescence was quicker with aureomycin I have treated 3 patients with oxytetracycline alone, 2 with streptomycin alone, and 7 with combinations of various antibiotics, without improving on the figures for aureomycin My best results were with the combination of streptomycin and oxytetracycline, but in none of these cases, except where patients return to hospital, have we known their ultimate condition

Since my article of Jan 25 I have had further experience with 'Cathomycin' (novobiocin), and the results continue to be as I reported

It is most important, however, to know the ultimate fate of the patients who have had novobiocin, and I wrote to the doctors in the villages where patients discharged between fifteen and three months ago are living Of the 36 patients about whom we asked, in 32 there has been no relapse

---

2 Oswald, N C, Medvei, V C *ibid* 1955, ii, 843
3 Martini, G A., Kalm, H *Dtsch Z Nervenheilk*, 1951, 166, 17
4 Page, J A *Brit med J* 1946, ii, 260

Two weeks after he went home, 1 of the remaining 4 had a slight febrile illness which recovered at home with no drugs or antibiotics and which was not bacteriologically studied. Another was sent to hospital a month after he was discharged, as he suffered a relapse that was bacteriologically verified. This was again treated with novobiocin with results as satisfactory as in any other febrile patient treated for the first time. He has had no more relapses. The 2 other patients were not known to the doctors to whom we wrote.

Patients who receive no treatment relapse after a period of one or two months, a fact which makes these findings more impressive, as I hope Professor Debono (March 15) will agree.

As to the appearance of rashes, we realise that there can be racial differences in sensitivity to cutaneous exanthems. Their consequences, however, can be greatly mitigated if they are treated adequately. Fortunately, we have had to stop very few treatments, and, even with rashes, we have been able to cure the patient.

It is now wise to wait for the results from a greater number of cases, and I assure Dr Debono that when we have this information we shall record the full details. Meanwhile, our daily increasing experience in acute and chronic cases is strengthening the impression I stated in my article—namely, that novobiocin is the specific drug for the treatment of brucellosis.

Madrid. J. TORRES GOST

"THESE DYING DISEASES"

SIR,—Dr Morrison (May 17) has evidently not understood my letter of April 19, nowhere in that letter do I advocate abolition of the venereal-diseases clinics and dispersion of patients elsewhere. My object was to try and have ready a scheme for the care of these patients if and when the supply of venereologists becomes insufficient for the staffing of the service as at present constituted. It is common knowledge that difficulties already exist in the more remote parts of the country, and one has only to look down the names of the members of the staff of the hospitals in England and Wales to realise that many venereologists have already to cover enormous areas.

The questions raised by Colonel Harrison, Dr Catterall (May 3), Dr Morrison (May 17), Dr Willcox (May 24), and Dr Knight (May 31) are those which need answering constructively. I entirely agree with Colonel Harrison that the present system for treatment of venereal disease can, with very few exceptions, be carried out only by venereologists. Dr Morrison should know that it is because I refused to run the V.D. department in Sheffield on my return from the late war that there is now a consultant venereologist in Sheffield. As a non-venereologist I realised that I was incapable of running an efficient V.D. department on the existing system. It is from this knowledge of the difficulty of working the present system by non-venereologists that I feel that some scheme should be ready for implementation in areas in which posts falling vacant cannot be filled.

If my fears are groundless and recruits of consultant calibre are attracted to venereology, so much the better, and the thought of a helicoptering venereologist serving an enormous number of clinics will be an idle speculation. I do not suggest that the scheme which I put forward is necessarily the best, but at least it would be workable on the existing National Health Service.

Oxford. H. R. VICKERS

TREATMENT OF ASTHMA AND HAYFEVER BY HYPNOSIS

SIR,—Dr Mason and Dr Black (May 24) are concerned at what they consider to be a misinterpretation by me of the method of skin testing employed in their investigation.

They claim that their method of multiple-pressure testing was not a "prick test at all", yet they give an admirable description of the best method of performing a prick test—namely, the introduction of the sharp end of a needle through a drop of extract into the skin, with minimal trauma and yet capable of exciting a reaction. This is the method I employ and advocate for diagnostic testing and which I and others call a prick test. One such prick can and frequently does excite strong reactions, and it is no exaggeration to describe their procedure of ten such pricks on one site as vigorous testing, from which one would expect greater local and systemic after-effects.

I suggested for consideration local "desensitisation" for the loss of sensitivity on the much-tested left arm, and the peripheral vascular effects of hypnosis for the absence of a reaction on the left leg after direct hypnotic suggestion. Discussion of these suggestions would have been more satisfactory if the authors had conducted controlled investigations into local "desensitisation", and into the effects of hypnosis per se and of direct hypnotic suggestion on reactions to allergic and non-specific wealing agents. One would have thought such a control study a basic prerequisite for Dr Mason and Dr Black's study, especially since a single case was involved.

They state that they will be publishing shortly a report on the effects of hypnosis on the tuberculin reaction. There is evidence that peripheral vascular responses can modify tuberculin reactions strikingly.[1] Since such modifications may be paradoxical and complex, depending upon whether antigen, antibody, or inflammatory responses are most involved, care is required in interpreting the results. It is not unexpected that hypnosis may, if only by altering peripheral vascular responses, modify tuberculin reactions, and the examination of skin-biopsy sections from test sites which fail to react under hypnosis may help to provide useful information.

London, W.1. J. PEPYS

PULMONARY MONILIASIS TREATED WITH NYSTATIN AEROSOL

SIR,—Dr McKendrick and Dr Medlock (March 22) report a case of pulmonary moniliasis treated with nystatin aerosol. We have successfully treated a case of pulmonary aspergillosis with inhalation of nystatin.

A farmer, aged 56, was admitted to our clinic in October, 1955, he had had stabbing chest pain for several weeks, and frequent cough with much greenish-grey sputum, he felt weak, had lost weight, and had slightly raised temperatures. Physical examination revealed only a moderate emphysema. The erythrocyte-sedimentation rate (E.S.R.) was 58 mm. in 1 hour. A radiograph revealed calcified residues of a specific apical process and a faint shadow of one fingerbreadth near the upper pole of the left hilum. No tubercle bacilli in the sputum. 2 months later the patient reappeared with complaints of further weight loss, stronger cough and more sputum, stabbing chest pain, and temperature of 38°C for a week. The physical signs and E.S.R. were unchanged. On the radiograph of the chest a three-fingerbreadth shadow appeared in the right mid-zone of indefinite outline and varying density. After treatment with penicillin and streptomycin the temperature fell, but not to normal, the E.S.R. increased to 87 mm., and a chest radiograph revealed an increase of the shadows on both sides. In sputum and bronchoscopic wash-fluid fragments of hyphæ were seen on the direct film and the culture produced

---

[1] Pepys, J. *Amer. Rev. Tuberc.* 1955, 71, 49.

Aspergillus fumigatus Treatment with nystatin ('Mycostatin') was started, with daily oral doses of 1 million units The general condition improved somewhat, but the E S R and X-ray appearance did not change After 6 weeks of oral treatment the X-ray shadows were moderately increased, and 2 weeks later a new spotted shadow appeared in the left lower zone The leucocyte-count increased to 12,000–14,000 per c mm In June, 1956, we injected through the bronchoscope 250,000 units of nystatin, in 0 9% saline suspension, into the main bronchi The patient had chills and fever for 3 days, his general condition deteriorated, and the cough increased When the fever subsided we continued to give nystatin by mouth and introduced at the same time treatment by aerosol, thrice daily, beginning with 30,000 units and increasing the dose up to 500,000 units This treatment was given, with interruptions of 1–2 days, for 4 weeks, the general condition of the patient improved, his weight increased, cough and sputum decreased, the temperature became generally normal, and the E S R fell to 29 mm X-ray examination showed a substantial regression of the intensity and extent of the shadows No aspergillus could be grown from the sputum or from the bronchoscopic wash-fluid

After a further 6 months of nystatin treatment the radiograph became clear We attribute the success of the treatment chiefly to the application of nystatin by aerosol Since 1956 the patient has remained in good health and continues to work in his profession

VISITING MENTAL HOSPITALS

SIR,—Although the comments of both Miss McClellan and Miss Clarke (*May 31*) are not only true but admirable, they are in no respect a reply to my letter, and, since both appear to have overlooked the only point raised, they unfortunately add nothing towards a solution of this problem My remark concerning visits by *parties* of guildswomen was incidental

It is, therefore, not without significance that both your correspondents lay stress on visits by women's organisations, for this leaves the issue untouched The point is that although *individual persons* are permitted and welcomed to visit our general hospitals for philanthropic purposes, a similar request to visit a mental hospital is invariably turned down

I have written to twenty mental hospitals seeking such permission, and as these twenty applications have met with flat refusals, perhaps Miss McClellan would care to fulfil her desire, and add not only to her happiness but to mine, by introducing me to only *one* medical superintendent in the British Isles who will permit such visits

Edzell, Angus

H G WOODLEY

AN ORAL CONTRACEPTIVE

SIR,—You report (April 19, p 844) a lecture by Dr Gregory Pincus on Fertility Control with Oral Medication Dr Pincus describes experiments made "first in volunteers then in patients in a mental hospital" to assess the ovulation-inhibiting effect of certain compounds, and refers to the indices of ovulation used which included vaginal smears and endometrial biopsies

In 1957 you reported two other American sets of experiments in which mental-hospital patients had been used as guineapigs As I said in my protest[1] about one of these experiments, "this use as guineapigs of chronic psychotic patients who are not able to give or withhold valid permission for experiments in physiological research of this type must be as repugnant to many of your readers as it is to me"

Hawkhead Hospital,
Glasgow

JAMES MILNE

⁂ We have shown Dr Milne's letter to Dr Pincus and his reply follows —ED L

SIR,—Dr Milne's remarks do not seem to me to be particularly applicable to the experiments which we have conducted We reported on the administration of progesterone by mouth to a group of psychotic women and on the administration of a new oral progestin, 17α-ethinyl estra-(5, 10)-eneolone, to a comparable group This experiment was conducted in view of the reported efficacy of progesterone given by injection to women with certain types of psychosis Concomitant observations were made on the physiological effects and the psychiatric state of the patients The physiological observations made would have been impossible without the active and willing cooperation of the patients Furthermore, permission to undertake these observations was obtained from the responsible relatives or guardians of the women patients involved

GREGORY PINCUS

TIME AND THE NERVOUS SYSTEM

SIR,—The definition of a clock given under my name by Dr Gooddy, in your issue of May 31, will be unintelligible to your readers if it is not supplemented by an explanation of what is meant by an A-line If I may be permitted to remedy this deficiency I would explain that an A-line is any unbranched succession of single events, with a first and last term, and such that the first term adjoins the second, the second the third, and so on to the last term One event adjoins another if the end of the former is identical with the beginning of the latter An event is anything which has a beginning and an end in time

According to the definition given by Dr Gooddy a succession of twinges of toothache alternating regularly with smells of onions, all in the experience of one and the same person, would constitute a clock, provided the durations of the twinges and of the smells were all identical But this would be a purely personal clock The clock in the general sense here defined must be distinguished from the pieces of machinery which stand in our halls or on our mantelpieces and are also called clocks These latter are clocks in the above sense *only* when they are *going*

Middlesex Hospital Medical School,

Obituary

ALFRED EDWARD WEBB-JOHNSON

BARON WEBB-JOHNSON OF STOKE-ON-TRENT

Bt, G C V O, C B E, D S O, M B Manc, LL D, F R C S

Alfred Webb-Johnson transformed, successively, the Middlesex Hospital Medical School, the Middlesex Hospital itself, and the Royal College of Surgeons of England He was shrewd in knowing how an institution should develop so as to fulfil its purpose better, he set himself to see that what was needed was done, and he got help and money for his schemes because he could communicate his enthusiasm yet at the same time inspire confidence by his sagacity and sense Transformer rather than reformer, he was not an original thinker, and his talents were no greater than those of many other surgeons But he was an idealist who pursued his ideals with exceptional resolution and exceptional success, and if these ideals were limited they were also important Much of what he built will long stand visible in London, but his greatest service—less tangible—was to reinvigorate his college, which he and his associates since the war have made into a major centre of professional life both for this country and for the Commonwealth

Son of Julia Webb and Samuel Johnson, M D of Queen's University, he was born in 1880 at Stoke-on-Trent, where his father practised and was medical officer of health He did well at Manchester University, winning surgical prizes, and was surgical registrar at the Manchester Royal Infirmary In London he became resident medical officer at the Middlesex Hospital, and in 1911 was elected to the staff He was already in charge of the hospital company of the University of London Officers Training Corps, and in the 1914-18 war he showed his administrative capacity both in command of a hospital and as a consulting surgeon, B E F Returning to civil life as D S O, C B E, and honorary colonel, he entered on six eventful years as dean of his medical school

He was keenly interested in science in general—not merely science as applied to medicine—and he saw that unless the primary departments in a medical school are research departments, in the true sense of the term, medical education must sink to the level of coaching At the Middlesex, by his own efforts, he established a group of professional departments that can hold their own with any university in the country

"One of his particular traits," writes E C D, "was his love of attempting the impossible It was only necessary for some august body to say that such and such a person could not be appointed to a certain position, for various reasons, to stimulate Webb-Johnson to try his strength and come to grips with the authorities This led him into many strange actions, and perhaps the strangest of all—and the one he was fond of referring to—was when he obtained a full professorship in the London University for one of his proteges at the age of 25

"To the end of his days he retained a great interest in young people, and he never lost an opportunity to give them a chance of showing what they were worth Once he had selected a man, he would back him to the fullest extent of his power"

In 1923 he made a tour of hospitals and medical schools in the United States and Canada, and when, two years later, the fabric of the old Middlesex Hospital was found to be unsafe, he was made chairman of the rebuilding committee The slogan "The Middlesex Hospital is Falling Down" appealed to the public, and Webb-Johnson appealed to the men of means whose great benefactions allowed the board to put up the present hospital at a cost of £1¼ million Having done so, the board paid him an unprecedented compliment by naming a ward after him while he could still have his patients in it

His specialty was urology, and he started the urological department at the Middlesex, but he was prepared to undertake any problem in general surgery E W R, his student, his registrar, and later his colleague, writes

"As a teacher he excelled in imparting the fundamentals of surgery, and his ward rounds were popular as well for their intrinsic value to the student as for their amusing comments on the affairs of the day As a chief, he was most generous to his assistants, giving them many chances to practise for themselves what they had learnt from his example His criticisms, though apparently spoken in jest, were always to the point and intended to be taken in earnest As an operator he was quick and dexterous, and in dealing with an emergency he followed the motto of 'quickly in and quicker out' As a doctor he was beloved by all his patients for his unbounded sympathy, ready wit, and unfailing good humour He will be remembered with affectionate loyalty by all who had the privilege of working with and for him"

In 1936 he was knighted Three years later he delivered the Syme oration of the Royal Australasian College of Surgeons, taking them a message from Queen Mary, to whom he was now surgeon-in-ordinary In July, 1941, two months after the partial destruction of the English college by bombs, he assumed its presidency, which he was to hold until 1949—longer than any president before him

Under Webb-Johnson's leadership, the college's disaster became opportunity, and restoration became reconstruction Once again he showed his power to fire others with his faith, and among his vicarious memorials none perhaps expresses that faith so well as the Nuffield residential college of surgery, which opened with its first 25 students just before he left office Other donors, meanwhile, had been led to equip laboratories and endow professorships and departments, by which the college, as a centre of postgraduate education, has enlarged out of knowledge What had been "little more than a rendezvous for examiners and surgical aspirants" became a living organism "alive with youth and enterprise and ambition", in which seniors and juniors meet for informal as well as formal instruction Nor are they surgeons only, for by the end of Webb-Johnson's presidency many smaller bodies were in orbit round the surgical planet Perhaps because this seemed likely to happen to them too, he did not succeed in attracting to Lincoln's Inn Fields the sister colleges which might have formed, with his, the Academy of Medicine which he thought overdue But much integration was nevertheless achieved H S S recalls his own long discussions with the President on how the separating parts of surgery could be kept under one roof

> “ I had suggested the formation of faculties, and he asked me to put down my ideas on paper So one evening in 1941 I went round to take him a draft and we discussed it for a couple of hours during one of the heaviest air-raids of the war! The result was the formation of the first two faculties—Dentistry and Anaesthesia They have been a great success and several similar groups have enabled the college to hold together sections which would have otherwise parted
>
> “ Equally important was the co-option to the council of representatives of groups which could not otherwise hope for election—general practice, ophthalmology, obstetrics, dentistry, anaesthesia, and laryngology, if my memory serves me right It was a bold move and a great success ”

Similarly, support and encouragement was given to specialist associations, by providing them, in Lincoln's Inn Fields, with a secretariat and offices for their journals Since 1947, moreover, the college too has had a monthly journal of its own, the *Annals*, which is a link between its far-flung fellows

Webb-Johnson had received a baronetcy in 1945 and he was raised to the peerage in 1948 But, though he had used moderating influence in the crisis over the introduction of the National Health Service, he developed no great taste for debating medicopolitical issues in the House of Lords, preferring always the more direct task In 1950 he became president of the Royal Society of Medicine, then in the throes of adding to its building, and, as usual, he was able to gain the financial support it needed Other duties which he gladly laid on himself were those of president of the Royal Medical Benevolent Fund, and hospitaller of the Order of St John of Jerusalem The many honours which also came to him included the fellowship of the Australasian, American, Edinburgh, and Irish colleges of surgeons, honorary degrees from Liverpool and Toronto, and the highest possible marks of esteem from his own college But, though he enjoyed such recognition—having always given the world at least its due—he avoided pomp, just as he had preferred so often to do his work unobtrusively Like all forceful men, he could be intimidating, but the years emphasised, instead of diminishing, his humanity, and a great many people who knew him will remember him less for his contribution to the surgery of coming generations than for the unexpected fraternity of some casual greeting, for his habit of gentle badinage, or for one of those friendly notes, in his strong and legible script, which were “ Webb-J ’s ” and his alone

Alfred Webb-Johnson married, in 1911, Cecilia Flora, daughter of Douglas Gordon MacRae Lady Webb-Johnson is a member of the court of patrons of the college, as well as its honorary medallist Her MacRae-Webb-Johnson gift to the Hunterian trustees commemorates both her father and her husband

---

When I joined the council of the Royal College of Surgeons in July, 1940, Alfred Webb-Johnson was admitted on the same day for his second eight-year period of service At the end of the council meeting he was elected a vice-president, and a year later he reached the presidential chair, although on the council at that time there were several elder statesmen who had served for longer periods It seemed clear that in the crisis which then confronted the college, Webb-Johnson was the “ man of the moment ” During the eight years of his presidency, with others I witnessed his masterly handling of the sequence of events, and was inspired by his vision of what a restored and extended college would mean one day to the prestige of British surgical science It was an unforgettable experience, which was to sustain me when five years later I was unexpectedly called upon to occupy what Webb-Johnson had called the Surgical Woolsack But that was not my first glimpse of this remarkable man in action, for many years before, as surgical registrar at the Manchester Royal Infirmary, he had been one of my teachers At that stage in his career Webb-Johnson was deeply influenced by the intellectual distinction of Mr (afterwards Sir) William Thorburn, whose house-surgeon I was destined to become It was through our common devotion to our brilliant chief that a close bond of friendship was forged between us

Although, after his migration to the Middlesex Hospital, Webb-Johnson became in outward appearance and in his way of life the very model of a London surgeon, throughout his long and distinguished career his attachment to his alma mater remained unshaken As an undergraduate he had been a product of a vintage period which gave to the Manchester medical school a small group of men distinguished later as consultants and teachers—among them Sir William Fletcher Shaw, afterwards president of the Royal College of Obstetricians and Gynæcologists In the company of such men of high ability—and (it is recorded) of high spirits—Webb-Johnson spent his first resident appointment as house-surgeon at the old Manchester Royal Infirmary in Piccadilly It was an experience which provided him with a wealth of anecdotes One which he recounted again and again was of the appearance at the infirmary on a Sunday afternoon of a mysterious stranger, who after enjoying the conversation and hospitality of the residents' common-room, left to take an evening train to London This was none other than Sir William Osler, who later revealed his identity by sending a photograph of himself with an inscription referring to the convivial habits of the residents of the Manchester Royal Infirmary

Until the outbreak of the second world war, Webb-Johnson paid regular visits to Manchester and was an outstanding figure at the reunions of the Manchester Royal Infirmary Old Residents' Club Thus he became known to successive generations of Manchester graduates, who came to feel that in London there was a friend and counsellor to whom they could turn for help and advice Webb-Johnson's undergraduate education and earlier postgraduate training in surgery in a medical school which was an integral part of a civic university—indeed in his day the medical students of Manchester played a dominant role in the social, cultural, and sporting life of Owen's College—gave him a breadth of outlook which became increasingly manifest when he was elected to control the destiny of the Royal College of Surgeons He saw the future of the three Royal Colleges acting in concert—better still, coming together as physical neighbours in the great square of Lincoln's Inn Fields—as an independent and parallel power vis-a-vis the universities in the world of medical education and research This was the essence of his conception of the shape of things to come, and to the Royal College of Surgeons at least he has bequeathed a supreme heritage

H P

In face of his many achievements it is easy to forget that Alfred “ Webb-J ” was an excellent and skilful surgeon, and that the pathway on which he placed his early footsteps, and which was to lead steadily upwards, was indeed a surgical one

I can still remember watching him about half a century ago when he performed his very first operation at Middlesex Hospital and envying the skilful, rapid, and in his hands almost bloodless manner in which he completed a “ Whitehead hæmorrhoidectomy ” He had of course both watched and known Whitehead in his Manchester days

Although in every sense a general surgeon, from the first Webb-Johnson had a penchant towards urology he was one of the first to explore the possibilities of pyelography, and of the purely technical papers which he wrote not a few dealt with urological problems, notably an address to the Manchester Surgical Society on uretero-vaginal fistula which distressing condition he had met 23 times in 23 years

Like many surgeons of olden days as well as modern times his first great experience of surgery was in the service of Mars, and as commanding officer of the world-famous 14 General Hospital at Wimereux in the 1914–18 war, and subsequently as one of the consulting surgeons to the Boulogne base, he was immersed in traumatic surgery In addition he had the opportunity to study first hand and to operate on many patients suffering from surgical complications of typhoid and paratyphoid fevers, and his experience was published first in *The Lancet* (Dec 1, 1917) and subsequently in book form

"Webb-J" was not one of those who essayed novel and daring methods of treatment, but he had plenty of courage when occasion demanded, as when he successfully removed a spleen in an infant two days old for some blood dyscrasia Probably his manifold other interests and the demands on his time did not permit the anxious sleepless nights inseparable from "progressive" surgery The tragedies which he had witnessed in France in the 1914–18 war in the inception of blood-transfusion made an impression on him which remained till the end of his life, and in his surgery he never employed transfusion recklessly and wantonly He was a great friend of Bland-Sutton, from whom he learned the importance of time in surgery

In his early years the influence of Thorburn and the other distinguished neurological workers in Manchester gave him an interest in neurological anatomy, and his illustrations are still to be found in books on anatomy—e g, Treves' *Surgical Applied Anatomy* depicting the fundamentally segmental distribution of the anterior primary divisions of the spinal nerves in the limbs

If the opportunity for service be one of God's greatest gifts to man, "Webb-J" used that gift to the full, but although his skill, the "good doctor" in him, the encouragement that came from his lips, the ready joke, the smile were at the service of each one of his patients, it was rather to suffering humanity as a whole, and to those who minister to alleviate and cure, that he dedicated his great gifts of vision and leadership, and his untiring effort to achieve his object in a worthy cause

G G-T

JAMES WOOD-WILSON

T D, M.D Glasg, D.P H.

Dr Wood-Wilson, county medical officer and principal school medical officer for the West Riding of Yorkshire, died at Wakefield on May 23 after an illness of only a few hours He was 54 years of age

He graduated M B from the University of Glasgow in 1927, and took the D P H three years later After two years as an assistant medical officer at Robroyston Sanatorium, near Glasgow, he joined the staff of the West Riding public-health department in 1932 as an assistant tuberculosis officer He took the M.D the following year, and in 1936 he was appointed an assistant administrative county medical officer with charge of the school and maternity and child-welfare services He had always been an enthusiastic Territorial and in 1939 he held the rank of major in the R.A M C He was at once called up to serve as regimental officer to the 4th battalion of the K O Y L I In 1941 he was released at the request of the West Riding council to take up the post of deputy to the county medical officer He held this appointment till he himself became county medical officer in 1954

Dr Wood-Wilson had much to do with the planning and development of the West Riding scheme for the preventive medical services, and the monthly meetings of the divisional medical officers took place under his chairmanship In 1954 he was largely responsible for the formation of the standing subcommittee on cooperation between medical practitioners and medical officers of the West Riding and he was lately elected chairman of this subcommittee He regularly attended liaison meetings between medical officers of health and the Leeds and Sheffield Regional Hospital Boards

In 1948 he was the captain of the Wakefield golf club and he was often to be found on the golf course in his leisure moments On the reconstitution of the Territorial Army he again became the medical officer to the 4th Battalion K O Y L I, and was awarded the Territorial Decoration and clasp He is survived by his widow, son, and married daughter

A colleague writes Dr Wood-Wilson was an eminent and well-loved member of the public-health service A man of a wide variety of interests, and possessing a very keen intellect, he brought to his work both abundant kindness and sympathy He was tolerant and understanding, with the result that a friendly relationship was built up with all those with whom he came into contact. Of great good humour and limitless patience, he possessed the happy ability of being able to see the other person's point of view His death is mourned by the entire staff in the West Riding health department.

DUNCAN LESLIE FOX

M B Manc, D.P M

Dr Duncan Fox, who had lately been appointed county psychiatrist in Staffordshire, died on May 27 at the age of 33

A brilliant student, he graduated M.B with honours from the University of Manchester in 1948 After holding house-appointments in Manchester at the Royal Infirmary and Crumpsall Hospital he served in the Royal Air Force. In 1954 he took the D P M., and he held posts in psychiatry at Prestwich Hospital, with the Government of Saskatchewan, and in the Manchester region before he took up his present appointment. He leaves a wife and young daughter

N B writes

The ability that made Duncan Fox an outstanding student also characterised his postgraduate career before the onset of his illness There was nothing about his work that was not first-rate and that did not bear the stamp of a fine and exceptional intelligence. Allied to this he had a warm and generous personality that made him beloved by his patients He was a clinician above all else, and in the somewhat dismal world of the mental hospitals in which he worked new entrants to the specialty found his work an inspiration and to him they owe an incalculable debt. He will be missed by many, not least by the countless patients for whom he did so much in those brief years

Appointments

Bloom, H. J G, M.D Lond., M.R.C.P, F.F.R., D.M.R.T consultant radiotherapist, department of radiotherapy, Royal Marsden Hospital, London

Henderson, Dinah C. M, M.D Edin., D M.R.D senior registrar in radiology, The Hospital for Sick Children, Great Ormond Street, and Royal Free Hospital, London

Heron, W C., M.B Belf, D.M.R.D assistant radiologist, Leicester Royal Infirmary and Leicester General Hospital

Hird, Gordon, M.B Aberd, D.P.H M O H. and port M.O, Boston, and assistant county M.O, Holland (Lincs)

Tonge, W L., M.D Manc., D.P.M part-time consultant psychiatrist, Royal Infirmary and Whiteley Wood Clinic, Sheffield.

Birmingham Regional Hospital Board

Bevan, P G, M.B Birm, F.R.C.S consultan surgeon, Birmingham (Dudley Road) group of hospitals

Boyle, J B F, M R.C.S F F.A.R.C.S., D.A. part-time consultant anæsthetist, Wolverhampton group of hospitals

Dencer, Derrick F.R.C.S.E. part-time consultant plastic surgeon, Coventry, Dudley and Stourbridge groups of hospitals.

Hennessy, J D, M.CH N U I, F.R.C.S.E. part-time consultant surgeon, West Bromwich group of hospitals

McDowell, R. F C., M.D Belf., D.M.R.D part-time consultant radiologist, Stafford group of hospitals

Newsholme, G A., M.D Cantab, M.R.C.P, D.M.R.T consultant radiotherapist, United Birmingham Hospitals and Birmingham (Dudley Road) group of hospitals.

Notes and News

PUBLIC-HEALTH DOCTORS' PAY CLAIM

THE Industrial Court has found that a claim for a 5% increase in the salaries of public-health medical officers has not been established The claim covered 2500 doctors and would have cost about £200,000 a year The court said that the doctors must be considered part of the local-authority hierarchy, and, as a claim for local-authority officers from other professions was under consideration, it would " not be appropriate for the salaries of medical officers to be dealt with piecemeal and in isolation while that general claim was outstanding " The award is without prejudice to any claim which the medical officers may put forward when the general claim is settled

WORLD HEALTH ASSEMBLY

THE tenth anniversary commemorative session of the World Health Organisation opened at Minneapolis, Minnesota, on May 26, when Dr Sabih Hassan Al-Wahbi (Iraq), the president, said that W H O 's main task today was to help governments to strengthen their own health services Delegates reviewing progress in their own countries included Dr A da Silva Travassos, who said that malaria had been almost eliminated from continental Portugal, and a regional agreement was being negotiated with Spain for consolidating eradication throughout the Iberian peninsula Pyo Wook Han, Korean Minister in Washington, said that, thanks to international cooperation, there had been only seven cases of smallpox in his country in 1957, compared with more than 43,000 in 1951, 187 cases of typhus, compared with 32,000, and 657 cases of typhoid fever, compared with 81,000 Dr H Kraus (Yugoslavia) predicted that countries which were not now members would soon join W H O , because health problems could be completely solved only on the international level Dr Brock Chisholm (Canada), first director-general of W H O , said that the Organisation had come to be widely recognised for efficiency This was due to the unique character of the Executive Board, whose 18 members act purely as health experts and not as representatives of governments Any attempt to convert the Executive Board into a political body would threaten the future of the Organisation Dr E A Aujaleu (France) said that the various W H O meetings over the past ten years, though not entirely immune to political problems, had attained a remarkable degree of harmony International cooperation would be promoted if people stopped dividing the world into developed and under-developed countries Dr Karl Evang (Norway) said that, owing to lack of funds, W H O was unable to utilise fully the technical knowledge at its disposal Ten years ago the Organisation had hoped to start with a budget of $25 million, but this minimum had not yet been achieved

LONDON SCHOOL OF DENTAL SURGERY

WITH the post-war increase of dental students and the growing needs of research, this school has been finding its share of the buildings of the Royal Dental Hospital on the south side of Leicester Square more and more cramped When Ciro's Club was closed and its premises in Orange Street, immediately behind the hospital, fell vacant, the school authorities acquired the building and received a grant from the University Grants Committee for its purchase, reconstruction, and equipment On June 3 the Queen opened the new extension, which will provide a lecture theatre for 70 students, laboratories, offices, a students' common room, library, and animal rooms

The conversion of a night club into a dental school presented the architect, Mr Douglas Nightingale, F R I B A , with unusual problems To gain more space the main restaurant was floored over at balcony level, and an additional floor erected on the roof Light-weight materials were used so that the building could carry this extra load without expensive alterations In the basement party and external walls were underpinned, and a lecture theatre with tiered seating was then provided by excavation without having to encroach on two floors The theatre has a large projection room, with facilities for storing slides, and a removable bench for demonstrations Operations can be televised while in progress and projected on to a screen in the lecture hall, which also has projection equipment for visual lectures, with facilities for projecting sound on film and with direct intercommunication between the lecturer and projectionist

As the new extension is geographically separate from the hospital a special staff-locating system has been provided and a loudspeaker system with master stations installed Heating and domestic hot water are provided by the hospital's boilers, and wayleave was obtained to bring the pipes through a building which stands between the hospital and the extension As a final example of thrifty improvisation, the spring dance-floor of Ciro's has been resurfaced and now finds a place in the students' common room

CENTRAL HEALTH SERVICES COUNCIL

THE Minister of Health has appointed or reappointed the following doctors to the council and standing advisory committees for the period ending March 31, 1961 New appointments are indicated by an asterisk

Central Health Services Council

Lord Cohen of Birkenhead (chairman), Sir Stanford Cade, Dr Annis Gillie, Prof A J Lewis, Dr Wilfrid Sheldon

Standing Advisory Committees

Medical—*Dr G C Kelly, *Dr Stanley Thomas, Lord Cohen, Sir Stanford Cade, Dr Gillie, Professor Lewis, Dr Sheldon

Dental—Prof M A Rushton, Prof F C Wilkinson

Pharmaceutical—*Dr A M G Campbell

Ophthalmic—*Dr Dorothy Campbell, Mr O G Morgan

Mental Health—*Dr J A Scott, *Dr D H H Thomas, Professor Lewis

Cancer and Radiotherapy—*Mr R D Owen, *Prof D W Smithers, Sir Stanford Cade, Sir Ernest Rock Carling, Lord Cohen, Sir Charles Dodds

Maternity and Midwifery—Prof W C W Nixon

Tuberculosis—Dr P M D'Arcy Hart, Dr Peter Kerley

THE EDUCATION OF THE SCIENTIST

AT the annual meeting of the Manchester Medical Society on May 7, Sir ERIC JAMES, high master of Manchester Grammar School, said that, as regards the specialist education of the scientist, the main point of controversy concerns the degree of specialisation Here there is much confusion, because it is not yet realised that science is an essential part of a liberal education What has to be avoided is not some degree of specialisation at VIth-form level but rather the necessity of a choice of specialism before that stage It is early specialisation, rather than specialisation itself, that is the danger A considerable degree of specialisation at VIth-form level is justified by the inclinations of the pupils, by the educational value of getting to grips with quite difficult work even at an early age, and by the simple fact that if some advanced work is not done at this stage, it must be done at the university It is uneconomic and frustrating, for example, to do premedical science at the university Most important of all, to delay specialisation means much longer university courses, and it is clear that these cannot be contemplated by a country that is having to strain its resources to meet its present needs for university places, even with a short university life

As regards the general education of the scientist, we are faced with a growing responsibility as the number and influence of scientists increases The nature of general education is itself doubtful It is clearly something much more than a body of information and implies the ability to think and discuss value judgments of a kind that do not usually arise in science itself The field is one that is confused by many fallacies—e g , the belief that it is an automatically broadening experience to study any subject that is unrelated to the student's specialist interest We should seek rather for courses which provide stimulus over a wide field—a stimulus that will lead to self-education The fashionable doctrine that " students educate themselves" is also only very partially true The value of residential universities lies partly in the adult guidance that can be given Having regard to the pressure of specialist knowledge and the social background of many of the students, it is difficult to resist the conclusion that the universities must play a more positive part in the general education of their students—e.g , by having arts tutorials for scientists Some of the best American practice is relevant here There can also be little doubt that the general education of our pupils suffers because they are allowed too little leisure, and great efforts will be called for to reduce the factual content of specialist curricula and the pressure of examinations

One thing is clear—that if our education of scientists, whether specialist or general, is to meet the very challenging prospect ahead, much depends on the quality of the individual teacher At the school level, this is the most serious and intractable of all our problems

NEW MALAYAN INSTITUTE OF PREVENTIVE MEDICINE

ON May 14, Sir Robert Scott, H M. Commissioner General for South-East Asia, formally presented the new Institute of Health to Singapore as a gift from the United Kingdom.

The institute houses the department of social medicine and public health of the University of Malaya and the health clinics run by the city council and the Government The staffs of these three authorities will thus join forces within the institute for the teaching and practice of preventive medicine. Dr T A. Lloyd Davies, professor of social medicine, has been appointed coordinator of research.

The building has cost 1¹/₄ million Straits dollars, which has been met by a grant from the Colonial Welfare and Development Fund It stands on land given by the Government of Singapore, valued at $600,000 UNICEF has contributed equipment and W.H.O staff

The clinics held at the institute will include sessions for maternity and child welfare, school and industrial health, dentistry, mass X-rays and B C.G vaccination, ophthalmology, and orthopædics The teaching includes courses for medical students, nurses, health inspectors, and anti-malaria inspectors The students will attend appropriate clinics and the teaching staff will share in running them. The institute stands in a crowded area of Singapore opposite the civil general hospital, and over a million attendances a year are expected

TOXÆMIA IN PREGNANCY

DESPITE efforts to curb that persistent malefactor, toxæmia of pregnancy, it is still contributing substantially to mortality for both mother and child At the first showing on May 30 of a new film, *Toxæmia of Pregnancy*, intended for the instruction of pregnant women, Prof R. J Kellar spoke sorrowfully of failure to reduce the damage done by this disease avoidable contributory causes were often neglected and early signs ignored, so that the power to control the disease by prompt treatment was lost If we were to make an impression on the mortality figures we must pay the closest attention to early signs, patients must be seen more often during pregnancy, and, Professor Kellar urged, prophylactic admission to hospital should be used more freely

The film, which was shown at the London headquarters of the National Birthday Trust Fund, was produced by Dr and Mrs W A. Bullen, with the obstetric advice of Miss Jean Burton-Brown, F R C.S , and sponsored by Pfizer Ltd Skilfully photographed in colour, it points good-humouredly to the dos and don'ts relevant to toxæmia. Mrs Stout, caught during a light snack at the fish-and-chip shop, Mrs Pale, a heavy smoker and inadequate eater, and Mrs Weary, struggling for prodigious hours a day on behalf of her large family, illustrate the don'ts The advice about diet includes the instruction to use salt in cooking but not otherwise The tone of the film seems exactly right for its purpose, and several obstetricians who saw it last week said how much they admired it

The film (16 mm, colour, 17 min) is available on free loan from the Pfizer Film Library, Folkestone, Kent

University of London

The following have passed the final examination for the degrees of M.B , B.S

Honours —Carys M Bannister (*d*), Charing Cross, K. A Barlow (*a*), King's College, M. S Everest (*a*, *c*), St. Mary's, L. J Farrow (*a*), St. Bartholomew's, Edward Friar (*e*), London, J J F Hamblin (*a*, *b*), London, A S Hartt (*e*), St. Thomas's, Margaret E. Hughes (*b*), Middlesex, Sheila M. University of Liverpool

Dr Thomas Wilson has been appointed senior lecturer in tropical hygiene with effect from April 1, 1959

Increased N H S Contributions

The increases in the weekly contribution to the National Health Service (6*d* for men, 4*d* for women 2*d* for juveniles, 2*d* for employers), which were authorised by the National Health Service Contributions Act 1958, will come into force on July 7

British Spas Federation

On Tuesday, June 10, at 6 P.M at 1, Wimpole Street, London W 1, Prof Howard A. Rusk, chairman of the department of physical medicine and rehabilitation, New York University, will give the Horder lecture. He will speak on crippled people in a troubled world.

Royal College of Obstetricians and Gynæcologists

At a meeting of council held on May 31, with Prof A M Claye, the president, in the chair, the following were elected to council

As representatives of the fellows J H Peel, T N A Jeffcoate, Robert Newton, J F Cunningham

As representatives of the members S D Loxton, J G Gallagher

The following were admitted to the fellowship

Joseph Bamforth, Janet Bottomley, Alexander Buchan, E W C Buckell, T St V Buss, T R Clarke, A G Cumming, A L Deacon, Aileen Dickins, J R Dickinson, G W Garland, E D Y Grasby, Freida Heighway, A F Hobson, R H Horner, Ursula M Lister, Ella A N Macknight, Eleanor M Mills, A A Moncrieff, Chunilal Mukerjee, P D Rajaratnam, E R Rees, Harold Renton, Ednyfed ap Iorwerth Rosser, J K Russell, Appacutty Sinnatamby, R B C Stevenson, D B Stewart, A H C Walker

The following were admitted to the membership

Vijayaratnam Balachandran, Bholanath Banerji, S K Basu, F X Bencini, Olga Bolitho, R T Booth, Carolina A Braga, A F Bushby, A S F Butcher, D P Das, F J de Maria, R E F Devitt, P H Drake, I M Duthie, Mary G Eldridge, Denys V I Fairweather, F G Feinstein, N K Ghose, F R G Gordon, H M Gough, J L Harington, G H Harris, J C Hartgill, C H Hodge, Helena E Hughes, A H John, Satyadev Khanna, Herbert Kramer, Dorothy K C Kwan, C N R Loveys, D J Mackay, Patricia C Mackay, Gillian G Matthews, R J Mitchell, Sukumar Mitra, A K Mukherjee, K D Mullen, Gunaratnam Muttuthamby, Brendan Needham, Jean M North, Joan North, O K Ogan, W H Patterson, P A Rachow, Krishna Sankari, R P Shearman, Bernard Shieff, Ma Khin Si, Devantala Singh, Margaret L Smith, I H F Swain, Mary A T Tolley, R D Upton, B C Uys, A J Van Amerongen, J A Verzin, D W Warrell, James Willocks

Society of Medical Officers of Health

Dr James Stirling, medical officer of health and school medical officer for Chesterfield, has been elected president of this society for 1958–59 in succession to Dr H D Chalke

Family Planning Association

The annual general meeting of this Association will be held today, Saturday, June 7, at 10 A M at Church House, Westminster, S W 1 Sir Russell Brain, the president, will speak at about 11 30 A M

Tritiated Steroids for Medical Research

Small amounts of the following labelled steroids are available through the generosity of the National Research Development Corporation, the Middlesex Hospital Medical School, and the Medical Research Council, for distribution to suitably qualified workers engaged in medical research

Progesterone, corticosterone, aldosterone, cortisol, aldosterone 18–21 diacetate, cortisol 21 monoacetate, corticosterone 21 monoacetate

Workers wishing to use these compounds each of which has a specific activity of 1–3 μC per μg , should apply to the secretary of the Clinical Endocrinology Committee, care of Dr M Gorrill, Medical Research Council, 38, Old Queen Street, S W 1, stating previous experience with tritium measurements and facilities available for the measurements, details of proposed experiments, including quantities required, and when and where the experimental work can start Approved allocations will be free except for a small charge to cover dispensing and transport

A New Voluntary Hospital

The new Victoria Hospital, Kingston, which is the first voluntary hospital to be started since the National Health Service began, was opened on May 21 Speaking at a meeting held in London to mark the occasion, Dr Bernard Lake, chairman of the hospital, recalled that seven years ago the South West Metropolitan Regional Hospital Board had closed the small local general-practitioner hospital serving Kingston and Malden and had turned it into a gynæcological department of Kingston Hospital A fund had at once been opened which had met with a response from all over the world, but it was largely thanks to the subscriptions of local people that it had proved possible to open the new 21-bed hospital The hospital, Dr Lake said, was entirely independent and could not be nationalised except by a fresh Act of Parliament It belonged to the local people, who had direct control through the committee which was elected by the subscribers Patients would be treated free of charge

Prof W J E Jessop and Dr R M Acheson have been elected fellows of Trinity College, Dublin

Dr J M Greenaway, of the University of Sydney, has been appointed as a Roussel fellow to work at King's College Hospital Medical School in the department of chemical pathology on the metabolism of radioactive adrenal steroids

Dr R S F Hennessey, head of the Wellcome Laboratories of Tropical Medicine since 1956, has been appointed to the new post of head of the therapeutic research division of the Wellcome Foundation Ltd Dr L G Goodwin succeeds Dr Hennessey in his former post

Captain J E Stone has retired from his post as director of the division of hospital facilities of King Edward's Hospital Fund for London Mr W E Hall succeeds him.

The address of the Central Midwives Board is now 39, Harrington Gardens, London, S W 7 (telephone Fremantle 4801–3)

At the summer meeting of the Medical Golfing Society, Dr J Park won the *Lancet* cup (scratch medal) and Dr E Canton Seward the Henry Morris cup

Ars Medica, a collection of medical prints made by the Philadelphia Museum of Art in 1952 with a grant from Smith Kline & French Laboratories Ltd , is being shown in London during June at the following places Royal Society of Medicine (June 2–6), Royal College of Surgeons (June 9–11), University College Hospital Medical School (June 12–14), London Clinic (June 15–18), Westminster Medical School (June 18–20), St Mary's Medical School (June 25 and 26)

Diary of the Week

JUNE 8 TO 14

Monday, 9th

University of London
5 30 P M (London Hospital Medical College, Turner Street, E 1) Prof Adrien Albert (Canberra) Chemical Aspects of Selective Toxicity
Postgraduate Medical School of London, Ducane Road, W 12
4 P.M Prof. J S L Browne Unusual Cases in Endocrinology
Institute of Obstetrics and Gynæcology
3 P M (Queen Charlotte's Hospital, Goldhawk Road, W 6) Prof J L Wright (Otago) Breech Delivery

Tuesday, 10th

Royal College of Physicians of London, Pall Mall East, S W 1
5 P M Dr J N Morris Coronary Heart-disease and Occupation (Ernestine Henry lecture)
Royal Society of Medicine
2 30 P M *Psychiatry* (Royal Infirmary, Sheffield, 6) Dr A D Leigh, Dr J W Sandler, Dr Max Hamilton, Dr R H Gosling Methods of Psychosomatic Medicine
Postgraduate Medical School of London
4 P M. Dr E J Zaimis Evaluation of Ganglionic Blocking Drugs
Institute of Dermatology, Lisle Street, W C 2
5 30 P M Dr I A Magnus Urticaria
Institute of Obstetrics and Gynæcology
3 P M (Hammersmith Hospital, Ducane Road, W 12) Professor Wright Vaginal Hysterectomy

Wednesday, 11th

Royal Society of Medicine, 1, Wimpole Street, W 1
4 30 P M *Physical Medicine* Dr M E Fearnley, Dr Michael Kremer Contribution of Physical Medicine to the Management of Multiple Sclerosis
Postgraduate Medical School of London
2 P M Prof L P Garrod Recent Developments in Antibiotic Therapy
Institute of Dermatology
5 30 P M Dr Henry Haber Dyskeratoses
Institute of Obstetrics and Gynæcology
3 P M. (Chelsea Hospital for Women, Dovehouse Street, S W 3) Professor Wright Enterocele
Institute of Diseases of the Chest, Brompton, S W 3
5 P M Mr N R Barrett Idiopathic Mediastinal Fibrosis
Oxford University
5 P M. (Radcliffe Infirmary) Prof John Browne Studies on Adrenal Cortical Function (Litchfield lecture)
Royal College of Surgeons of Edinburgh, Edinburgh, 8
3.30 P M Mr G A G Mitchell Innervation of Blood-vessels (Sir John Struthers lecture.)

Thursday, 12th

Royal Society of Medicine
5 P M *Ophthalmology* Mr E C Zorab, Mr J E H Cogan Erysiphake Extraction of Cataract
Postgraduate Medical School of London
4 P M Dr H E de Wardener Polyuria
Institute of Dermatology
5 30 P M Dr Arthur Tickner Serum Protein Patterns in Skin Disease
Nuffield Orthopædic Centre, Wingfield-Morris Orthopædic Hospital, Oxford
8 30 P M Mr A J Helfet Mechanism, Diagnosis, and Effects of Derangement of the Medial Meniscus of the Knee

Friday, 13th

Postgraduate Medical School of London
10 A M Sir Ralph Marnham *Management of Diverticulitis*
St Mary's Hospital Medical School, Paddington, W 2
5 P M Mr Aleck Bourne Non-Malignant Cervix.
Royal Victoria Hospital, Belfast
4 30 P M (Institute of Clinical Science, Grosvenor Road, Belfast) Prof Howard A Rusk (New York) Dynamic Therapeutics in Chronic Disease (Sir Thomas and Lady Edith Dixon lecture)

Saturday, 14th

Faculty of Anæsthetists of the Royal College of Surgeons of England, Lincoln's Inn Fields, W C 2
10 A.M Scientific meeting on Shock and Allied Phenomena

The Lancet · Saturday 14 June 1958

ENVIRONMENTAL FACTORS IN RESPIRATORY DISEASE [*]

D D Reid
M.D Aberd , Ph D Lond
READER IN EPIDEMIOLOGY AND VITAL STATISTICS,
LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, LONDON, W C 1

This country has long had an unenviable record in respiratory disease Dr William Farr himself remarked on the rising death-rate from bronchitis and pneumonia during the quickening industrialisation of the 19th century, and now the death-rate from chronic bronchitis among middle-aged men in England and Wales is by far the highest reported in the world If national vital statistics are to be believed, the Englishman between 45 and 64 is, at present death-rates, ten times more likely to die from either bronchitis or pneumonia than, for example, his contemporary in Denmark

Respiratory diseases, either trivial or grave, account for perhaps a third of the total sickness absence in British industry, and, although minor infections herald at least half of the serious infections of the lung, death from these complications is not their only major consequence Every year the examination of national service men re-emphasises the excessive incidence of disabling chronic middle-ear disease in men from the industrial areas of this country—districts already notorious for their high death-rates from bronchitis and pneumonia Voltaire once defended the English adoption of the Muslim practice of smallpox inoculation against the whisper of Christian Europe that the English were mad because "with a gay abandon, they gave their children a certain and dread disease in the hope of preventing an uncertain one" But as a lifetime opponent of laissez-faire, he would have been shocked by our almost complacent ignorance of the malign features of the urban environment which distort the course of respiratory infection to produce crippling and fatal disease

Vital statistics form the coarse sieve in epidemiological studies, sorting out the major factors in the ætiology of disease They clearly show that excessive mortality from respiratory illness is associated with the circumstances of life and work in the poorer parts of our industrial towns This rather vague generalisation has been explained by notions which usually reflect the special interests, the favourite theories, and even the political prejudices of the commentator With varying degrees of justice it has been asserted that more die of respiratory disease in poorer districts because of inadequate diet, less effective medical care, too short convalescence, repeated minor infections contracted in crowded houses, exhausting and dusty work, and life in a heavily polluted atmosphere As Sir George Baker put it in his lecture on the Devonshire colic to this college in 1767

> "A very small acquaintance with the writing of physicians is sufficient to convince us, that much labour and ingenuity has been most unprofitably bestowed on the investigation of remote and obscure causes Such a refinement in theory has, in several instances, been the parent of dangerous errors in practice men are apt to be as partial to their own conceits, as to their own offspring and these opinions seldom fail to govern at the bedside, which have been the result of much contemplation in the closet."

Our ideas about the ætiology of the respiratory disorders must still govern our practice in their treatment and prevention We cannot, therefore, remain satisfied with an impression that environmental factors bulk large as causes of respiratory diseases, such as chronic bronchitis, which are not invariably associated with any particular infecting organism To be effective, disease control must be based on a more precise assessment of the relative importance of each element in the environmental complex and the way in which conditions of life and work are related to the onset and outcome of respiratory illness With Baker, "we have learned not to indulge ourselves in visionary speculations, but to attend closely to nature"

The Home as a Focus of Respiratory Infection

It is natural that we should regard the home and family as the primary unit in epidemiological studies of the common infections of the upper respiratory tract. Some survey work of this kind has already been done In North America Dingle and his colleagues (1953) and Buck (1956) have studied the introduction and spread of colds in suburban middle-class homes In this country Lidwell and Somerville (1951) have surveyed the experience of colds among Wiltshire villagers More recently, Prof Robert Cruickshank, Dr G T Stewart, and I have sought to develop these family studies by combining bacteriological techniques with the traditional methods of clinical epidemiology (Brimblecombe et al 1958) At the same time we have tried to introduce some of the principles of research design now current in experimental medicine into the primarily observational science of epidemiology Our aim was to establish the relevance of certain aspects of the domestic environment of the family to the introduction and spread of these minor infections, which may be the forerunners of chronic respiratory disease

In essence, the ideas are simple The previous studies had established that the age and sex structure of the household, its size, and the presence or absence of a schoolchild, all seemed to affect the family experience of respiratory illness Each of these features of family existence is thus liable to complicate any comparisons made between families living in different conditions such as dampness and overcrowding Yet, if we are to assess the significance of these domestic factors, such comparisons are vital, and they might be obscured or confused by purely coincidental differences in family size or structure

Our primary interest was the effect of domestic overcrowding, and a first essential was thus to ensure that families living in different types of home should be as alike as possible in all other material respects

From among the families of children attending the out-patient department of Paddington Green Children's Hospital were selected all consisting of two parents and three children where one of the children had not yet gone to school From these families were taken only those living in self-contained homes, with no other members of the household, situated within 3 miles of the hospital These homes were then divided, according to our major interest, into groups of differing degrees of overcrowding, thus (*a*) families of five, living in 1–2 rooms were classed as "overcrowded", (*b*) families of five living in 3 rooms were classed as "crowded", and (*c*) families with 4 or more rooms were classed as "uncrowded" These families were then to be observed, by the same team of observers, during the same period At the same time assessments were made of other characteristics, such as degree of dampness of the house, parents' range of human contacts outside the home, and child physique and state of nutrition, which might affect liability to infection

---

[*] The first Milroy lecture for 1957, delivered to the Royal College of Physicians of London on February 5, 1957

This was certainly not an experiment, but it was a planned observation, and, as in experiment, the criteria of assessment were crucial Two groups of epidemiological measures were used the first clinical, the other bacteriological Every fortnight the families were visited by a pædiatrician (Dr F Brimblecombe) or a nurse (Miss Dorothy Sanderson) who elicited a careful history of the onset, nature, and course of any respiratory infections in the family during the preceding two weeks Throat and nose swabs were also taken from every member of the family every fortnight The fact that swabs were obtained on 95% of the possible occasions is surely a tribute to their tact and pertinacity

The clinical information was then used to plot the introduction of clinically apparent infection into the family and to track the extent and course of its spread from person to person in the household The summation of many little family outbreaks allowed us to calculate appropriate measures of the epidemic experience of groups of families living in contrasting domestic circumstances In the same way modern techniques of organism typing, applied in this study by Dr Peter Masters and his colleagues, allowed the findings on throat and pernasal swabs to be used to confirm or modify conclusions based on the clinical data The recovery of a type-15 pneumococcus from a family in which that specific organism had not been recently found is treated, by analogy with clinical experience, as a new introduction Its serial appearance in other members of the family can then be used to trace its spread through the household It should be emphasised that, although pneumococci are rather more often recovered from the throat during attacks of coryza, no causal relationship is implied. These type-specific strains are here used simply as readily identified indicators of the familial paths of infection of the nose and throat Their merit lies in the fact that they are more likely to be independent of the differences in susceptibility which may obscure the significance of clinically evident infection

Preliminary sifting of the evidence showed no significant or consistent relation between the frequency of colds and dampness in the home, apparent standards of maternal care, family diet, and the likelihood of extrafamilial contacts But there was a suggestion, based on rather small numbers in the worst group, that the adequacy of the child's clothing for the prevailing climate might be relevant The only technically significant association found was between overcrowding and the incidence of coryza Our concentration on this point thus seems to be justified

To show that overcrowding is apparently important is not enough We need to know, for example, whether the clinical appearances are in fact due to changes in effective contact-rates In other words, we want to determine whether overcrowding increases the frequency and duration of contact intimate enough to allow transfer of infection Alternatively we may ask whether the high attack-rates in overcrowded homes are simply an expression of some other quality of physique or morale, unrelated to the load of infection, of families who live in bad conditions At the same time it would be useful to understand more about the part played by its several members in the introduction and spread of respiratory infections in the family

For these reasons we have summarised our experience in these family epidemics firstly, by calculating clinical measures of introduction and spread The frequency in each crowding group of new cases (i e, cases arising ten days or more after the last previous case in the family) in every 100 weeks of family experience differs little between crowded and uncrowded homes On the other hand, the measure of spread given by the secondary-attack rate—i e, the percentage of those exposed to an index case who show the same syndrome during the ensuing family epidemic—rises consistently from 13·5 to 17·4% with increasing crowding in the home Changes in the ease of spread rather than excessive introduction-rates are thus apparently responsible for the higher attack-rates in crowded homes When the secondary-attack rate is compared with corresponding rates of bacterial transfer (see accompanying table) it becomes quite clear that the clinical appearances are not the result of any lowered threshold of resistance or reporting but a physical effect of the greater transfer of infection in the more crowded homes

CLINICAL AND BACTERIOLOGICAL MEASURES OF TRANSFER OF INFECTION IN DIFFERENT HOUSING CONDITIONS

—	Type of housing		
	Uncrowded	Crowded	Overcrowded
Clinical secondary-attack rate (%)	13·5	16·4	17·4
Bacterial-transfer rate (%)	11·2	13·8	16·0

Family Status in the Introduction and Spread of Family Infections

In the same way, introduction and spread according to the family status—e g, father or pre-school child—of the individual apparently introducing infection into the family can be studied by bacteriological as well as clinical means Fig 1 shows apparent clinical introduction and secondary-attack rates according to the family status It would seem that, on clinical grounds at least, the pre-school child is in these social circumstances the most frequent introducer of new infections The spread following introduction—i e, the secondary-attack rate among the rest of the family—is apparently greatest when the index case is a school child

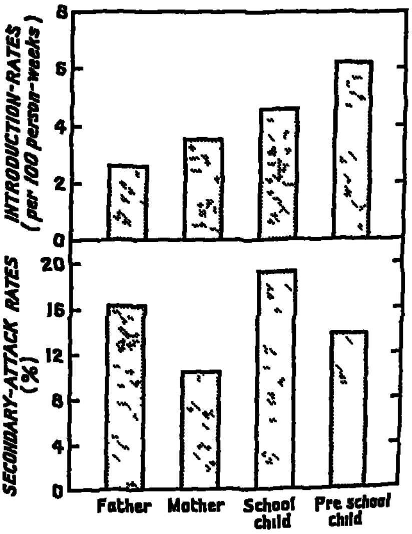

Fig 1—Clinical measures of introduction and spread of respiratory infection by family members

These tentative conclusions must be tempered, however, by realisation that the secondary-attack rates following a father's cold among the remainder of his family are based on the number of attacks among younger and more susceptible individuals The converse holds for the youngest child when colds have to spread against the greater resistance of older people Spread is thus likely to be overestimated for father and underestimated for the youngest child

Some adjustment can be made for this differing susceptibility in those exposed to colds brought in by the various members of the family

The spread following the mother as the index case can be compared with that following a cold in a pre-school child by calculating the secondary-attack rate among the remaining three members of the family (father and the two older children) after each type of exposure In this way the experience of the mother can be used as a standard and each member of the family compared in turn with her Similarly, the susceptibility of, say, mother and child can be compared by the frequency of clinical signs after exposure to colds introduced by the three other members of the family

The interpretation of the clinical data requires some such adjustment for susceptibility If the load of infection encountered outside by the schoolchildren and their younger pre-school siblings were in fact the same, the younger and more susceptible child would be the more likely to appear as the first case in a family epidemic Fig 2 shows that this is in general true, once differences in susceptibility have been taken into account, the introduction-rates become much more alike In short, the chance of bringing home a cold largely depends on personal susceptibility There remains, however, the suggestion that, even in the congested districts round Paddington, the schoolchild is more heavily exposed to infection from outside the home and spreads it within the family much more effectively than anyone else

This conclusion can be tested by comparing, as in fig 3, these clinically determined ratios with the evidence given by the frequency of introduction of new type-specific strains and the rate of their spread from the introducer to the remainder of the family As before, the results for each family member are compared with the mother, but, since the presence of type-specific bacteria in the nasopharynx is being used simply as an indication of mechanical transfer rather than of clinical infection, no correction for immunity has been made Remembering the inevitable crudity of both types of measure, there is an interesting consistency in the pattern, if not in the absolute values, obtained by each approach The bacteriological findings reinforce the slight clinical suggestion of greater exposure outside the home among the schoolchildren They also display an interesting contrast between the experience of mothers and fathers Although organisms new to the family are found more often among the fathers, fathers (because of their higher resistance to infection) appear less often as the introducing case in family epidemics The converse is true for mothers Implicit in this result is the suggestion that the higher incidence of colds among young adult females is an expression of a real increase in susceptibility rather than of any tendency to report minor ailments more easily This result would agree very well with the higher " take " rates among women volunteers in experimental infections at the Common Cold Unit at Salisbury and the higher attack-rates for " colds " in industrial records of sickness absence

Home and School Sources of Throat Infections

On epidemiological grounds the common cold, with running nose and mild fever, could be differentiated from infections presenting with acute sore throats, perhaps with obvious local inflammation, adenitis, and pyrexia With such sore throats not only the seasonal swing but the age-distribution of cases differs from those with coryza The steady fall in the coryza attack-rate from infancy onwards contrasts with the rising " sore throat " attack-rate among the older schoolchildren Bacteriologically there was no very constant association between " sore throat " and the presence of hæmolytic streptococci either in the patient or in the other members of his family at the same time, and it seems likely that more than one organism can be responsible for the clinical syndrome of acute sore throat Nevertheless, there is an agreement between clinical indications and bacteriological results which re-emphasises the importance of the schoolroom as an environment which favours the spread of this particular type of disease of the upper respiratory tract

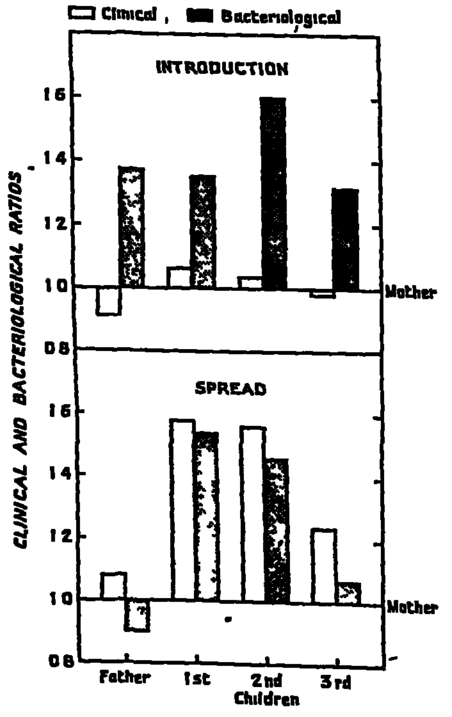

Fig 2—Clinical and bacteriological indices of introduction and spread of infection by family members.

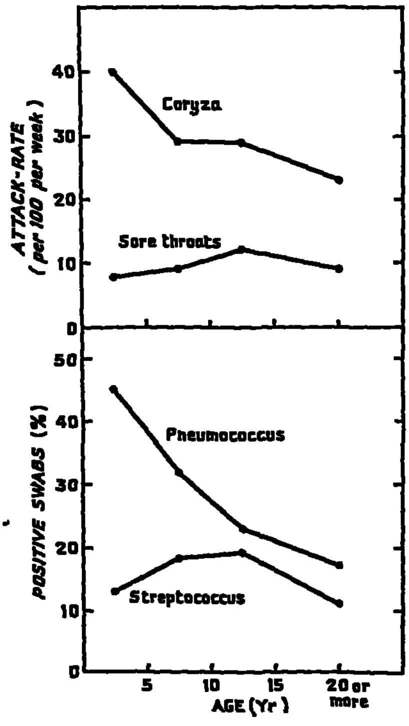

Fig 3—Age-trends in rates of incidence of respiratory infections and bacterial carriage

Although broadly similar, there were intriguing discrepancies between our findings in Paddington and those in other studies both in this country and in North America Our initial impression of the importance of the pre-school child as an introducer of infection to the household contrasts with the American finding of the schoolchild the main culprit Again, while the " coryza " attack-rate among our children dropped steadily from infancy onwards, the rate in the American studies rose to a peak only after the age of 3 It now seems clear that, compared with the sheltered existence of middle-class suburban families in Cleveland or the villagers of Wiltshire, the pre-school child in a congested metropolis is exposed, when at his most susceptible, to a heavier load of infection outside the home And this, when combined with the effect of severe overcrowding within the home, explains a part, but only a part, of the city child's adverse experience of respiratory disease

Spread of Infections in Classrooms

Despite this effect of the urban environment on the incidence of colds among the youngest children, there stands out in all these studies the clear suggestion that, next to the home, the schoolroom may be a principal epidemic focus of colds in the community

The classroom environment may affect the incidence of respiratory disease in two ways—either by affecting the ease of spread or by lowering the individual's resistance to infection Both these possibilities have been studied in some work which also sought to exploit the combined use of bacteriological techniques and clinical epidemiology In this instance, however, the bacteriological data were obtained, not from swabbings of the throat and nose, but by counts of the number of organisms found in samples of air drawn from classrooms in daily use

The history of the development of air-sampling has been recounted by Dr R E O Williams in his 1956 Almroth Wright lecture at St Mary's Hospital

> The notion that counts of bacteria in the air might be useful indicators of the risk of respiratory disease is by no means new In the 1890s, Carnelly et al (1887) tried to relate the number of organisms settling on agar plates in the overcrowded houses of the poorer parts of Dundee to the mortality from respiratory disease in the same districts at that time With commendable courage they visited Dundee homes between midnight and four in the morning to expose plates in rooms where up to eight people might be sleeping (*Only once, they assert, were they received uncivilly*) It was perhaps hardly surprising that they were able to show that the number of organisms of all kinds found in the air was seven times higher and the mortality appreciably greater in one-roomed houses than in four-roomed houses in Dundee at that time These workers could not and did not claim that they had demonstrated any very direct cause-and-effect relationship Very little has been done since then to test the practical validity of air-sampling as a measure of air hygiene—i e, an index of the risk of the airborne spread of disease in occupied spaces
>
> During the earlier part of this century, interest in the possibility of any widespread aerial dissemination of infection languished The work of Flugge (1897), for example, appeared to show that infected droplets emitted from the nose and throat of a patient by speaking or coughing were carried only a yard or so from the patient's mouth Again, since no tubercle bacilli were recovered from the air of rooms inhabited by patients with that disease, this too seemed to dispose of the idea that respiratory infections could be effectively spread by widely circulating infective droplets in wards or other occupied rooms
>
> In the 1930s, however, Wells (1933) introduced more efficient methods of sampling the bacteria suspended in room air and showed quite conclusively that organisms could be recovered from the air at considerable distances from their human source It appeared that these organisms were projected from the mouth in droplets of moisture which became lighter as the moisture evaporated and were carried on air-currents quite widely across the room Only the larger and heavier droplets fell almost at once to the floor But, as Williams pointed out, these were the only droplets effectively caught on the plates used by Flugge as a sampling mechanism Flugge's restricted views on the feasibility of infection being spread in widely disseminated nuclei thus stemmed from a limitation imposed by his own technique
>
> At this stage it would be a gratifying exercise for a teacher of epidemiology in the older fashion to point out how neglect of the simpler methods of direct field observation had stultified progress Unfortunately, the whole burden of field inquiries during this century led Stallybrass to remark in 1931 "Gone are the conceptions of the miasmas, the malarias, the pythogenic or filth originating diseases in their original meanings and with the miasmatic theory has gone the general conception of air-borne infection " Experience in the infectious disease hospitals certainly accumulated to show that measures to limit transmission by fairly close contact were enough to prevent serious cross-infection (Harries 1935)
>
> But some fragments of epidemiological evidence obstinately remained to suggest the possibility of airborne spread of infection Stallybrass himself quotes a suggestive experience reported by the U S Public Health Service during the 1918 influenza epidemic A prisoner from a distant town entered an American prison on an evening when a concert was being held there He failed to report sick but went to the concert instead His movements, seating, and contacts were, inevitably, both strictly prescribed and well known Yet he infected several other prisoners in the room seated at distances far beyond the range of Flugge droplets Observations like these gave fresh interest to the work of Wells on widely floating particles ejected from patients' mouths as a source of epidemic infections Wells et al (1942) also claimed to have reduced the incidence of specific infections in schools by using germicidal ultraviolet-ray screens in classrooms to prevent the wide dissemination of infection from an affected child

Experiment in Air Hygiene in Schools

These were important findings and the Air Hygiene Committee of the Medical Research Council (1954) set up a large field trial to see whether, in primary schools of the compact London suburb of Southall, these results could be repeated The experimental plan was quite simple

> In three Southall primary schools, ultraviolet-ray lamps were installed in classrooms, assembly halls, and cloakrooms so that their rays, projected upwards to the ceiling, formed a bactericidal barrier through which infected droplets would have to pass in the normal course of room ventilation Such an arrangement could have no effect on direct contagion In three other Southall schools, whose past experience of infectious disease had been similar, no ultraviolet-ray lamps were fitted, but precisely the same observations were made there during the three years of this field trial These observations included complete recording of the sickness experience of all the pupils in these schools Regular visits were also made to randomly selected classrooms in every school Samples were drawn from the air by the slit-sampler developed by Dr O M Lidwell, and a note was made of those characteristics of the classroom environment (such as indoor temperature, relative humidity, and ventilation) which might have some effect on the incidence and airborne transfer of infection At the same time assessments were made—on a rather subjective basis—of the amount of talking and activity of the class, since both these aspects of class behaviour are likely to increase the bacterial content of the air

This field trial aimed at determining whether the interruption of the aerial routes of transfer by the bactericidal ultraviolet rays would result in any general lowering in the incidence of the presumably airborne respiratory infections or a *fall in the cross-infection* rates within classrooms of the specific infectious illness such as measles and chickenpox But as a useful by-product of this investigation Dr Robert Williams, Dr Owen Lidwell, and I were interested in the prospect of finding out whether the bacterial counts in samples of air in classrooms could be used as an index of the risk of cross-infection among the children there Two kinds of media were used in the slit-sampler, the first was a selective medium which allowed colonies of *Streptococcus salivarius* to be recognised and counted with ease, the other was serum-agar, which, being non-selective, allowed a " general flora " count of all kinds of organisms in the sample of air

Sickness experience was measured in two ways For measles it was possible to plot the course of classroom epidemics from the date of onset of absence of the first or index case to the wave of secondary cases between the 7th and 16th day thereafter The secondary-attack rate among those pupils who had never had measles before could thus be used to measure the risk of transfer For the non-specific upper-respiratory-tract infections no such precise measure of transfer risk was practicable The crude incidence-rates had to be used instead

These measures of sickness were accumulated over the school year for a particular classroom and then related to the average of the readings of temperature, ventilation, or bacterial counts made in that room at intervals throughout the school year The basic assumption is that the teacher in charge is fairly consistent in her standards of suitable room temperature and class behaviour Unfortunately, from the point of view of analysis, the most talkative classes tend to be at once the most active, the youngest, and the most susceptible Some preliminary analyses showed that the *Streptococcus salivarius* was more closely related to talking, while the " general flora " count seemed to be a better index of the amount of air pollution by activities which disturbed secondary reservoirs of infection on clothes or in floor dust Statistical techniques of partial correlation analysis are, therefore, required to allow, for example, for the fact that warmer rooms tend to have a lower " colds " incidence and lower measles secondary-attack rates

Despite these complexities, we found that there was a significant relation between the *Strep salivarius* count and the measure of transfer of measles infection in the classrooms given by the secondary-attack rate (fig 4), and this relation was not materially affected by adjustments for simultaneous variations in the classroom environment or pupil behaviour

On the other hand we could demonstrate no significant relationship between the incidence of colds and the corresponding *Strep salivarius* counts There was, however, a clear suggestion that the incidence of these disorders was related to the general flora count in the same classroom

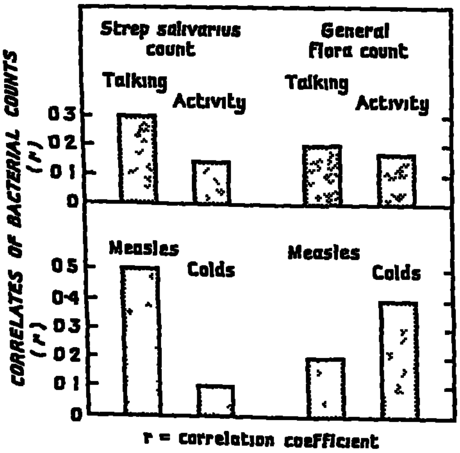

Fig 4—Net correlation of air counts of bacteria in air with classroom behaviour of schoolchildren and incidence of measles and colds

Two suggestions emerge from these results Widespread aerial dissemination of infective droplets is apparently important in the spread of measles On the other hand, the more direct transfer produced either by physical contacts, droplet spray at close range, or activity stirring up secondary reservoirs of infection in clothes or dust is the more likely mode of spread of colds in classrooms When the results of the main trial itself are reviewed, they certainly appear to be consistent with these hypotheses The ultraviolet irradiation produced both a large decrease in the counts of *Strep salivarius*, which were used as indicators of widespread air pollution from the respiratory tract, and some reduction in the incidence of measles But the bactericidal barrier against long-range transfer of infected droplet nuclei had little effect either on the counts of general flora, dispersed by activities likely to favour more immediate contagion, or on the incidence of the common cold

Some Practical Conclusions

Lord Macaulay once said that " Facts are the mere dross of history It is from the abstract truth which interpenetrates them, and lies latent among them like gold in the ore, that the mass derives its whole value " But to extract the absolute truth in a science like epidemiology, based on observation rather than experiment, is much less easy than Macaulay makes it sound Certainly neither bacteriological investigations nor clinical field studies can claim any monopoly as paths to the ultimate secrets of the epidemiology of the common cold But, used together, they hold out some hope of discovering the common thread that explains the pattern of assembled facts Bacteriological opinion may have swung too violently from a denial of the possibility of any wide airborne spread of disease to an overestimate of its potential importance in the ubiquitous upper-respiratory-tract infections Clinical studies, conducted in parallel, have led to a more balanced assessment On the other hand, the results of clinical inquiries may be obscured by wide differences in resistance, bacteriological findings have then clarified the route of infection in family outbreaks of respiratory disease Agreement between clinical and bacteriological results brings added confidence, and in these combined studies they do show that passage of colds apparently depends much more on the direct and intimate contact of overcrowded homes or noisy classrooms full of active children than on any widespread dissemination of droplet spray

The late President Roosevelt was reputedly fond of saying that " Politics is the science of the possible ", and the same principle of limiting anticipated ends within available means applies equally to preventive medicine Hopes for the control of the common cold rest on the belief that the aerial transfer of infection can be effectively blocked The work now reported leads, I fear, to a more tempered view

In the Royal Air Force, Air Commodore T C Macdonald and his colleagues (1955) have shown that what might be termed " blunderbuss " measures designed to block all possible aerial routes of spread by ultraviolet lamps, oiled floors, and screens between beds have had no effect on the incidence of upper-respiratory-tract infection in Service barracks The failure of such attempts to prevent epidemics of colds in communities could be explained if ubiquitous cold virus infection appears clinically in a seasoned population only after exposure to large doses at close range

My aim is to preach, not nihilism, but realism, for there are likely to be many environments—as in the medical laboratory, the postmortem room, or the operating-theatre—where quite small doses of airborne organisms may infect susceptible individuals at long range Here there is immediate scope for more research by the combined approach on the practice of air hygiene, but it is hard to be sanguine about its value against the common cold

CHIEF THERAPEUTIC DIETICIAN, ROYAL VICTORIA HOSPITAL, BELFAST

Low body-weight is common in patients who have had operations on the stomach It may represent loss of weight after operation or failure to regain completely weight which had been lost before It often causes concern to the patient, and may prevent him from doing heavy work (Moroney 1953) It is occasionally associated with pulmonary tuberculosis (Pulvertaft 1952, Pearson 1954)

Many of the factors that influence the weight-loss are well-known It is related to the extent of the resection, being greatest in those who have lost the whole stomach (Zollinger and Ellison 1954) It is also influenced by the type of the anastomosis A Billroth-I gastrectomy causes less loss of weight than a Polya (Moloney 1954, Wollaeger 1950), and probably less than simple vagotomy and gastroenterostomy (Zollinger and Ellison 1954) Women are more prone to be underweight than men (Blake and Rechnitzer 1953, Anderson et al 1955)

There are two known causes of low weight

(1) A reduced intake of food may be the result of a poor appetite, a reduced capacity, or postcibal symptoms This is probably the main cause, but little is known of its quantitative aspects

(2) There is often an increased loss of food derivatives, particularly fat and nitrogen, in the fæces It is rarely great enough to influence body-weight significantly except in those who have undergone total or near-total gastrectomy

Some patients remain underweight even when they appear to be eating enough and not to be losing an excess of calorific material in their fæces

Various forms of treatment, designed to improve weight, have met with varying success

The intake of food can be increased by giving small, frequent feeds with a high calorific value and low bulk A slight gain in weight may follow (Brain and Stammers 1951, Ellison 1955, Lepore 1956)

Attempts to increase the absorption of fat and nitrogen by feeding pancreatic extract, bile salts, or emulsifying agents have produced no beneficial effect (Ward-McQuaid 1949, Ellison 1955)

Operations which relieve postcibal symptoms (conversion to Billroth-I or Roux-en-Y anastomosis, &c) often cause a striking gain in weight (Perman 1951, Capper and Welbourn 1955)

Testosterone, given to patients who are underweight after total gastrectomy, improves appetite and food intake (Van Wayjen 1957), but its effects on body-weight are not known

The present investigation has three parts The first is concerned with some further factors which influence body-weight after gastrectomy The second is a quantitative study of the relation between food intake, postcibal symptoms, and body-weight The third is a controlled trial of various methods of increasing the weight of those who have lost it The first two were made by one of us (Welbourn 1953) some years ago in the department of surgery, Liverpool University

Factors Influencing Body-weight

209 patients who had undergone gastrectomy of various types were studied

There were 174 men and 35 women 170 had had subtotal (three-quarters) resection, with a Polya-Finsterer anastomosis, for peptic ulcer A few had had less radical resections with the same (16) or a Billroth-I (9) anastomosis Some had undergone œsophagogastrectomy (8) or total gastrectomy (6) for carcinoma of the œsophagus or stomach or for benign lesions

The patients fell into two groups of approximately equal size Those in the first had had their operations one to five years previously, and those in the second six to fifteen years previously In all cases the patient's own estimate of health weight (i e, his weight before development of the lesion which led to operation) was recorded The weight at the time of operation was obtained from the case-sheet and the weight at the time of follow-up was measured

Simple inspection of the data revealed that, on the whole, those who had lost much weight before operation tended to regain it after, while those who had maintained weight and the few who had gained weight up to the time of operation tended to lose it afterwards This point was investigated further by comparing the relation between the preoperative and the postoperative changes in weight for all the patients (fig 1) The correlation between the two was highly significant ($P < 0\ 001$) The middle sloping line on the graph represents the regression of the postoperative change (y) on the preoperative change (x) That is, it shows how, on the average, y is influenced by x The two outer sloping lines are drawn at two standard deviations from the regression line, so that they contain

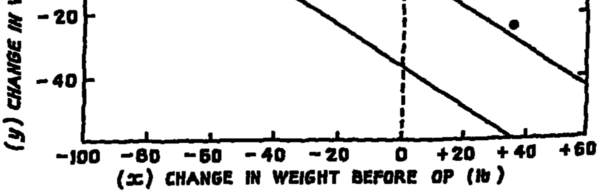

Fig 1—Weight changes before and after gastrectomy Average postoperative change for given preoperative change

x, change in weight before operation in lb (i e, preoperative weight minus health weight)

y, change in weight after operation in lb (i e, postoperative weight minus preoperative weight)

$r_{xy} = -0\ 67$ $P < 0\ 001$ $\hat{y} = -0\ 656x - 5\ 445$ $s_{y\,x} = 15\ 55$

= mean $\bar{y}$ for given arrays of x

Middle sloping line = regression of y on x

Outer sloping lines = $\pm 2s_{y\,x}$

between them about 95% of the observations Inspection of this graph shows, for instance, that on the average a patient who loses 80 lb before operation ($x=-80$) gains 47 lb afterwards ($y=+47$), one whose weight does not change before ($x=0$) loses 6 lb after ($y=-6$), and one who gains 20 lb before ($x=+20$) loses 19 lb after operation ($y=-19$)

This finding can be illustrated in another way The 170 patients who underwent subtotal gastrectomy with a Polya-Finsterer anastomosis for peptic ulcer can be divided arbitrarily into three groups on the basis of the preoperative change in weight (fig 2) Group A (57% of the patients) remained within 15 lb of their health weight up to the time of operation, on the average they lost 3 lb before operation and another 4–6 lb afterwards Group B (42%) lost 15 lb or more before operation, their average loss being 35 lb After operation they *gained* an average of 20 lb, but remained a little lighter than those in group A. The average weights of those in groups A and B who were seen one to five years after operation were almost identical with those seen six to fifteen years after This indicates that, although the weight changes rapidly in the first year after operation, it alters very little later Group C (1%) *gained* 15 lb or more before operation, their average gain being 43 lb After operation they lost 20 lb but remained well above their health weight.

Although we have not presented the results for the two sexes separately, our data confirm that women tend to be relatively more underweight than men both before operation and at all periods after

Food Intake, Postcibal Symptoms, and Body-weight

Two groups of 15 patients, who had undergone subtotal gastrectomy for peptic ulcer at least a year previously, were investigated Those in group I ("normal weight") had gained weight since operation and weighed at least as much as they did in health. Group II ("low weight") had lost 15 lb or more since operation and were, on the average, 29 lb below health weight The average daily consumption of food was estimated by obtaining from each patient a complete list of what he had eaten during one week and discussing it with him The composition of the food was calculated from standard tables (McCance and Widdowson 1946) Each patient's requirement of calories was estimated by questioning him about his occupation and habits and assigning him to one of seven "degrees of activity" (British Medical Association 1950) The severity of any postcibal symptoms from which he suffered was also assessed

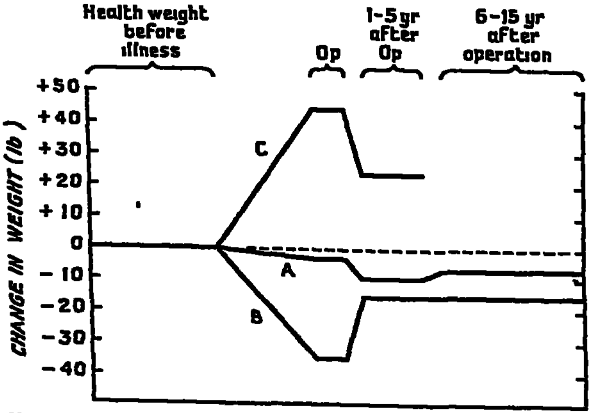

Fig 2—Effect of subtotal gastrectomy on body-weight. Mean weight in relation to health weight, at various periods, in three groups of patients.

A, within 15 lb of health weight up to the time of operation B, lost 15 lb or more before operation C, gained 15 lb or more before operation

TABLE I—INTAKE OF CALORIES AND PROTEIN AND INCIDENCE OF POSTCIBAL SYMPTOMS IN RELATION TO BODY-WEIGHT AFTER GASTRECTOMY (14 PATIENTS IN EACH GROUP)

—	Normal weight	Low weight
Calories		
Mean daily intake		
Actual	2955	1910
Required	2910	2535
Actual intake as proportion (%) of theoretical requirement	102 (S.D 31)*	76 (S.D 20)*
Protein		
Mean daily intake (g)	73	55
Mean proportion (%) of calories provided by protein		
Actual calories	10	12
Required "	10	9
Postcibal symptoms		
No having		
Nil	7	1
Mild (fullness only)	6	3
Moderate	1	3
Severe (incapacitating)	0	7

* Statistical analysis comparing the two means, $t=2\cdot671$, D F $=26$, $0\cdot01 > P > 0\cdot02$

The results are shown in table I Those with normal weight were eating an average of 102% of the calories which they needed theoretically, while those with low weight were eating only 76% This represents a mean deficit of over 600 calories a day in the second group, and is probably enough to account for most of their loss of weight

The daily requirement of protein in health is not known exactly, but it is recommended (British Medical Association 1950) that at least 11% of the total calories should come from this source Those in the group with normal weight were obtaining 10% of their calories from protein Those who were underweight were eating enough protein to provide 12% of their actual calorie intake, but only 9% of the calories they needed There was considerable variation around these means, but it is doubtful whether many patients were greatly deficient in protein

TABLE II—INFLUENCE OF POSTCIBAL SYMPTOMS ON BODY-WEIGHT

—	Severe symptoms (30 patients)	Symptoms absent or mild (45 patients)	χ^2	P (1 D.F)
No with normal weight	4 (*13*%)	19 (*42*%)	7·07	< 0·01
No with low weight	18 (*60*%)	15 (*33*%)	5·21	< 0·05

The severity of postcibal symptoms was much greater in those who were underweight (table I) and accounted for the most part for their reduced consumption of food

The relationship between postcibal symptoms and body-weight was also looked at the other way round—that is, by comparing the number of individuals of normal weight and of low weight (defined as above) in a group of 30 patients with severe postcibal symptoms with the number in a group of 45 who had no symptoms or only mild symptoms The results are shown in table II It is clear that, although severe symptoms were often associated with low weight and mild or absent symptoms with normal weight, the association was far from complete Indeed, a third of those whose postcibal symptoms were minimal were 15 lb or more below their health weight.

Comparative Trial of Methods of Increasing Weight

40 patients who had undergone gastrectomy for peptic ulcer at least two years previously, and who had lost 14 lb or more in weight since, were selected They were on the average 24 lb below their health weight and 25 lb below standard weight *

Preliminary investigations were done in all 5 patients who were anæmic were treated with iron intramuscularly before being included in the trial Correction of the anæmia did not alter their weight The plasma-protein contents were normal in all Chest radiographs showed evidence of healed tuberculosis in 10 patients, in 2 of these the disease had developed after gastrectomy No patient had symptoms of recurrent ulceration Those with severe postcibal symptoms were deliberately excluded from the trial, because they needed treatment by other methods, but 7 had moderate or mild symptoms

Dietary analysis in 12 patients showed a deficit of over 1000 calories a day, which was even bigger than that found in the previous investigation The percentage of calories provided by protein was, however, the same

The patients were allocated at random to one of the following six treatment groups (males only were placed in group 5) (9 patients, after failing to respond in one group, were transferred at random to another)

1 Control (dummy tablets, consisting of flavoured chalk), 8 patients

2 Intramuscular iron (' Imferon ') 5 ml once weekly, 10 patients This was used because it regularly causes increased consumption of food and increase of weight in gastrectomised rats (Welbourn and Doggart 1956, Johnston and Welbourn, unpublished)

3 Intramuscular vitamin B_{12} (100 µg once weekly), 7 patients This was used because its use in the treatment of megaloblastic anæmia following total gastrectomy (Welbourn et al 1956) often causes an increase in weight, and 1 patient who was underweight after partial gastrectomy gained 12 lb in six months while receiving it from her practitioner

4 Dietary supervision by one of us (K A), 10 patients The purpose was to increase the daily calorie and protein intake by (a) the addition of extra protein (meat, eggs, fish, &c) to the three main meals, (b) a daily milk intake of two pints, (c) the addition of a protein supplement (equivalent to 30 g of casein) to one of the pints of milk, and (d) two-hourly high-calorie snacks between the main meals Each patient was seen fortnightly Some needed humouring, while others needed financial help All were given a reasonably free rein where likes and dislikes were concerned

5 Testosterone (sublingual tablets of methyltestosterone, 25 mg daily), 7 patients This was used because of its anabolic effect, debilitated patients rapidly regain weight and strength on this therapy (Reifenstein and Albright 1947) Only male patients were placed in this group because of the possibility of virilisation

6 Iproniazid, 50 mg a day by mouth, 7 patients This was used because of its effect in stimulating appetite (Marks 1957, Scherbel 1957)

All the patients were weighed at the beginning of the investigation and regularly during it The trial was " blind " in that the patients knew that we were trying to help them, but (except for those in group 4 from whom the facts could not be concealed) did not know what treatment they were receiving or that we were particularly interested in their weights

The results are shown diagrammatically in fig 3, which records the total weight changes at the end of eight weeks' treatment No significant change was observed in the control group or in the groups who received iron intramuscularly or vitamin B_{12} Significant gains in weight were found in those who had had dietary supervision, methyltestosterone, or iproniazid The average increase in each group was about 4 lb

Dietary supervision increased the weight in every case, but it was time-consuming and demanded considerable efforts by the patients Moreover, gains that had been achieved with patience were easily and quickly lost if illness or other mischance interrupted the routine

Methyltestosterone was less consistent in its effects 2 patients gained 8 lb in as many weeks, 1 gained nothing, and 1 lost a pound No side-effects were observed. All those who gained weight reported an increased sense of well-being, and 4 of the 7 said that their appetites had increased

Iproniazid was also variable in its effects, but all the patients put on weight, 1 gaining 10 lb and another 8 lb 5 of the 7 patients remarked spontaneously that their appetites had increased and that they were eating more No toxic effects were observed

Continuation of treatment beyond eight weeks caused further slight increases in weight in the methyltestosterone and diet groups (1 patient in the former gained 12 lb in twelve weeks), but not in the iproniazid group Cessation of treatment was often followed by loss of the weight which had been gained

Discussion

The direction of the preoperative change in weight is the most important single factor determining the direction of the postoperative change, and must be taken into account when other factors (such as the type of operation) are being examined The data presented in fig 2 (groups

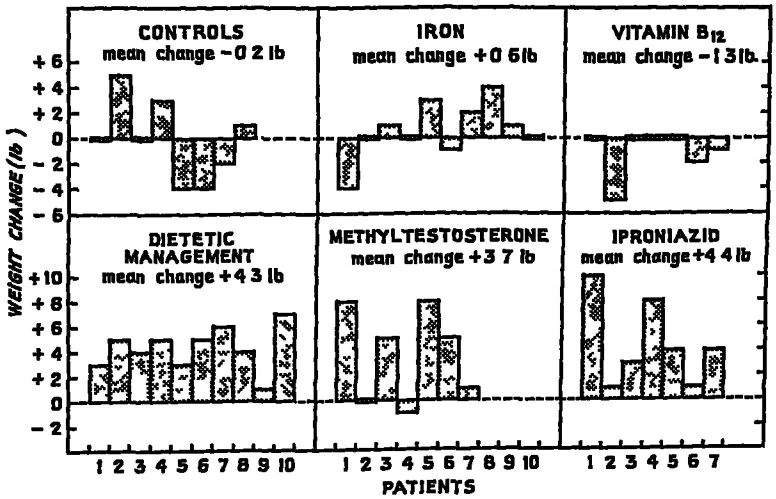

Fig 3—Results of treatment designed to increase body-weight after gastrectomy

Statistical analysis

Controls, iron, and vitamin B_{12}—changes not significant

Iproniazid—t (paired data)=3 4 D F =6 0 02>P>0 01

---

* The standard weight, calculated in relation to sex, height, and age (Kemsley 1952) was taken into account in this investigation because Baron (1954) had pointed out the unreliability of the health weight Although we found, in general, a close correlation between the two (r=+0 84, in 45 observations, 0 01>P>0 001), 5 patients, who were well below their health weights, were excluded because they were in fact at or above their standard weights)

A and B, who account for 99% of the patients) suggest that, whatever the preoperative weight, subtotal gastrectomy tends to make patients assume on the average a final weight 7–15 lb below the health weight The fact that those patients who lose much weight before operation end up 6–8 lb lighter than those who do not, indicates probably that it is harder to regain weight which has been lost than it is to maintain weight at a steady level

An inadequate intake of food clearly accounts for most of the cases of low weight However, in the low-weight group (second investigation) 1 patient was taking 120%, and a 2nd patient 97%, of his theoretical requirements Conversely, in the normal-weight group 3 patients were taking less than 70% The methods of assessing food intake and activity are crude, but the errors are hardly great enough to account for apparent discrepancies of this magnitude Fat and nitrogen balances were not done on these patients, but it is unlikely that losses of these substances in the fæces were great We must for the time being admit that there are a few patients whose low weight we cannot explain

Reduced capacity and postcibal symptoms are clearly important causes of reduced intake, but they are not the only ones It is generally believed that appetite is usually unimpaired by gastrectomy, but the increase in appetite produced by iproniazid and methyltestosterone suggests that anorexia may be commoner than is recognised by either surgeons or patients

Dietary management increases weight by making the best use of the patient's reduced capacity, and iproniazid by increasing his appetite It is not quite clear how methyltestosterone exerts its effect. It is known to promote protein anabolism, but this will not increase weight unless at the same time the intake of food is enhanced, the loss of food derivatives in the fæces is reduced, the metabolic rate is lowered, or excessive fluid is retained in the body 4 of our patients admitted eating more food while taking methyltestosterone, but we have no information on the other possible factors

Although appreciable weight-gains were achieved in several patients, none regained his standard or health weight The best method of increasing weight after gastrectomy remains to be discovered Dietary supervision is difficult, but effective Methyltestosterone is not effective in all patients, and is undesirable because of its possible side-effects We have not yet tried the effects of the so-called "non-virilising" androgens Iproniazid is effective in some, but not in all, and is free from complications in the doses which we have used Possibly other methods will be found, different methods will help different patients, and combinations of remedies will prove more effective than one alone † We do not know how many, if any, underweight patients can be induced to regain their standard or health weights, but our aim should be to help every patient to do so

Summary

A relation was found between the weight changes before and after gastrectomy In general those who lose weight before operation gain weight afterwards, while those who maintain a steady weight before operation lose weight afterwards

Those who are much underweight usually eat too little food

Postcibal symptoms are often associated with low weight

Patients who are underweight after partial gastrectomy gain an average of 4 lb in eight weeks when treated with dietary supervision, methyltestosterone, or iproniazid Dummy tablets, intramuscular iron, and vitamin B_{12} have no effect

Addendum

A further group of 9 underweight male patients was treated with a combination of dietary management and methyltestosterone (50 mg per day)

The mean weight gain at eight weeks in this group was 6 2 lb (S D ± 2 3), which was greater than the gain in any other group (If this group is compared with the "diet" and "methyltestosterone" groups together, t(25 D F)= 2 07—0 05 > P > 0 02)

We are grateful to Sister D I Poole and Sister F M Clarke of the department of surgery, Queen's University, for help with the clinical trial, Mrs P Kemp for secretarial work connected with the trial and for typing the script, Prof H W Rodgers for permission to investigate and treat his patients, Prof C A Wells for his interest and encouragement in the work that was done in his department in Liverpool, Dr E A Cheeseman, reader in medical statistics, and Mr J D Merrett, both of the department of social medicine, Queen's University, Belfast, for their help with fig 1, Miss M Lawlor and Miss E M Wauchob of the dietetic department, Royal Victoria Hospital, for their help, Dr L Goldberg of Benger Laboratories Ltd for supplies of 'Imferon', Dr E W Tapley of Roussel Laboratories Ltd for supplies of methyltestosterone, and Dr J A Marks, of Roche Products Ltd for supplies of iproniazid

ACTIVE chronic hepatitis (Saint et al 1953) is a relapsing inflammatory process believed to be a sequel to overt or subclinical viral hepatitis The liver at necropsy presents the features of so-called postnecrotic cirrhosis In some cases the lupus-erythematosus (L E) cell test and auto-immune complement-fixation (A I C F) test may be positive (Joske and King 1955, Gajdusek 1957) Perpetuation of the hepatitis may depend on an immunological disorder and may be favourably modified by cortisone (Mackay et al 1956) Previous results of the treatment of active chronic hepatitis with cortisone have also suggested that clinical and biochemical improvement takes place (Sborov et al 1955, Last 1957), but the mode of action of cortisone in active chronic hepatitis has remained obscure

In the absence of other visceral disease the level of glutamic oxaloacetic transaminase in the plasma (PGOT) provides a sensitive index of the degree of liver-cell necrosis (Wróblewski and LaDue 1955)

We present here the results of cortisone therapy in ten patients with chronic liver disease of various types in whom the rate of destruction of the hepatic cells was followed by serial PGOT estimations

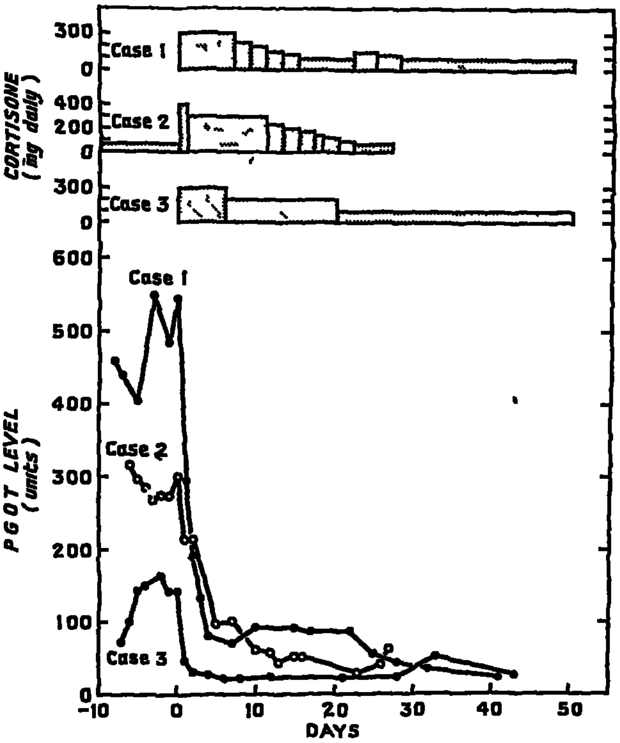

Fig 1—Effect of cortisone in relapses of active chronic hepatitis in cases 1-3 Note pronounced fall of PGOT level coinciding with cortisone therapy

Methods

Serial PGOT activity was estimated by a modification (E N O'Brien and A J Goble unpublished) of the spectrophotometric method of Karmen (Karmen et al 1954) The normal range for this method is 5–28 units The AICF test was made by the method of Gajdusek (1957) Other laboratory methods have been described previously (Saint et al 1953, Mackay et al 1956)

After pre-treatment PGOT activity had been determined for several days, oral treatment with cortisone was begun, usually in the dosage of 300 mg daily, or with the equivalent dosage of prednisolone The dosage was subsequently adjusted to a maintenance dosage of 75–125 mg of cortisone daily

Results

Five patients had active chronic hepatitis In three of these (cases 1–3) with greatly raised PGOT levels there was a precipitate fall in PGOT levels during the first 48 hours of cortisone treatment, followed by a gradual fall to normal levels over the next 2–4 weeks (fig 1)

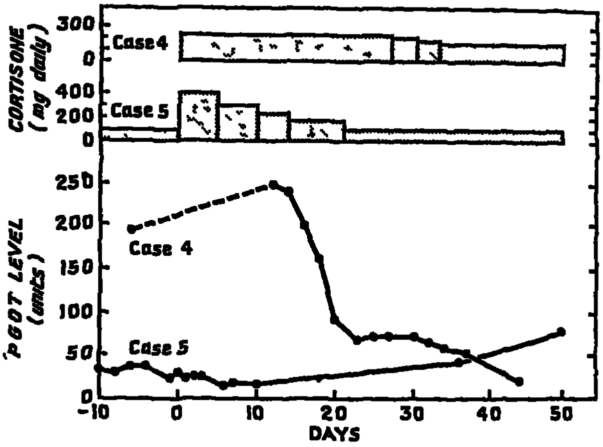

Fig 2—Effect of cortisone in active chronic hepatitis Case 4: note delayed fall of PGOT level (initial data were incomplete) Case 5: note slight fall of PGOT level following increased dosage of cortisone

In case 4 pre-treatment PGOT levels were also greatly raised, but cortisone produced a more gradual fall to normal levels (fig 2) In case 5 the pre-treatment level was only moderately raised, it fell slightly when the cortisone dosage was increased from 100 to 400 mg daily (fig 2)

Of the remaining five cases case 6 had hæmochromatosis with liver failure, case 7 had hepatic necrosis and regeneration in association with a carcinoma of the hepatic duct and portal-vein thrombosis, case 8 had subacute hepatitis of uncertain type, and cases 9 and 10 had chronic nutritional hepatitis In these cases there was no significant fall in PGOT levels with cortisone treatment (figs 3 and 4) However, in cases 8–10 the pre-treatment PGOT levels were not so high

Other pathological and biochemical data are set out in the accompanying table

The addition of 2 5 mg of hydrocortisone succinate to the 3 ml PGOT test system did not influence PGOT activity Cortisone caused no change in PGOT activity in two patients with disseminated lupus erythematosus without liver involvement and in a healthy person

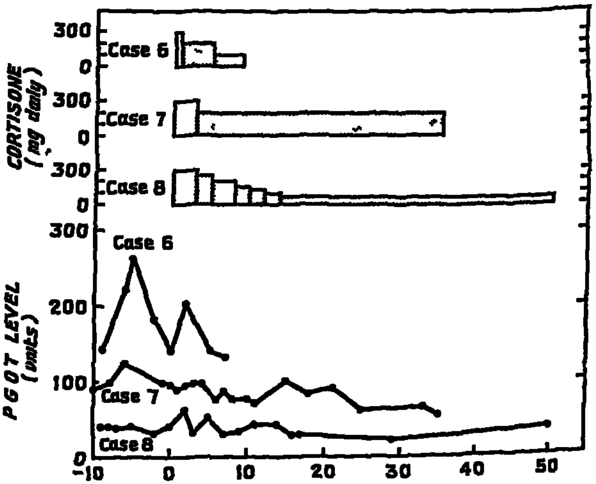

Fig 3—Case 6 (hæmochromatosis and hepatoma), case 7 (cancer of hepatic duct with obstruction), and case 8 (probably ischæmic necrosis of liver) note PGOT levels uninfluenced by cortisone treatment

Case-reports

Case 1.—A housewife, aged 29, was first seen in May, 1956, for diarrhœa which had lasted three months Ulcerative colitis was diagnosed by sigmoidoscopy In October, 1956, she had severe hepatitis, from which she recovered slowly An attack of acute appendicitis in March, 1957, was followed by diffuse suppurative peritonitis requiring drainage In September, 1957, she developed polyarthritis, followed in five days by jaundice

On examination she had many spider nævi, her liver was palpable 2 cm below the costal margin, her spleen was impalpable, and the small joints of her hands were swollen The biochemical results indicated active chronic hepatitis, which was confirmed by liver biopsy immediately before treatment

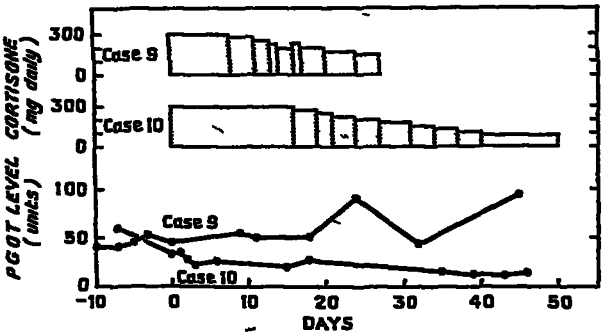

Fig 4—Cases 9 and 10 (nutritional hepatitis) initial P G O T, levels were less highly raised, despite pronounced cell necrosis, no significant change in P G O T levels took place with cortisone treatment.

Cortisone therapy was followed by immediate subjective improvement, a fall in temperature, and a steep fall in the P G O T level (fig 1) The jaundice faded. The patient was discharged well after 4 weeks' treatment, taking cortisone 75 mg daily The improvement in biochemical findings is shown in fig 5 A second liver biopsy, 4 weeks after the start of cortisone therapy, showed decreased necrosis, regenerative activity of the liver-cells, and a slight decrease in inflammatory infiltration.

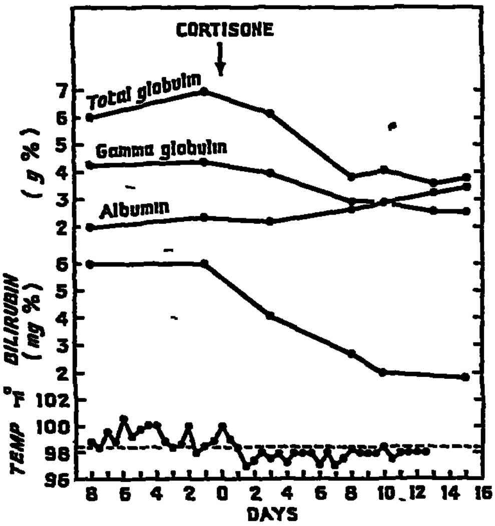

Fig 5—Biochemical findings and temperature chart in case 1 showing improvement during cortisone treatment.

Case 2.—A male clerk, aged 19, had two months' history of malaise, abdominal discomfort, and mild jaundice when seen in December, 1953 Liver-function tests and liver biopsy confirmed the diagnosis of active chronic hepatitis Cortisone therapy produced subjective improvement, although liver-function tests did not alter significantly In October, 1956, splenectomy was done for thrombocytopenic purpura with considerable benefit In October, 1957, the patient presented with two weeks' history of weakness, anorexia, and jaundice, which had begun after he had stopped taking cortisone (75 mg daily) for 3 days

On examination he had moderate jaundice, numerous spider nævi, slight hepatomegaly, and hepatic fœtor Biochemical tests and liver biopsy revealed severe liver damage The

† Zero time denotes start of cortisone therapy

patient improved on cortisone 300 mg daily, and P G O T levels fell rapidly (fig 1)

Case 3 —A Hungarian refugee, aged 47, had intermittent epigastric pain, recurrent pain and swelling of the hands and knees, and pale stools and dark urine for several months She had undergone thyroidectomy for thyrotoxicosis in 1949, and cholecystectomy in 1955, when cirrhosis of the liver was observed She had never been jaundiced

On examination she was obese, with numerous spider nævi Her liver was just palpable and tender She had no splenomegaly Biochemical tests and liver biopsy suggested active chronic hepatitis There was 45% bromsulphalein retention She improved with rest in bed but relapsed three months later with lassitude and arthralgia

Cortisone therapy —Within 36 hours of the start of cortisone therapy there was a dramatic fall in the P G O T level from 140 units to a normal value (fig 1), and her general condition improved rapidly

Case 4 —A housewife, aged 57, had six weeks' history of anorexia, nausea and vomiting, pruritus, and deepening jaundice She had been jaundiced 17 years previously

On examination she was jaundiced, and her tender liver was just palpable Biochemical tests suggested severe hepatitis Cholecystography revealed a gallstone Liver biopsy showed active chronic hepatitis Initial P G O T data were incomplete, steroid therapy was associated with an apparently delayed but sustained fall of the P G O T level to normal values (fig 2) Clinical improvement has been maintained

Case 5 —A housewife, aged 40, presented in October, 1954, with active chronic hepatitis and arthralgia (Joske and King 1955, Mackay et al 1956, case 7) She has been maintained in reasonable health on cortisone 100 mg daily since January, 1955

Case 6 —An ordnance worker and storeman, aged 62, had anorexia and tiredness for nine months, diarrhœa for four months, and melæna for one month

On examination he was deeply jaundiced, his skin was grey, he had gross ascites, and the left lobe of his liver was palpable Biochemical tests indicated hepatocellular damage The glucose-tolerance curve was that of diabetes mellitus P G O T levels were considerably raised He was given prednisolone but died in hepatic coma precipitated by massive gastrointestinal hæmorrhage No significant change in P G O T activity was observed (fig 3) Necropsy revealed multiple gastric erosions and hæmochromatosis of the liver with necrotic nodules of hepatoma

Case 7 —A Maltese cleaner, aged 49, had jaundice for two weeks He had undergone two abdominal operations seven years previously for a " tumour ", but had since been well

On examination he had deep jaundice and a few small spider nævi, and 5 cm of liver and 2 cm of spleen were palpable Biochemical tests suggested hepatocellar damage, and liver biopsy showed liver-cell necrosis and nodular regeneration The patient's condition deteriorated over the next three months, and intractable ascites developed

Cortisone produced subjective improvement but no significant alteration in liver-function tests or in transaminase levels (fig 3) This led to a reconsideration of the diagnosis, and laparotomy was done An operative cholangiogram showed obstruction to the left hepatic duct Subsequent necropsy revealed carcinoma of the left hepatic duct, portal-vein thrombosis, hepatic necrosis, and nodular regeneration of the right lobe of the liver

Case 8 —For six weeks a Latvian waitress, aged 57, had had anorexia, malaise, nausea, and pain under her right costal margin, followed by jaundice

On examination she was deeply jaundiced, and her liver was enlarged to 5 cm below the costal margin Ascites and peripheral œdema subsequently developed Biochemical tests suggested hepatitis, but liver biopsy showed mainly granulation tissue and a few surviving liver-cells The diagnosis was thought to be ischæmic necrosis of the liver, but subacute hepatitis was also considered Cortisone produced subjective improvement and a gradual but unsustained fall in the P G O T level (fig 3)

Case 9 —An alcoholic housewife, aged 36, was admitted to hospital in a confused and irrational condition, which progressed to hepatic coma

On examination she was jaundiced and anæmic, with spider nævi and considerable hepatosplenomegaly Liver biopsy showed severe advanced nutritional hepatitis Prednisolone was given without significant effect on transaminase levels (fig 4), although gradual clinical and biochemical improvement took place

Case 10 —An alcoholic male, aged 36, had anorexia and vomiting attacks for nine months

On examination he had exfoliative dermatitis, gross ascites, and an enlarged liver The biochemical tests were in accord with the liver-biopsy diagnosis of chronic nutritional hepatitis He developed liver coma Prednisone and supportive treatment were given, and were followed by slow improvement

Discussion

The glutamic oxaloacetic-transaminase level in plasma and in serum is raised in patients with hepatic-cell necrosis from any cause (Wroblewski and LaDue 1955) The enzyme is liberated from damaged liver-cells, so the P G O T level represents the degree of liver-cell necrosis Therefore, by serial estimations of P G O T in chronic hepatitis, it is possible to follow the rate of hepatic-cell necrosis and to assess the effects of treatment by cortisone

Five of the ten patients studied had active chronic hepatitis In cases 1–3 the P G O T level fell dramatically from previously high values within 48 hours of the start of cortisone treatment (fig 1), this was followed by a more gradual fall to normal values, with steady clinical and biochemical improvement In case 4 the initial fall was more gradual, but the same general pattern was followed (fig 2) In case 5 an equivocal fall of the P G O T level followed a fourfold increase in the dosage of cortisone (fig 2) It may be significant that, at some stage in the disease, the L E -cell test was positive in four, and the A I C F test in three, of these cases On clinical and biopsy evidence, however, they were indistinguishable from active chronic hepatitis of the post-viral type

Five cases with hepatic-cell necrosis from other causes behaved differently (figs 3 and 4) Case 6, with hæmochromatosis, did not respond to cortisone, P G O T levels remaining high, and he died in liver failure Case 7 was initially believed to have active chronic hepatitis but did not respond to cortisone treatment Laparotomy and subsequent necropsy disclosed biliary obstruction due to a hepatic-duct carcinoma, and portal-vein thrombosis with hepatic necrosis and nodular regeneration in the right lobe In case 8 the diagnosis remained uncertain Cases 9 and 10, with nutritional (alcoholic) hepatitis, both had advanced active liver disease and an episode of hepatic coma, yet the P G O T levels were only moderately raised, and were not significantly altered by cortisone therapy

Thus, judged by transaminase levels, cortisone *did not* inhibit liver-cell necrosis associated with hæmochromatosis, biliary obstruction, and ischæmia and alcoholic malnutrition, but rapidly did so in four cases of active chronic hepatitis It is uncertain which cases of active chronic hepatitis will prove to be cortisone-sensitive, there may be a poor response in late cases with well-established cirrhosis

The exact nature of the liver-damaging process in active chronic hepatitis is unknown We believe that the sensitivity of this process to cortisone therapy is more consistent with an immunological concept of hepatocellular injury than with concepts of damage resulting either from continuing viral activity in the liver or from circulatory derangements associated with regenerating nodules An analogy may possibly be drawn with the effect of cortisone in acquired hæmolytic anæmia, wherein cortisone inhibits the damaging effects of an antigen-antibody reaction at cellular level, cortisone may operate in a somewhat similar fashion in these acute relapses of chronic hepatitis

This limited study supports the use of cortisone in acute exacerbations of active chronic hepatitis but sheds no light on the effect of cortisone on the ultimate outcome of the disease It could well be argued, however, that rapid control of the necrotic process might lessen hepatic scarring and disorganisation

Summary

In ten patients with chronic liver disease the rate of liver-cell necrosis was followed by serial estimations of glutamic oxaloacetic-transaminase activity in the plasma before and during cortisone treatment.

In four of five patients with active chronic hepatitis a pronounced fall in transaminase levels coincided with cortisone treatment

In five patients with chronic liver disease of different ætiology there was no significant fall in transaminase with cortisone treatment

This limited study indicates that cortisone reduced the rate of liver-cell necrosis in relapses of active chronic hepatitis, thus favourably influencing the course of the disease

We wish to thank Miss B Paterson for assistance with transaminase estimations, Prof R R H Lovell for generously providing laboratory facilities in the University Department of Medicine at the Royal Melbourne Hospital, Dr L I Taft for histological interpretations, Dr S Weiden for biochemical estimations, and Dr K Fairley, Dr T Hurley, Dr L Rothstadt, and Dr W E King for kindly referring patients

LARGELY as a result of the work of Wróblewski and his colleagues (Karmen et al. 1955, Mason and Wroblewski 1957) determination of serum glutamic-oxaloacetic transaminase (S G O T) activity is widely used as a diagnostic test in acute myocardial infarction and diseases of the liver The liver has been shown to be the main source of serum glutamic-pyruvic transaminase (S G P T), for this enzyme is found in relatively high concentration in the liver In various forms of liver disease S G P T activity is often above normal levels, whereas in myocardial infarction it is not significantly raised unless the liver is also involved (Wroblewski and LaDue 1956, Chinsky et al 1957)

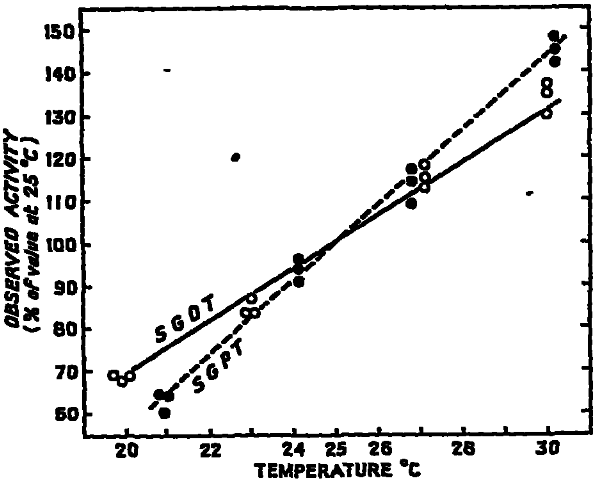

Fig 1—Effect of temperature on S G O T and S G P T activities

The work described here was done to find out if the determination of serum-transaminase activity should be recommended for inclusion in the routine liver-function tests in a hospital laboratory

More than 1000 determinations were done on 226 patients and 50 healthy controls The patients included 66 with ulcerative colitis, of whom 10 had hepatic complications, 13 with obstructive jaundice, 15 with infective hepatitis, 27 with either cirrhosis or chronic hepatitis, 27 with hepatic metastases, 11 with cholecystitis, 35 with miscellaneous diseases of the intestinal tract not involving the liver, and 25 without organic disease

While this paper was being prepared, Madson et al (1958) reported S G O T determinations in various hepatic disorders

Methods

All the results summarised here were obtained by the methods of Karmen et al (1955) for S G O T or that of Wroblewski and LaDue (1956) for S G P T with a 'Unicam S P 500' spectrophotometer In these procedures the transaminase system is coupled with a second enzymic reaction involving the oxidation of the reduced form of diphosphopyridine nucleotide (D P N H)

Temperature—Though the recommended concentrations of reagents and enzymes and the general procedure were satisfactory, we found that fluctuations of temperature caused considerable variations in the results obtained in both series In the original description of the method estimations were made at an unspecified room temperature It was impracticable to apply thermostatic control to the cuvettes in the instrument at our disposal, but our aim was achieved simply by taking the temperature of the contents of the cuvette immediately after the final reading of the optical density The room temperature was varied between 20° C and 30° C, and a series of determinations were made on the same sera Fig 1 shows the effect of temperature on the observed S G O T and S G P T activities Steinberg et al (1956) have described a temperature-correction curve for S G O T with which our results are in close agreement All the results described here were adjusted to 25° C

Blanks—When the sample of serum was clear, we found it possible to dispense with a serum-reagent blank (omitting D P N H), and to use instead a solution of 0·0005*N* K_2Cr O in accordance with the recommendation of Sobel et al (1956) When the dichromate blank was used with a lipæmic serum, however, erroneously high values, due to the separation of particles of serum during the measurement of optical density, were sometimes obtained In these cases a full serum and reagent blank was obligatory Usually this was unnecessary, and a considerable saving of serum, time, and reagents was thus effected

Reproducibility—Numerous replicate experiments showed the reproducibility of the method (including correction of temperature) to be within 10% of the mean, but in the normal and equivocal ranges the variation was within 5% of the mean

Hæmolysis—Since blood hæmolysates may contain up to fifteen times the serum-transaminase activity (Karmen et al 1955) hæmolysis of specimens should be avoided, and serum should be separated without undue delay In our experience minor degrees of hæmolysis did not significantly affect the results These enzymes were surprisingly stable, and the activities of sera did not deteriorate on storage at −18° for several weeks

Colorimetric methods—We also examined the colorimetric methods of Cabaud et al (1956), Wroblewski and Cabaud (1957), and Reitman and Frankel (1957), but we prefer the spectrophotometric procedures because they are less laborious, more reproducible in the equivocal ranges, and require less sera High activities were easily detectable by all four methods

Paper electrophoresis—Serum (80 μl) was applied to Whatman No 3MM filter paper previously ruled into serially numbered 1-cm strips The paper was saturated with barbitone buffer (pH 8 6, μ 0 05) and subjected to electrophoresis by the hanging-strip method at a potential difference of 110 V for fifteen hours While still wet the paper was cut into 1 cm strips, each of which was immersed in 2 ml of 0 067*M* phosphate buffer of pH 7 4 Each strip was found by experiment to contain 0 3 ml of barbitone buffer, thus the total dilution was 2 3 ml in each case SGOT and SGPT activities were determined on 0 5 ml aliquots of each eluate, blank estimations being made on similar strips cut from the same paper beyond the zones containing protein Duplicate electrophoregrams similarly divided into 1 cm strips were run at the same time, these were dried and stained with light-green in the usual way to show the positions of the protein bands

Results

ELECTROPHORETIC MOBILITIES OF SGOT AND SGPT

The electrophoretic mobility of SGOT determined by the method described above was intermediate between that of α_2-globulin and that of β-globulin The results obtained with serum from a typical case of infective hepatitis are shown in fig 2 Similar results were obtained with serum from other hepatitis cases and from patients with obstructive jaundice Owing to the relatively low activity of normal serum it was impossible to apply this method to the serum-transaminases of healthy people, but a comparison was made of the mobilities of SGOT from cases of liver disease and myocardial infarction, they were identical Since our electrophoretic studies were completed our attention has been drawn to a report by Wroblewski (1957) in which a similar conclusion was reached by the moving-boundary method, but no experimental details were given

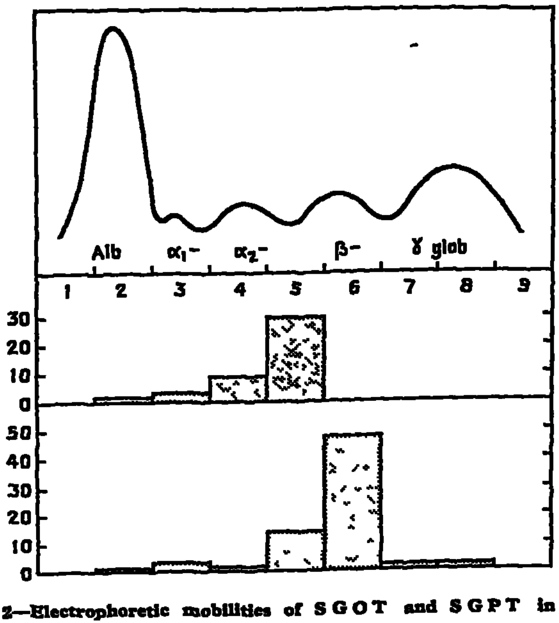

Fig 2—Electrophoretic mobilities of SGOT and SGPT in infective hepatitis

SERUM-TRANSAMINASE ACTIVITIES IN PEOPLE WITHOUT HEPATIC OR CARDIAC DISEASE

Condition	SGOT (units per ml)			SGPT (units per ml)		
	No of persons	Mean ± S D	Range	No of persons	Mean ± S D	Range
Healthy controls	50	19 ± 6	11–38	50	16 ± 5	7–26
Patients without organic disease	25	19 ± 6	8–32	—	—	—
Chronic cholecystitis (non-icteric)	11	15 ± 6	8–27	7	11 ± 5	5–22
Ulcerative colitis without hepatic complications	56	18 ± 7	7–33	22	11 ± 5	5–22
Miscellaneous intestinal diseases not involving the liver*	35	18 ± 7	9–37	20	13 ± 4	4–20

*These included 5 cases of peptic ulcer, 5 of steatorrhœa, 2 of argentaffinoma, 5 of gastric carcinoma, 3 of rectal carcinoma, 5 of carcinoma of the colon, 8 of diverticulitis, and 2 of regional ileitis

SERUM-TRANSAMINASE ACTIVITIES

Normal Values

SGOT and SGPT activities were determined in 50 healthy adults aged 19–50 No significant difference was found between the values given by males and females or by different age-groups The results are summarised in the accompanying table with those obtained in hospital patients with conditions unlikely to affect transaminase levels These figures are somewhat lower than those reported by Wroblewski and his colleagues, who obtained means of 22±7 SGOT units per ml and (at 23° C) 16±9 SGPT units per ml If the latter is adjusted to 25° C it becomes 20±11 units per ml

We suggest that values over 40 SGOT units per ml and 30 SGPT units per ml be regarded as abnormal, provided that the results have been corrected to 25° C

Serum-Transaminase in Liver Disease

A summary of the results obtained is illustrated diagrammatically in fig 3, which shows that, in four main categories of liver disease, transaminase activities may sometimes be of considerable diagnostic importance

Acute hepatitis—Very high levels of SGOT activity (sometimes higher than 2000 units per ml) were observed in acute infective hepatitis, the highest figures being obtained at the onset of jaundice Fig 4 shows the variation in transaminase activity during the course of the disease in 2 cases—one a typical acute infective hepatitis of short duration, and the other a more prolonged and more severe attack The time during which the enzyme activities remained raised varied according to the severity of the disease, from twelve days after the onset of jaundice in one of the cases illustrated in fig 4 to more than thirty-four days in the other The SGOT level was initially higher than the SGPT level in 5 of the 8 cases seen within three days of the development of jaundice, but it fell more rapidly, with the result that, in several cases, the SGPT level was higher at some stage during recovery

1 subicteric case of infective hepatitis showed SGOT 110 units per ml and SGPT 109 units per ml after seven days' malaise

patients with glandular-fever hepatitis with positive l-Bunnell tests were also studied 1 had S G O T units per ml and S G P T 140 units per ml four days r the onset of symptoms, but four days later these els had fallen to 44 and 46 units per ml respectively, 2nd patient's serum, collected soon after the beging of the illness, contained S G O T ·191 units per ml. S G P T 221 units per ml, and four days later these els had risen to 428 and 358 units per ml respectively, the patient had developed jaundice, and the 3rd ient's serum after a week's illness contained S G O T units per ml. and S G P T 242 units per ml A case glandular fever without hepatitis, however, had nor-l transaminase levels

Obstructive jaundice—Of the 13 cases investigated ad obstruction due to carcinoma of the pancreas or of common bileduct and 6 had cholelithiasis All wed raised S G O T levels, mostly 80-200 units per , and in 10 of 12 of these the S G P T activity was also reased, but in only 1 case did it exceed the S G O T lues In contrast with our experience in the hepatitis ses, the transaminase levels remained high until the struction was relieved by surgical intervention, after ich they returned to normal within a week

One of the cases studied showed spontaneous rises and ls of serum-transaminase levels, which, subsequent estigations suggested, were probably caused by the ssage of gallstones

Cirrhosis and chronic hepatitis—These cases were very iable, ranging from well-compensated patients with all fibrotic livers to a patient with hepatic coma The G O T level was raised in 20 and the S G P T in 11 27 cases, the latter exceeding the S G O T in only case

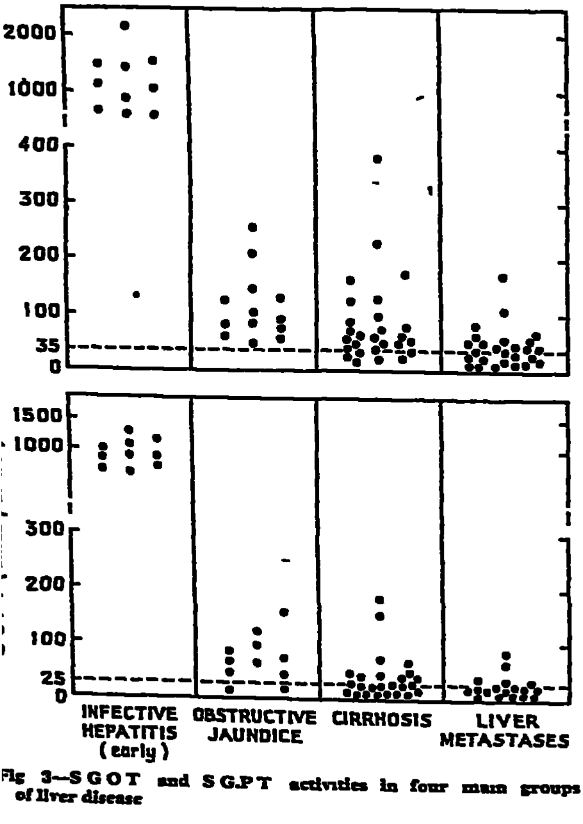

Fig 3—S G O T and S G.P T activities in four main groups of liver disease

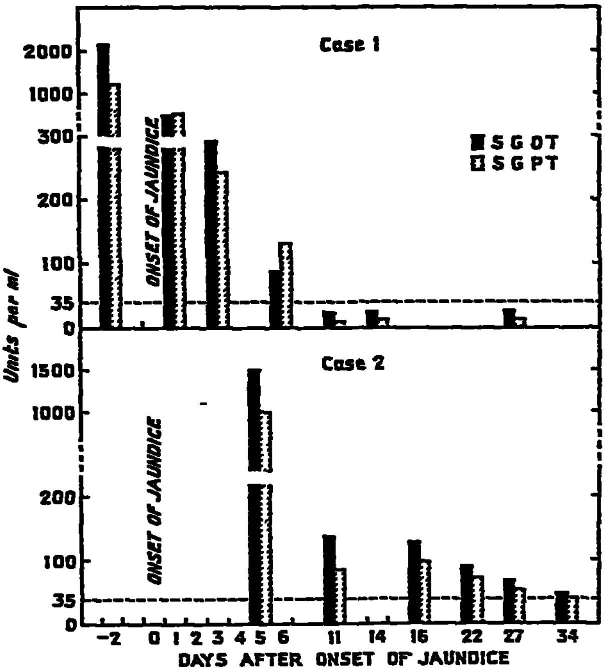

Fig 4—S G O T and S G.P T activities in 2 patients with infective hepatitis.

The raised S G O T values were mostly 40–120 units per ml, whereas the S G P T values only slightly exceeded the normal range The two very high values (fig 3) arose in 2 cases with evidence of acute liver-cell necrosis, one at biopsy and the other at necropsy following death from hepatic coma

Liver metastases—15 of 27 cases showed raised S G O T values and 5 out of 18 raised S G.P T values In each case the raised S G.P T value was associated with a high S G O T value. The highest values (fig 3) were obtained in a case of primary carcinoma of the breast which at necropsy showed massive liver metastases The other S G O T value exceeding 100 units per ml was in a case of prostatic carcinoma in which hepatic secondaries were accompanied by considerable hepatic necrosis In the remaining cases the raised S G O T values were 40–70 units per ml, the S G P T values were usually normal

Ulcerative colitis—The transaminase levels closely paralleled the incidence of concurrent liver disease in this series of patients, for in all the cases in which high values were obtained either clinical or pathological evidence of liver disease was found or other liver-function tests were abnormal In 56 cases without evidence of liver complications the transaminase activities were normal, but in the remaining 10 the S G O T level was raised in 9 and the S G P.T in 3

Both patients with the highest values (120 and 167 S G O T units per ml and 180 and 68 S G P T units per ml) may possibly have chronic hepatitis, but this diagnosis has not yet been confirmed In the remaining cases the S G O T level was only slightly raised (40–60 units per ml)

Toxic hepatitis—3 cases of toxic jaundice were studied 1 of these, which arose as a result of an unsuccessful attempt at suicide by swallowing "safety-match" heads, showed serum-transaminase activities of S G O T 69 units per ml and S G P T 129 units per ml Similar high levels were maintained for fourteen days The 2 other cases were of chlorpromazine jaundice, in which the following figures were obtained initially SGOT 82 and 137 units per ml and SGPT 46 and 204 units per ml We did not have the opportunity of studying the effect of carbon-tetrachloride poisoning in man, but in the serum of rabbits previously treated with this hepatotoxic agent (kindly provided by Dr D Marrack) activities up to 6000 SGOT units per ml and 2000 SGPT units per ml were obtained

Liver infarction—A sample of serum taken from a patient with a liver infarction due to malignant involvement of the right hepatic artery (confirmed at necropsy) gave transaminase activities of SGOT 250 and SGPT 372 units per ml Bilirubin, alkaline phosphatase, and a battery of flocculation tests were all normal

Partial hepatectomy—A case of isolated hepatic secondaries was treated by surgical removal of the involved lobe An immediate postoperative rise to SGOT 800 units per ml and SGPT 800 units per ml was followed by a rapid fall to SGOT 36 and SGPT 57 units per ml by the sixth day after operation As in some of the infective hepatitis cases, the SGPT activity returned to normal at a somewhat slower rate than the SGOT

Discussion

The value of SGOT determinations in myocardial infarction may be regarded as established, for several workers have confirmed the transient rise which takes place during the day or two following the episode (Shabetai et al 1957, Chinsky and Sherry 1957) Wroblewski and LaDue (1956) showed that, in this condition, the SGPT activity was not significantly raised, thus providing a means of distinguishing between the transaminases of liver and heart This finding has been confirmed in this laboratory The SGOT activity was increased in each of 20 cases of myocardial infarction but, although the SGPT level occasionally showed a transient rise and fall, especially in the patients with the more extensive infarcts, it never rose above 40–50 units per ml except in the presence of probable liver damage Further details of these tests are to be published elsewhere

We examined the possibility that these enzymes were different entities by investigating their behaviour on paper electrophoresis We found that SGOT and SGPT have different electrophoretic mobilities and must therefore be different substances, whereas the mobility of the SGOT derived from the heart was identical with that of the enzyme released by the liver It therefore seems probable that liver and heart release the same SGOT According to our experiments the actions of these enzymes were specific, because the SGOT isolated by paper electrophoresis could not utilise alanine as donor molecule Similarly SGPT isolated by the same method had no effect on aspartic acid There is thus no possibility that SGOT and SGPT are one and the same enzyme able to transfer amino groups from various aminoacids

The highest levels of SGOT and SGPT in the serum were found in cases of acute hepatocellular damage, whatever the cause, be it viral infection, chemical poisoning, or physical trauma Activities of SGOT 12,300 units per ml have been reported in carbon-tetrachloride poisoning (Wroblewski et al 1956), a condition we have studied only in rabbits Very high values (over 1000 units per ml) occurred in infective hepatitis at the onset of jaundice, when the SGOT level was usually the higher During later stages the SGOT level was often exceeded by the SGPT level, and in consequence the latter was useful when serum was not available until the fourth or fifth day of jaundice Both tests were valuable in providing an index of severity of the disease The high values were a constant finding in the early stages, whereas in some cases the alkaline-phosphatase and flocculation tests remained normal throughout As an example of the effects of physical trauma may be cited the case treated by partial hepatectomy in which serum-transaminase activities approaching those of the infective-hepatitis range were observed No change was detected in the result of any other liver-function test

Moderately raised levels (80–500 units per ml) were found in various conditions, some of which—e g, glandular-fever hepatitis and chlorpromazine jaundice—were easily differentiated Values of 80–200 units per ml are characteristic of obstructive jaundice and correlated well with the alkaline phosphatase Since such increased activity occurs in obstructive jaundice, probably one of the physiological functions of the liver is to control the circulating levels by excreting these enzymes into the bile in the same way as alkaline phosphatase Both enzymes have been demonstrated in bile from the common bileduct as well as in bile from the gallbladder (Pryse-Davies, unpublished)

Raised values up to SGOT 80 units per ml were difficult to interpret without evidence from other sources They often occurred in cirrhosis and liver metastases, often accompanied by high alkaline-phosphatase activity in the absence of a raised serum-bilirubin level Variations occurred in both these groups, and levels over 100 units per ml were obtained in the presence of hepatic necrosis In well-compensated cases of cirrhosis enzyme activities were either in the normal range or only slightly above SGPT activity was often normal in these two groups, especially in liver metastases, and consequently was not of much diagnostic value in these conditions

The value of SGPT determinations, however, was well illustrated in a patient suspected of myocardial infarction The SGOT values fell from 202 to 146 units per ml over three days, and then, after the patient had experienced a second painful episode, rose to 256 units per ml, thereafter falling to normal values However, these fluctuations were accompanied by similar changes in the SGPT values, suggesting the liver rather than the heart as the source of the SGOT Subsequently, at cholecystectomy, gallstones were found while the common bileduct was patent The peaks in transaminase activities therefore appear to have been due to intermittent biliary obstruction

We conclude that transaminase determinations are useful additions to the range of liver-function tests because a proportion of cases would have gone undetected without their use Except in infective hepatitis and carbon-tetrachloride poisoning, these tests are unreliable in isolation but should be assessed with the results of other tests, especially alkaline phosphatase, serum-bilirubin, and the flocculation tests The use of both SGOT and SGPT is of value in the differentiation of cardiac and hepatic disease, but the absence of increased SGPT activity does not necessarily exclude the liver as the source of raised SGOT levels

Transaminase determinations are of value in prognosis because they enable the severity of active liver damage to be assessed both in hepatitis and in cirrhosis Thus we observed that maintenance of raised values after hepatitis indicated residual complications and delayed recovery We also found that rising levels in cases of liver metastases suggested a poor prognosis, those cases with the highest values showing at necropsy the most extensive infiltration and accompanying necrosis

The occurrence of occasional anomalous results must not be overlooked, however, for raised S G O T and S G P T values sometimes arose as a result of surgical trauma in the region of the liver and the pancreas, after extensive crush injuries involving considerable skeletal muscle damage, and during hæmolytic diseases of various types A very high value found in a case of pulmonary infarction was probably due to prolonged hypotension with consequent liver damage On the other hand, we have not so far found any increase in transaminase activities after the administration of morphine or its derivatives, as reported by Foulk and Fleisher (1957) in patients with biliary-tract disease given codeine phosphate by injection

Summary

The precision and sensitivity of the spectrophotometric method of determining serum glutamic oxaloacetic transaminase (S G O T) and glutamic pyruvic transaminase (S G P T) has been improved by the application of temperature corrections

A study of 50 healthy people and 127 patients in whom no rise in transaminase levels was expected led to the conclusion that values exceeding S G O T 40 and S G P T 30 units per ml should be regarded as abnormal

In an investigation embracing a wide range of liver and gastrointestinal diseases it was confirmed that high values (over 500 units per ml) for both enzymes are characteristic of infective hepatitis and carbon-tetrachloride poisoning

Moderately raised values (100–300 units per ml) occur in obstructive jaundice, glandular-fever hepatitis, and toxic hepatitis (excluding that due to carbon tetrachloride)

Variable results were obtained in cirrhosis and liver metastases, but in 64% the S G O T level was raised above normal values, whereas only about 40% showed increased S G P T activity

Normal values were obtained in gastrointestinal diseases not involving the liver

S G O T showed a moderate and transient rise (up to 300 units per ml) in myocardial infarction, but in this condition the S G P T level usually remained normal

S G P T was thus of considerable value in confirming the hepatic origin of S G O T in certain cases

Used critically in conjunction with other liver-function tests, transaminase determinations were extremely useful

We wish to thank Dr W H Kelleher, Dr J H Watkin, and our clinical colleagues of the Westminster Hospital Teaching Group for sending samples of blood for investigation, and Prof N F Maclagan for helpful criticism The 'Unicam *S P 500*' spectrophotometer used throughout this work was purchased with the aid of a grant to one of us (J H W) from the Central Research Fund of the University of London

GLUCOSE AND INSULIN IN SCHIZOPHRENIA

SHEILA R LEYTON
M B Aberd
SENIOR HOUSE-OFFICER, POWICK HOSPITAL, WORCESTERSHIRE

NO-ONE has so far compared the effects of insulin hypoglycæmia and glucose with the effects of glucose alone in the treatment of schizophrenia In a small investigation, therefore, all schizophrenic patients referred to the insulin unit at Powick Hospital in 1957 were divided, by alternate selection, into two roughly similar groups, one of which received insulin hypoglycæmia and glucose, and the other glucose alone

The insulin treatment was given on customary lines, the hypoglycæmia being terminated by intravenous injection of 40–60 ml of 33% glucose followed by sugar by mouth

The fasting glucose patients were brought to the unit at the same time as the insulin ones and were given an injection of sterile water increasing in amount daily up to 3 ml While the insulin patients went into coma, the glucose patients remained in bed, and, in order to occupy them, those capable of it wrote on selected subjects At 10 30 A M during the first week of treatment the glucose patients were given the flavoured sugar drink corresponding to the insulin pre-coma stage The second week they had 20 ml of intravenous glucose each day followed by the drink, the third week 40 ml followed by a drink, and the fourth week 60 ml followed by a drink, from forty to fifty injections in all, comparable to the forty comas of the insulin patients They then had the $1^1/_2$ oz of sugar for their breakfast As much attention was paid to the glucose patients as to the insulin ones, the pulse-rates and respiration-rates being recorded every half-hour, in addition to visits and talks by the medical officer and nurses

The two groups had breakfast together and for the rest of the day were treated as one group for diet, occupational therapy, social activities, &c No sedative was given at night, and after the first week little difficulty in sleeping was experienced by any of the patients Delayed reactions were treated alike in the two groups, and in the glucose group 3 patients experienced " reactions " The average age of the insulin patients was 25 and that of the glucose patients 26 (range 15–42) The length of illness of both groups was from three months to four years

Results

The accompanying table shows the results of treatment

Treatment	Discharged	In hospital	Discharged against medical advice or did not complete course	Total
Insulin	7	6	2	15
Glucose	7	5	3	15

The results were assessed by whether the patients were discharged from hospital or not

During the year, 30 patients who had been diagnosed as schizophrenics by the senior staff of the hospital were treated in the department, 15 in each group Of these, 7 of each group were discharged and remain out of hospital, 6 of the insulin group who completed treatment remain in hospital, 1 discharged herself against medical advice without finishing treatment, and 1 patient was stopped treatment because of poor recoveries Of the patients who completed the glucose treatment 5 remain in hospital, and 3 left hospital against medical advice before completing the treatment

The number of cases is, clearly too small for any satisfactory statistical analysis, and all that can be said is that they show no significant (P>0 05) difference between the two groups This might not hold true for a large series

Whether there is going to be any difference in the relapse-rate between the two groups can be determined only after a considerable time

Summary

Alternate schizophrenics referred for deep insulin treatment were given either deep insulin (15 patients) or glucose only (15 patients)

No significant difference was observed in the discharge-rate of the two groups

I wish to thank Dr A M Spencer, medical superintendent, Powick Hospital, for his help and advice, and for permission to publish this paper, I am also indebted to Mr Tainton and other members of the nursing staff of the insulin unit for their valuable assistance

LUNG ABSCESS AND PNEUMONIA COMPLICATING INFLUENZA

J M Angeloni
M B Lond
MEDICAL REGISTRAR,
BROMLEY GROUP OF
HOSPITALS, KENT

G W Scott
M D Lond, M R C P
SENIOR MEDICAL REGISTRAR,
GUY'S HOSPITAL AND BROMLEY
GROUP OF HOSPITALS

Last October 41 adults were admitted to the Bromley, Farnborough, and Beckenham group of hospitals with pneumonic complications of influenza These hospitals serve a population of about a quarter of a million, among whom influenza was then epidemic Virus studies were not carried out, and the diagnosis of influenza was made on clinical grounds

13 of the patients had pre-existing chronic chest disease their ages ranged from 47 to 83 (average 63) They presented with the clinical and radiographic picture of a bronchopneumonia, developing from one to four days after the onset of influenza *Staphylococcus aureus* was cultured from the sputum in only 1 Of these patients 6 died, but the other 7 made good recoveries

28 of the patients were previously fit Their ages ranged from 13 to 68 (average 38) Symptoms of pneumonia developed from one to fourteen days after the onset of influenza In 14 patients *Staph aureus* was cultured from the sputum, and in 6 instances it was insensitive to penicillin 15 patients made an uneventful recovery, in 2 there was slow resolution associated with pleural effusion, 3 died of fulminating influenzal pneumonia, and 8 developed lung abscesses

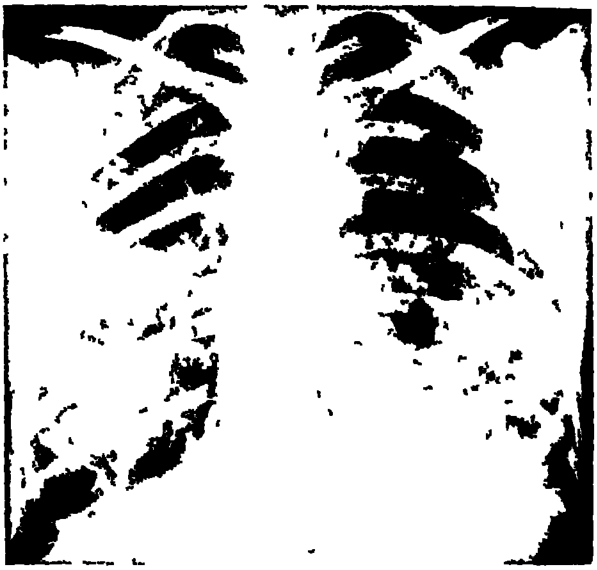

Fig 2—Case 2 Multiple staphylococcal lung abscesses following influenza

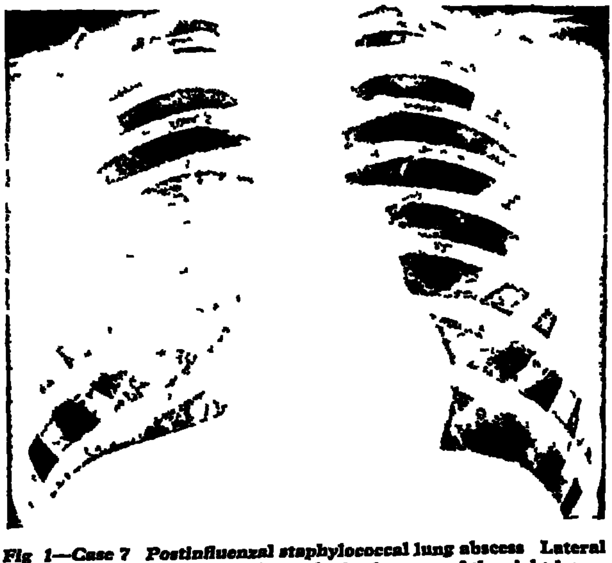

Fig 1—Case 7 Postinfluenzal staphylococcal lung abscess Lateral radiograph showed the lesion to be in the apex of the right lower lobe

As previous reports on last year's influenza epidemic in this country have not recorded lung abscess as a complication, these 8 cases are presented in greater detail

Lung Abscesses

The abscesses varied from a single lesion (fig 1) to multiple cavities throughout both lungs (fig 2) In 1 patient there was an associated empyema (fig 3) The physical signs in the chest were often inconspicuous, the commonest being impairment of percussion note with diminished air entry and râles over the affected areas

6 of the patients were extremely ill on admission, with high fever, tachycardia, dyspnœa, cyanosis, and often delirium Leucocytosis was present on admission in 3

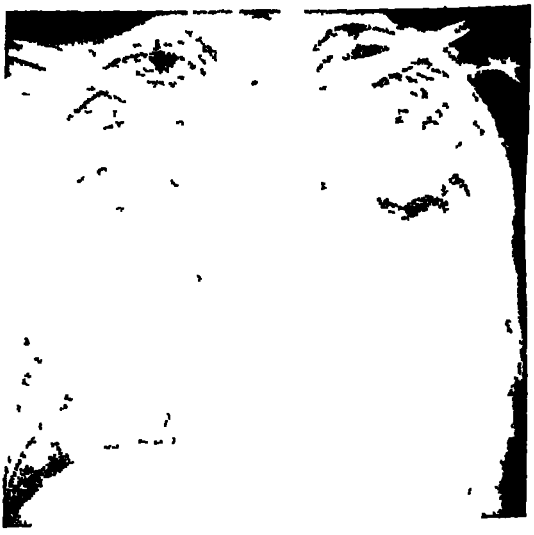

Fig 3—Case 1 Multiple abscesses in both lungs, with left-sided empyema Influenza twelve days previously

es and arose later in 3 more with the development of g abscess The highest total leucocyte-count was ,000 per c.mm.

2 patients were referred because they had failed to over satisfactorily from a postinfluenzal pneumonia ne weeks previously They did not appear gravely ill admission, and neither of them had leucocytosis

Coagulase-positive *Staph aureus* was cultured from the utum in 6 cases, and was resistant to penicillin in 3 In e patient, β-hæmolytic streptococcus was repeatedly und in sputum cultures and in another no pathogens re isolated.

Case 1—A man of 34 developed influenza and stayed in d for two days He returned to work and collapsed, with gh and left pleuritic pain He was admitted ten days later remely ill, with a temperature of 103°F, cyanosis, and delim There was impairment of percussion note with diminned air entry and râles over the whole of the left chest. The est radiograph showed multiple cavities in the left lung with pleural effusion and two cavities in the right upper lobe (fig 3) ucocytes 21,000 per c.mm (polymorphs 80%) Sputum ltures grew β-hæmolytic streptococci on several occasions peated chest aspiration produced purulent fluid which grew e same organism twice The abscesses in both lungs cleared th antibiotic treatment and postural drainage, and the npyema was drained by resection of the 11th rib and insertion a tube Five months later treatment continues for a small npyema cavity

Case 2.—A woman, aged 47, developed left pleuritic pain x days after the onset of influenza. Eight days later she was lmitted seriously ill, with temperature 103°F, pulse-rate 130 er min, and cyanosis with rapid shallow breathing She had een treated at home for three days with penicillin and tetracline. She now had impairment of percussion note and onchial breathing at both bases and bilateral pleural friction ibs Radiography showed consolidation in the middle and wer zones of both lungs with cavities in both lower lobes, the iddle lobe, and the lingula (fig 2) Leucocytes 15,000 (polyorphs 87%) Sputum culture grew *Escherichia coli* on seven ccasions Chest aspiration produced a few millilitres of opaque uid, from which coagulase-positive *Staph aureus* was grown his organism was later recovered from the sputum Treatent with antibiotics and postural drainage was continued ntil discharge from hospital eight weeks later Radiography our months after the onset showed residual scarring in the ngula and a small cystic area in the middle lobe

Case 3—A woman, aged 53, developed influenza from hich she recovered in four days Four days later she became l again with fever, cough, and right pleuritic pain She was dmitted six days later having had oral penicillin for one day espirations shallow and rapid, temperature 104°F, pulse-rate 00 per min There was diminished movement of the right hest with impaired percussion note and low-pitched bronchial reathing over the right upper chest anteriorly Radiography howed consolidation of the right upper lobe with cavitation eucocytes 17,000 per c.mm (polymorphs 74%) Repeated xamination of the sputum failed to produce pathogenic organsms The temperature settled in eight days under treatment with penicillin and streptomycin, and the cavity had closed by wenty-one days, leaving a small area of opacity

Case 4.—A district nurse, aged 49, developed symptoms of nfluenza. Two days later she was too ill to continue work and complained of right pleuritic pain. She was admitted after another two days, delirious and with temperature 103°F, pulserate 105 per min. and respirations 30 There was impairment of percussion note and diminished air entry at the right base, with râles over the whole of the right lung Radiography showed extensive consolidation throughout the right lung Ten days later there had been considerable clearing in the right lower lobe, but a cavity was seen in the right upper lobe The leucocyte-count on admission was 4500 per c.mm (polymorphs 82%), but six days later rose to 11,500 (polymorphs 80%) Sputum cultures grew coagulase-positive *Staph aureus*, insensitive to penicillin and streptomycin but sensitive to chloramphenicol and the tetracyclines Treatment was with chlortetracycline from the day of admission, because she developed a rash after the first injection of penicillin Radiography four months later showed a thin-walled cystic area at the site of the previous abscess

Case 5—A woman, aged 42, developed pleuritic pain and dyspnœa four days after the onset of influenza She was admitted that day extremely ill with cyanosis and dyspnœa, temperature 103°F, pulse-rate 130 per min. There was impairment of percussion note and diminished air entry at the left base Chest radiograph showed diffuse shadowing in the left lower lobe Leucocyte-count was 8000 per c.mm. Subsequent chest radiographs showed a lung abscess in the left lower lobe, and the leucocytes rose to 19,000 per c.mm (polymorphs 78%) Cultures of sputum grew coagulase-positive *Staph aureus*, sensitive to penicillin and other antibiotics She was treated with penicillin and postural drainage, and the cavity had closed by the eighth week

Case 6—A pregnant woman, aged 21, developed a productive cough three days after the onset of an influenza-like illness On admission she was seriously ill, with cyanosis, temperature 104°F, pulse-rate 170 per min, respirations 40 The only abnormal physical signs in the chest were scattered râles in both lung fields, but radiography showed widespread patchy consolidation Sputum cultures grew coagulase-positive *Staph aureus*, insensitive to penicillin Leucocytes 6000 per c.mm She was treated with parenteral streptomycin and penicillin, followed by oxytetracycline when the result of sputum culture was known. There was clinical and radiographic improvement until seven weeks later, when symptoms returned and there was increase in pneumonic consolidation with abscess formation in the apex of the left lower lobe Culture of sputum produced *Staph aureus* sensitive only to erythromycin and chloramphenicol Leucocytes 12,000 per c.mm (polymorphs 85%) Treatment was continued with erythromycin and postural drainage On discharge from hospital, eleven weeks after admission, a chest radiograph showed linear opacities at the site of previous lesions Her pregnancy progressed normally, and she gave birth at term to a healthy infant.

Case 7—A National Serviceman of 19 developed influenza, for which he was in another hospital for several days On return home, he still felt unwell and ran a low-grade fever He was referred to the outpatients department, where chest radiographs showed cavitation in the apex of the right lower lobe (fig 1) He was treated with penicillin intramuscularly for two weeks, followed by tetracycline for ten days Sputum culture showed coagulase-positive *Staph aureus* insensitive to penicillin but sensitive to other antibiotics Leucocyte-count was 8000 per c.mm There was progressive radiographic improvement. Three months later a thin-walled cystic area remained at the site of the previous abscess

Case 8—A woman, aged 27, developed influenza three weeks before admission Two weeks later, she started to have a productive cough and left-sided pleuritic pain She was treated at home with parenteral penicillin and 'Sigmamycin' (tetracycline and oleandomycin), but continued to run a temperature of 100–101°F Radiography at home showed consolidation of the left upper lobe with three lung abscesses On admission, she was not gravely ill but had a cough, purulent sputum, and diminished air entry over the left upper lobe Sputum culture grew coagulase-positive *Staph aureus*, sensitive to all antibiotics Leucocytes 8000 per c.mm. Under treatment with parenteral penicillin and postural drainage, fever abated in three days Three weeks later she was discharged, but subsequent radiographs have shown the persistence of thin-walled cysts in the left upper lobe

Discussion

Postinfluenzal pneumonia caused a higher mortality in patients with long-standing chest disease (6 deaths in 13 cases) than in those who were previously fit (3 deaths in 28 cases) The same high mortality is reported for postinfluenzal pneumonia in patients with cardiac disease (Giles and Shuttleworth 1957) As might be expected, bronchopneumonia developed rapidly after influenza in patients with chronic chest disease and the pathogens isolated showed little uniformity In only 1 patient was *Staph aureus* cultured from the sputum In contrast, it was striking that *Staph aureus* was isolated from 14 of the 28 patients who were previously fit In 6 instances it was resistant to penicillin In 1 of these it was resistant to erythromycin as well, in another to chloramphenicol, and in a 3rd to streptomycin It is probable that *Staph aureus* was present in several of the other patients, though not isolated Sputum cultures may have been affected by the antibiotics, often given before admission In addition, 10 of the patients had an unproductive cough on admission, and, though it became productive in five, they were by that time on full antibiotic treatment

The incidence of staphylococcal infection reported here is in keeping with previous reports on the influenza epidemic (Hers et al 1957, Jevons et al 1957, Roberts 1957) In view of the high incidence of secondary staphylococcal infection, and the statement of Gibson and Belcher (1951) that staphylococcal lung abscess commonly follows influenza, it is perhaps surprising that no such cases are included in previous clinical reports on the pulmonary complications of this epidemic (Morgan and Pickup 1958, Walker et al 1958) Of our 8 cases, *Staph aureus* was cultured from the sputum in 6 and β-hæmolytic streptococcus in 1 These patients all survived and are clinically well In 4 patients, however, thin-walled cysts remain at the sites of the previous lung abscesses in 3 there is residual scarring, and 1 patient still has a small empyema cavity The fact that lung abscess was not fatal in this series may explain its occurrence in only 4 of the 158 fatal cases of influenzal pneumonia reported by Hers et al (1957), Giles and Shuttleworth (1957), and Roberts (1957)

Fulminating influenzal pneumonia occurred in 3 patients, who all died in spite of intensive therapy Cultures taken of the lungs at necropsy gave a pure growth of coagulase-positive *Staph aureus* in 2 cases There was no leucocytosis, and 1 patient had a leucopenia This lack of constitutional response may well be a factor in the fatal outcome In contrast, obvious leucocytosis developed in 6 patients with lung abscess They were admitted in a similarly critical condition, but all survived Lung abscess formed in 3 of these patients while they were in hospital, and leucocytosis was absent until then 5 of the patients with lung abscesses had been under treatment at home for six days or more after developing pulmonary complications The high incidence of lung abscess and the paucity of physical signs suggest the need for radiographic control early in postinfluenzal pneumonia

Summary

41 cases of postinfluenzal pneumonia are reported

In the 13 patients with pre-existing chronic chest disease the mortality was higher (6 died), pneumonia had come on more quickly following influenza, and pathogens isolated by sputum culture showed little uniformity

Among the 28 patients who were previously fit, 3 died from fulminating infection and there was a high incidence of lung abscess (8 cases) *Staphylococcus aureus* was isolated in 14 cases, and was resistant to penicillin in 6 In several others it was probably present though not isolated

Leucocytosis was not seen in fulminating pneumonia but was a feature of lung abscess

We wish to thank Dr N S Plummer, Dr W S L Gilchrist, Dr K O Rawlings, and Dr D N Dobbie, for permission to publish their cases and for their helpful advice and criticism

Addendum

Since this paper was completed, a combined study group from Dundee has reported lung abscess in 5 out of 262 cases of postinfluenzal pneumonia (*Brit med J* 1958, i, 902) In addition, the Public Health Laboratory Service has reported the necropsy findings in 219 deaths from Asian influenza and found macroscopic abscesses in the lungs in 18% of the cases Lung abscess was hardly ever found apart from staphylococcal infection (*Brit med J* 1958, i, 915)

Medical Societies

SOCIETY FOR THE STUDY OF INFECTIOUS DISEASE

A COMBINED meeting with the Glasgow School of Veterinary Medicine was held in Glasgow on May 3, with Dr T ANDERSON, the president, in the chair

Leptospirosis

Dr IAN McINTYRE dealt with leptospirosis in domestic animals in Britain *Leptospira icterohæmorrhagiæ* produce a serious and often fatal disease in the dog, in pigs the infection is milder and susceptible to antibiotic therapy, and it occurs in calves occasionally *L canicola* infection is widespread in dogs and in pigs A survey of dogs in Glasgow revealed evidence of *L canicola* infection in 35–40%, with a greater prevalence in dogs than in bitches In dogs acute leptospirosis produces a high mortality from uræmia, and recovery is often followed by chronic interstitial nephritis, hypertension, and ultimate renal failure A mild form of the disease can be reproduced experimentally Antibiotic therapy is effective in the pig and the dog if the disease is not too severe

Dr G SANGSTER described a series of 23 cases of canicola fever (18 males and 5 females) admitted to Edinburgh City Hospital The majority were young adults, and familial infection occurred in two instances, at least 12 had apparently been infected from dogs, and 4 from pigs

Bovine Lung-worm

Dr W JARRETT described a method, worked out in the Glasgow School, for vaccination against bovine lung-worm It may be applicable to human helminth infections—for example, trichiniasis and schistosomiasis At first a vaccine prepared from ground-up whole worms was tried, but this reduced the take by only 50% in challenge infections, and the partial immunity set up was sometimes associated with severe eosinophilic pneumonia The method now adopted is to produce an oral vaccine of larvæ devitalised by irradiation with ^{60}Co Such larvæ are unable to progress from the lymphatic glands to the lung On experimental challenge about 99% of the larvæ were killed by the natural defences before reaching the lungs A controlled field trial on 30 calves fed on highly contaminated pastures yielded a fatality-rate of 20% in the vaccinated calves and 83% in the controls Double vaccination with 1000 irradiated larvæ followed by 1000, 2000, or 4000 gave excellent results after very severe challenge tests, and produced extremely high titres of serological antibodies

Toxoplasmosis

Mr R S F CAMPBELL said that toxoplasmosis occurred widely in man, animals generally, and birds Serological surveys in human populations in Britain and the United States have revealed that 20-50% have been infected without any sign of clinical illness In dogs a similar prevalence is found, and lesions occur particularly in the muscles and central nervous system, distemper and active toxoplasmosis often coexist. The only route of transmission definitely known is that from mother to fœtus—possibly as a result of the failure of antibodies to penetrate the fœtal blood-brain barrier In one survey the prevalence of infection was specially high in those working with animals—veterinarians, abattoir workers, rabbit handlers, and rabbit trappers Two tests are used to determine the presence of infection (1) the cytoplasm-modifying test (a dye test producing modified staining reactions), and (2) the complement-fixation test. It has been claimed that the former is not completely specific and that confusion may sometimes arise with other protozoa—e g, *Trichomonas vaginalis* Both tests are, however, used in diagnosis For therapy combined sulphonamide and pyrimethamine is recommended.

Anthrax

Dr R LAMB and Dr W M JAMIESON discussed the hazard of anthrax in those handling bone-meal A third of the bone-meal used in Britain is imported from India, Africa, or South America, and all samples of this examined were positive for *Bacillus anthracis* Yet no instance of pulmonary anthrax has been encountered, and the incidence of cutaneous anthrax is relatively low 13 cases were described—chiefly in farm workers after spraying bone-meal, and in dockers, gardeners, a nurseryman, and a veterinarian after carrying or handling it

Bovine Tuberculosis

Prof J S S INGLIS described the rapid progress in the eradication of bovine tuberculosis since 1935, when the establishment of attested herds by repeated tuberculin-testing was introduced. Within a few years many tuberculosis-free herds were built up In 1950 we passed to the next step, which was to schedule eradication areas in which warning was given that tuberculosis would be eradicated compulsorily from all herds which had not been rendered free within two or three years This has already produced "free" areas covering two-thirds of Scotland, and it is expected that by 1961 the whole of Great Britain will be "free" Nevertheless, in "free" areas about 0 1% of cattle have been reported still to give a positive tuberculin reaction, there are residual pools of infection in human beings, pigs, dogs, and cats, and there are records of infected farm workers infecting clean herds In Glasgow, whereas in 1935 10% of the milk churns proved positive for tubercle bacilli, in 1956 not a single churn was found to be infected and the meat condemned as tuberculous was only a tenth as much as that condemned for the same reason in 1935 In Scotland Certified and tuberculin-tested milk (non-pasteurised) are now the most dangerous grades, because of the risks of brucellosis, salmonellosis, &c.

Staphylococcal Infection

Dr A D T GOVAN, Dr J G P HUTCHISON, Dr MORAG TIMBURY, and Dr T S. WILSON described an outbreak of 14 cases of staphylococcal infection (5 fatal) in a Glasgow maternity unit All were of phage-type 80 In addition 4 cases of type-80 infection (2 fatal) were found among babies recently discharged Nose and throat swabs of the staff revealed a surprisingly low carriage-rate of type 80 (1%), but 3 out of 13 babies swabbed had type 80 in the nose Transmission is believed to have been from baby to baby Closure of the unit appears to be the quickest way to get rid of this infection, in this case it was all over in six weeks The type-80 strain was resistant to penicillin and the tetracyclines, but not to chloramphenicol The low colonisation-rate is difficult to explain. Prof ROBERT CRUICKSHANK suggested that the time available was probably too short for widespread colonisation

Salmonella Infection

Dr HELEN WRIGHT described an outbreak of 3 cases of *Salmonella typhimurium* enteritis traced to a dairy herd in which endemic infection had become septicæmic in some of the cows during calving, with resultant infection of their milk. The probable source was stored straw, which was heavily infested with rats and mice. The risk of salmonella infection of man from bovines is not sufficiently recognised, nor is the bovine septicæmic form in cows during calving Closer liaison between bacteriologists and veterinarians is essential if such outbreaks are to be traced to their source

New Inventions

A TUNNELLER FOR BYPASS ARTERIAL GRAFTS

THE bypass arterial graft is useful in certain cases of occlusive disease of the major limb arteries One of its main virtues is that exposure of the proximal and distal arterial segments is done through relatively short and separate incisions and the existing collateral circulation remains undisturbed The arterial graft must therefore be drawn through a blind tunnel joining the two incisions Various instruments have been employed to make the tunnel and to draw the graft into position A small œsophagoscope and biopsy forceps are used by Owen and Rob[1] and Crawford and De Bakey[2] suggest a vein stripper

The simple device described here is designed for the purpose and has worked very efficiently The tunneller consists of a streamlined head which serves as a dilator and is so shaped that it will slide easily in either direction The nose of the instrument is perforated by a small transverse hole placed $^1/_4$ in from the tip The head is connected to a flat handle by a rigid but slightly flexible shaft (fig 1) To create a femoropopliteal tunnel, Hunter's canal is opened in the groin and dissection with a finger is begun downwards and medially alongside the femoral artery The tunneller is then introduced into this space and passed distally until the head is felt in the popliteal wound The instrument is then almost withdrawn and repassed once or twice to ensure that the tunnel has been adequately dilated. When the tunneller is felt to run smoothly, its head is exposed in the popliteal space and is withdrawn from the wound. The arterial graft is then secured to it by a suture engaging the graft and passing through the transverse hole in the head (fig 2) When the suture is tied, the artery and the tunneller become locked together, the nose of the instrument fitting snugly into the lumen of the graft. Rotation of the artery in the tunnel is avoided by keeping the flat handle of the tunneller in the same plane as that in which the instrument and the graft are withdrawn to the groin wound It is as well to test that the graft is lying comfortably in the tunnel by irrigating from one end with saline solution and observing a free flow at the other end. The longer tunneller works equally well in an ileopopliteal bypass and is then passed, from above, under the inguinal ligament lateral to the external iliac artery

Fig 1

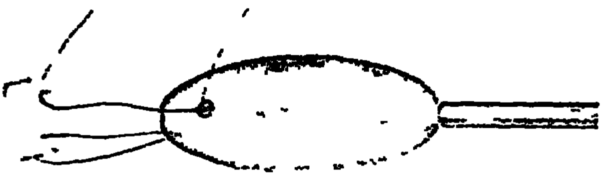

Fig 2

The tunneller is made in two sizes, 19 inches and 16 inches and can be obtained from the Genito-urinary Manufacturing Co Ltd

Reviews of Books

The Essence of Surgery

C STUART WELCH, M S, M D, PH D, professor of surgery, Albany Medical College of Union University, SAMUEL R POWERS, Jr, M D, M SC D, professor of experimental surgery, Albany Medical College Philadelphia and London W B Saunders 1958 Pp 320 49s

GIVEN the time, a well-stocked library, an efficient secretary, and a competent psychiatrist (to dispel lingering inhibitions), any final-year student with a literary bent could write a passable 2000-page “ standard ” textbook of surgery No final-year student could compile a 300-page Essence of Surgery—a task that few experienced surgeons would care (or dare) to tackle It would be too much to claim that Professor Welch and Professor Power have been entirely successful, but their book is a gallant and welcome attempt at the almost impossible Its “ purpose is to present a concept of surgery which will assist readers to a more detailed and definitive study of this division of medicine ” in other words, they aim not at casting a first quick glance, but at exposing the very foundations of their art and science The centre of their discussion is acute physical injury, interpreted in its widest sense, and in broad outlines they consider the therapeutic problems presented by its three main features—loss of body tissue, loss of body fluids, and infection Principles of surgical management are then applied to “ extirpative surgery ” (as exemplified by carcinoma of the colon), to “ reconstructive surgery ” (as practised in skin-grafting), and to “ physiological surgery ” (as in operations on endocrine glands) A chapter deals with the guiding principles of preoperative and postoperative care, and another analyses the basic rules of surgical technique

It is the book’s special merit that it avoids the two most common and most irritating characteristics of Introductions its authors are neither matey nor patronising Indeed, they assume a level of intelligence, a keenness of interest, and readiness to ponder basic issues which few first-year medical students possess and their essay may well prove more helpful to teachers of undergraduates than to undergraduates themselves In the best American tradition the book includes a fine chapter on the history of surgery the authors clearly regard this as part of the Essence and not (as surgical writers often do) as a means of imparting literary *bon-ton* Their hero is Theodor Billroth and he certainly deserves emulation as much as Paré, Hunter, and Lister deserve a rest from hagiographers

Biological Aspects of Cancer

JULIAN HUXLEY, D SC, F R S London George Allen & Unwin 1958 Pp 156 16s

Dr Huxley suggests that autonomous tumours can be logically regarded as members of new biological species with their own specific types of self-replication and with the capacity for further evolution by the incorporation of suitable mutations In judging whether a tumour is autonomous, he adopts the standard criteria of pathology, and he approves the methods and subjects that have in the past been used to study the nature and origin of this phylum Some curious examples of cellular proliferations are, he suggests, well worth more intensive investigation Much space is given to melanomas in drosophila and in old grey horses, though he has doubts, felt by many other workers, about their autonomous status Amphibia are particularly suitable as experimental material

The change underlying autonomy Dr Huxley regards as a deviation of metabolism, and “ any agency capable of pushing cell metabolism in a certain general direction—that of upsetting the normal growth balance so as to favour non-limited replication—is capable of initiating a tumour ” The words used through the decades change somewhat They still leave us ignorant of what this change is

Some more recent topics in cancer research are mentioned, with references to new review articles The opinions of their authors are sometimes adopted without that gruelling critical inspection of the evidence which first-hand experience provokes

Alexander Gordon, M D, of Aberdeen (1752-1799)

IAN A PORTER, M B, lecturer in the department of bacteriology, University of Durham Edinburgh Oliver & Boyd 1958 Pp 92 12s 6d

IN his epoch-making essay on *The Contagiousness of Puerperal Fever*, Oliver Wendell Holmes gave pride of place to the observations of Dr Gordon of Aberdeen, printing in capital letters an extract from his *Treatise on the Epidemic Puerperal Fever in Aberdeen*

> “ But his most terrible evidence is given in these words ‘ I arrived at that certainty in the matter that I could venture to foretell what women would be affected with the disease upon hearing by what midwife they were to be delivered, or by what nurse they were to be attended during their lying-in and almost in every instance my prediction was verified ’ ”

Apart from the essay and the treatise little or nothing has been known of Alexander Gordon, and little credit has been given to him for his shrewd observations Dr Porter’s short biography is therefore important, and he has done it well, finding new material and correcting errors There are some remarkable case-notes the successful delivery of a 16½ lb baby, a cæsarean section, an extra-uterine conception in which the whole skeleton was eventually discharged per rectum over a period of three months, and a curious case of expectoration of bile The best chapter is the one dealing with the epidemic in relation to the state of knowledge of puerperal fever at the time

Alexander Gordon well deserves to stand in the limelight as an important figure in medical history Yet he has been so far forgotten that he is not mentioned in Comrie’s two-volume *History of Scottish Medicine*

Stammering and its Treatment

FRANKLIN BROOK, L C S T, late speech therapist, Huddersfield Child Guidance Clinic London Pitman Medical Publishing Co 1957 Pp 134 21s

MOST doctors know little about stammering, and they are inclined to tell worried parents that the child will “ grow out of it ” if they don’t fuss, and to advise the child, a few years later, not to make such a tragedy of a “ minor ” handicap There is a grain of truth in the doctor’s advice, but without individual understanding and treatment it cannot be guaranteed that the early stammer will fade away, and the later secondary stammer cannot be regarded as a trivial easily surmountable handicap Mr Brook starts by discussing the ætiology of stammer, which he attributes to nervous or emotional instability combined with some illness or stress situation The rest of the book is devoted to a description of primary and secondary stammering and the methods now used for their treatment Relaxation exercises, the use of voluntary stammering, the supportive therapy necessary to help the stammerer persevere, group therapy and “ free speakers’ societies,” and the need for the speech therapist’s guidance, are all discussed

---

British Surgical Practice Surgical Progress 1957 (London Butterworth 1957 Pp 442 *52s 6d*)—The new progress volume is even better than usual It makes some slight departures from its accustomed form there are only two original articles (on ulcerative colitis and lesions of the feet in diabetes), and the thirteen critical surveys which follow range more widely than hitherto, reporting the advance in antibiotics, infections, diseases of the alimentary system, pulmonary, vascular, endocrine and orthopædic surgery, gynæcology, breast disease, genitourinary, ear, nose, and throat, and cardiac surgery, and anæsthesia Each survey is followed by abstracts of recent relevant papers, and they are more easily digested thus than in previous volumes, where they were all grouped together The “ noter-up ” (is there not a more attractive name ?) keys the contents of this volume and its six predecessors to the original work The book is a good companion for the busy surgeon who falls asleep over his journals after dinner It is admirably written, beautifully produced, and nicely selective—as one would expect from its editors, Sir Ernest Rock Carling and Sir James Paterson Ross, and their eminent team

THE LANCET
LONDON 14 JUNE 1958

Carcinoma of the Prostate

HUGH YOUNG was forty years ahead of his time when he said that cancer of the prostate was a common disease, he estimated that 1 out of 7 cases of prostatic enlargement in men over 50 was cancerous[1] What was then a bold assertion would now pass as an understatement[2–5] The startling discrepancy between the clinical and post-mortem prevalence of prostatic carcinoma has virtually demolished ideas of cancer as an essentially killing disease FRANKS showed that the "latent" type of prostatic carcinoma is histologically indistinguishable from the ordinary type many latent tumours invade the prostatic capsule, the lymphatics, and surrounding structures[6 7] Yet they neither cause symptoms nor shorten life Cancerous growths in the prostate seem to have a wide range of "biological potential", and this potential we can assess only in retrospect

For the type of cancer which would eventually kill the patient, radical surgery remains the only treatment that offers a prospect of cure[8–10] In any series the proportion of cases found suitable for operation depends on the stage at which the growths are diagnosed and on the criteria of operability FERGUSSON,[11] who has reviewed 313 consecutive personal cases, remarks "In health-conscious communities, where routine examinations are frequently performed, the opportunities for detecting early operable growths by rectal palpation will be correspondingly increased", and this may partly account for the disparity between operability-rates reported from some clinics in the United States and in this country In many patients complaining of mild urinary symptoms the growth will have already become inoperable, and in the overwhelming majority of FERGUSSON's cases there was either extensive local induration or evidence of distant metastases This is a grim state of affairs, and whatever the value of cytological diagnosis, salvation will not come from even routine examination of prostatic smears[12–14] Most surgeons would regard a normal life expectation of less than eight to ten years as a contra-indication to radical surgery[15], and a raised serum-acid-phosphatase level betokens bony metastases[16] On the other hand, neither slight fixation of the growth on rectal palpation nor the discovery of discrete primary nodules, which are occasionally associated with concealed distant deposits, prohibits operation Fixation may be inflammatory rather than neoplastic, and if metastases are revealed postoperatively, they can always be treated by other methods

Only a few years separate the first attempts at radiotherapy from the first radical prostatectomy[5 17], but irradiation still suffers from the severe disadvantage that an adequate dose almost inevitably causes grave damage to surrounding structures Cancer of the prostate was also among the first tumours to be treated by radioactive isotopes[18 19] and FLOCKS[5] has described improved methods of introducing radioactive gold (^{198}Au) But the isotope cannot be confined to the site of injection, and uncontrolled dissemination, even if not necessarily harmful, cannot but cause uneasiness In contrast to radiotherapy, endocrine treatment—dating from the epoch-making work of HUGGINS and his fellow-workers[20 21]—has completely transformed the management of prostatic cancer FERGUSSON prefers oral œstrogens to castration as the first method of growth suppression and he feels that, so long as the dosage is sufficiently high, nothing can be gained from combining the two Stilbœstrol 30 mg daily is tantamount to pharmacological castration, and in FERGUSSON's series the side-effects of 100 mg daily were neither more severe nor more frequent than those from the far smaller doses originally employed[22] Œstrogen therapy eliminates the need for a small but unpalatable operation, it may influence extragonadal as well as testicular sources of androgens, and it may exert a direct cytotoxic effect on the growth itself Newer preparations are on trial, and first impressions with diethyl stilbœstrol diphosphate,[23] given intravenously in doses of 500 mg daily for up to ten days, have been distinctly favourable Breast changes, shrinkage of the genitalia, and occasional nausea and vomiting are common with œstrogen therapy, but they are rarely troublesome enough to require cessation of treatment. Whatever the method of gonadal suppression—and castration still has its advocates[24 25]—three facts can be stated categorically First, œstrogen therapy significantly prolongs life, at any time between six months and three years after diagnosis the mortality-rate of treated patients is roughly half the mortality-rate in earlier untreated series Second, relief from urinary and metastatic symptoms in most cases makes survival more tolerable and the end less distressing Third, most, if not all, tumours show signs of reactivation after months or years In some cases this undoubtedly reflects a change in the tumour cells themselves from being largely hormone-dependent they graduate to a higher degree of autonomy In others, however, reactivation seems to be a response to a compensatory over-production of growth-stimulating hormones in extragonadal sites This second phenomenon forms the rational basis of adrenalectomy[26–28]

FERGUSSON submits to operation (which he normally performs in two stages) only those patients who have relapsed after a good initial response to endocrine therapy Hence the 19 patients in his series who were operated on were all men with advanced disease, and most had widely disseminated metastases Adrenalectomy is well tolerated, and, provided the patient adheres to a strict though not too rigorous postoperative regime of cortisone, the risk to life is small Unlike œstrogen therapy, this is essentially symptomatic treatment Striking relief from metastatic bone pain and recession of urinary and pulmonary symptoms can be expected with fair certainty but radiographic signs of metastases usually persist, there is rarely any significant fall in the serum-acid-phosphatase level (though the urinary drain of calcium may be temporarily halted), and it is doubtful if life is materially prolonged

There is a possibility, indeed a likelihood, that growth-stimulating hormones are elaborated in other, unknown, sites even after gonadal suppression and adrenalectomy Various methods of suppressing pituitary function are aimed indirectly at these unidentified target organs, and the procedures now on trial range from formal hypophysectomy to diverse forms of irradiation.[29-33] To say that they should still be regarded as tools of research rather than of therapy is not to deny their value Because neither surgery nor radiotherapy can be relied on to secure total suppression of pituary function,[34] it is fortunate that complete ablation seems unnecessary to produce symptomatic relief " Surgical hypophysectomy," **FERGUSSON** says, " demands a certain standard of fitness which automatically excludes a proportion of otherwise eligible patients, whereas the transnasal introduction of radioactive material into the gland carries little risk " Yttrium, a powerful β-ray emitter, gives promise of a higher success-rate and fewer complications than radon or radioactive gold Two seeds are customarily implanted, one via each nostril, under X-ray control [35], and necrosis ensues over a radius of about 4–8 mm around each seed [36] The chief complication of earlier techniques, but not so far encountered with yttrium, was irradiation damage to the optic chiasma, leading to partial or complete blindness Meningitis is usually prevented by the combined effect of irradiation and of antibiotics, and leakage of cerebrospinal fluid through the sizeable dural perforations necessary for introducing the yttrium seeds usually stops spontaneously The degree of suppression of pituitary function can be assessed indirectly by estimating urinary hormone excretion,[30] [37] by measuring the radioactive-iodine uptake in the thyroid, and by observing the development of clinical signs of hypopituitarism [38]

Leaving the heights of experimental surgery, it is well to remember that simple palliative measures still have a useful place Because of the consistence of the cancerous prostate, urethral dilatation usually yields more lasting benefit than can be expected in benign hypertrophy. If further relief is required **FERGUSSON** prefers perurethral resection (which can be combined with biopsy) to cystostomy drainage, and, where benign hypertrophy coexists, even palliative prostatectomy may be indicated **FLOCKS** [5] aptly remarks that the last fifty years " have made the urologist who works with prostatic cancer a surgeon, a chemist, an endocrinologist, and a radiologist ", but, above all, he still needs to be a man of understanding, patience, and compassion

Water and Tap

To meet the needs of expanding industries and new housing estates, many of the larger *municipalities and* water undertakers have had to augment and improve their waterworks, often far beyond their own boundaries, and in so doing they have often been able to help the villages through which their pipes and aqueducts are laid Meanwhile the Government have been concentrating central financial aid on the smaller local authorities, helping them to bring piped water to villages, hamlets, farms, and whole areas of the countryside where it never ran before A series of Acts of Parliament since 1944 have made £75 million available from central grants, and these have often been supplemented by corresponding amounts from the county councils, so that the rural district council, the county council, and the Government each pay a third of the cost By the end of 1957 some £24 million had been paid or promised as grants from the central funds, and the total value of all new waterworks authorised in England and Wales between August, 1945, and December, 1957, was well over £200 million These figures from the Ministry of Housing and Local Government [39] show that, between the successive waves of economy restrictions, a good deal is being accomplished, and the consequences can be far-reaching The drift from the countryside is not just a matter of the attraction of bright lights, cinemas, and city shops those who have seen a wider world often revolt against inconveniences that their forefathers had to endure The pump or the well in the garden, the path to the little stream, and the old water-butt below the roof may be very picturesque, but to most women a tap in the kitchen beats the lot In these days of a predominantly urban economy, it may seem not unsatisfactory that 95% of the population enjoy piped water But that leaves another couple of million people without it

Like many of our other national institutions, British water undertakings have grown up haphazard—some to meet specific local needs, some to exploit commercial opportunities, and some as part of the traditional patronage of bygone landowners Consequently they present an irrational and uneconomical tangle of pipes and interests But the imperfections go deeper than the

machinery. Many of the smaller water undertakers are obliged to rely on part-time or semi-skilled staff—which means that too much is left to luck. Whether radical reorganisation would bring more efficiency is a matter of opinion. A national water grid has been suggested, but the countryside seems sceptical about promises of economy and better service from nationalisation of industries, and has said so quite clearly. The Government have compromised by pressing for a limited amalgamation of water undertakings as a first step. At present about half the population are served by the 55 largest undertakers, while the other half are served by about 900 smaller bodies. It is these 900 that are the targets for the Government's fire. They have been encouraged to get together, to prepare plans for amalgamation, they have been exhorted to bestir themselves, and they have been threatened with force. A handful have taken heed, and by the end of last year twelve amalgamation orders had been made, affecting 25 undertakings, and a further eight orders affecting 30 were awaiting the Minister's approval. The Government are steadily intensifying their attack: compulsory powers are to be invoked in five areas, and the shadow lies over many more. It is a pity that such coercion should be necessary and that a rational policy should have to be applied against local opposition. But many a countryman would sooner go down fighting under the might of compulsory powers than be hurried by circulars from Whitehall. It is essentially a matter of public relations. If the Government have neither the time nor the patience to pursue the reasoned approach, then their bulldozer technique seems the only alternative.

But more than administrative efficiency is at stake, for there is a very real need to conserve Britain's water resources and use them to the best advantage. Many underground waterbearing strata are becoming seriously depleted, or contaminated by saline infiltration. Abstraction of well water on a large scale has now been brought under some measure of control, and in water-scarce areas restrictions or refusals have been imposed on sinking extra bore-holes. Also the question of waste during distribution has been raised: some water undertakers tolerate enormous leakage in their systems—sometimes because they find it more profitable to catch additional water for the headworks than to relay the leaking mains. Some authorities eagerly undertake capital expenditure on long loans but cavil at paying for proper routine maintenance out of their current revenue. Water-supplies evoke a curious mixture of business, engineering, and public-service interests, whose interplay can notably affect the happiness and health of a community.

Annotations

ASME

IN theory, the General Medical Council have always wanted each medical school to use its teaching resources in the way it thinks best, but in practice their *Recommendations* have been so detailed as to prevent any considerable departure from the conventional curricula. In education, as elsewhere in medicine, progress is often impossible without experiment, and anyone who doubts whether the present training of medical students is the best possible should be grateful to the Council for the courageous decision they made last year, which promises much more liberty to any medical school which qualifies for it by devising a well-considered plan. In commenting a fortnight ago on Dr Tanner's proposals for a new kind of preclinical curriculum, we expressed some doubt as to whether the teachers of any existing school would be able to agree on so radical a change from what is customary, and we shall in fact be surprised if the majority of schools accept the Council's challenge. But what is important is that a few should do so, and that the way is at last open to pioneers—even if one or two new schools have to be created in order to put their ideas to the test.

Thus the reform of medical education, so often debated in theory, has become something practicable even in Great Britain. No better moment, therefore, could have been chosen for establishing the new Association for the Study of Medical Education (ASME), which should prove as useful in this country as the Association of American Medical Colleges has proved in the United States. The intention is that it shall represent all interests in medical education, but particularly perhaps the people actually responsible for training students, and it will therefore have corporate as well as individual members. These corporate members will be universities, medical schools, and licensing and other bodies interested in medical education, and they will be entitled to send two delegates to each meeting. The functions formally laid down for the Association are (1) to exchange information, (2) to organise meetings, (3) to maintain an information bureau, (4) to encourage, promote, or conduct research into matters connected with medical education, and (5) generally to do such other things as it may think useful. Its first conference will be held on Sept. 25 and 26, when the subject will be Experiment in Education.

Though the Association was formed at a meeting called by the Royal College of Physicians of London, and has the use of the college premises, it is an independent organisation. The executive committee for 1958 has the following members:

Prof. Robert Platt, F.R.C.P. (Manchester), Sir Russell Brain (London), Prof. J. H. F. Brotherston (Edinburgh), Sir David Campbell (Aberdeen), Prof. A. M. Claye, F.R.C.O.G. (Leeds), Dr John Ellis (London), Prof. H. W. Fullerton (Aberdeen), Prof. I. Goldby (London), Prof. J. W. Howie (Glasgow), Dr Alastair Hunter (London), Dr J. G. McCrie (Sheffield), Prof. G. P. Meredith (Leeds), Mr M. F. Nicholls (London), Sir Harry Platt (Manchester), Prof. H. Scarborough (Cardiff), Dr Richard Scott (Edinburgh), and Prof. A. P. Thomson (Birmingham).

ANÆSTHESIA FOR THE EMPHYSEMATOUS

EMPHYSEMATOUS patients give the anæsthetist many problems, some of which have been reviewed by Nunn.[1] Induction of general anæsthesia may be troublesome, since emphysematous patients are usually bronchitic as well, and the sensitive bronchial mucosa is easily irritated by gases such as ether or by the mechanical stimulation incidental to intubation. Moreover, induction may take longer than usual owing to dilution of the gas in the abnormally voluminous lungs, inefficient gas mixing, and reduced absorption of gas from poorly perfused alveoli—

---

[1] Nunn, J. F. *Brit. J. Anæsth.* 1958, 30, 134.

although this is not of great practical importance with gases such as halothane and cyclopropane which exert their effect at low blood levels

It is beneficial to abolish hypoxia, but if anæsthesia is conducted during spontaneous breathing and the stimulus to respiration has come to be, not an increased pressure of carbon dioxide, but lowered pressure of oxygen in the arterial blood, then alleviation of hypoxia may lead to diminished tidal volume and dangerous retention of carbon dioxide[2] Artificial ventilation disposes of this hazard but introduces others—including hyperinflation of the lungs, which, by increasing the intrathoracic pressure and preventing venous return, may add cardiac to respiratory embarrassment Considerable pressure may have to be applied in the inspiratory phase to overcome airway resistance, and the sudden reduction of this pressure causes rapid gas flow in early expiration, which may lead to closure of the finer bronchi with gas trapping and hyperinflation Since a grossly subatmospheric pressure applied in the expiratory phase accentuates this tendency, Nunn[1] recommends the employment of only a slight negative pressure (of the order of −5 cm of water) in the latter part of expiration

Rupture of alveoli with escape of gas into the interstitial tissues of the lung and thence to the mediastinum, pleura, and subcutaneous tissues is another possible complication of artificial ventilation,[3 4] especially if high pressures are used, alveoli with free airways will be exposed to the full inflationary pressure, whereas alveoli with obstructed airways will not,[5] so a pressure gradient between adjacent alveoli may become great enough to rupture their walls Sometimes also it is difficult to establish spontaneous respiration after artificial ventilation Auld[6] has reported a case in which spontaneous breathing was not resumed until the patient's arterial-blood-oxygen had fallen to a level low enough to supply the hypoxic stimulus, although in Nunn's[1] experience the chief difficulty has been to adjust the carbon-dioxide pressure to the appropriate level He considers that spontaneous respiration is unlikely to start if the arterial carbon-dioxide pressure is more than 10 mm Hg below the patient's customary pressure, which may not be far short of the level at which respiration is depressed by carbon-dioxide narcosis Hence, as arterial-blood-gas analysis is seldom practicable, it may be necessary to resort to the expedient of alternately raising and lowering the carbon-dioxide pressure until the correct level is found Artificial ventilation is, of course, essential for thoracic operations, and despite its drawbacks it is generally advisable for emphysematous patients undergoing extrathoracic operations as well, since it is the only means of ensuring adequate gas exchange

Preoperative assessment of the patient's respiratory function is important Before thoracic operations the results of lung-function studies will be available to the anæsthetist, but in other cases he will usually have to make his own assessment, often rapidly and with few technical aids The history and physical examination may supply valuable information, but when there is a question of disturbed respiratory function these are not enough The most useful test of ventilatory function is determination of the forced expiratory volume (F E V)—that is, the quantity of air which can be expired in a given time after a full inspiration—and this requires only a spirometer with a simple timing device[7] Figures below normal indicate obstruction to expiratory air-flow, and the findings can be expressed in terms of the more familiar maximum breathing capacity by multiplying by a factor[8 9] The one-second F E V is normally more than 70% of the vital capacity,[10–12] which is estimated at the same time, and a subnormal percentage indicates airway obstruction Successful antispasmodic therapy for asthma will increase the F E V, but it may also increase the vital capacity, so that the F E V percentage may remain unaltered until the vital capacity has been restored to normal[13] failure of a low F E V percentage to rise eventually in response to vigorous therapy despite absolute increases in the F E V and vital capacity is highly suggestive of underlying emphysema Unfortunately there is as yet no simple way of estimating the gas tensions of arterial blood, but, if metabolic alkalosis can be excluded, the serum-bicarbonate content of venous blood will indicate whether or not carbon-dioxide retention is present

In view of the vital importance of preoperative assessment of respiratory function, few will dispute Hugh Jones' opinion[14] that facilities for determining the F E V and the serum-bicarbonate level should nowadays be available to the anæsthetist

CENTRAL HEALTH SERVICES COUNCIL

At the inception of the National Health Service there was a strong hope that the Central Health Services Council, with its well-qualified members, would take a prominent part in the development of the service—offering, as well as responding to requests for, advice on many important issues This hope has been disappointed, and, though some useful surveys and recommendations have been made, successive annual reports by the Council have offered mostly small beer—and, which is inevitable, also rather flat beer, for the findings of the Council or its related committees are often reflected in official policy before the annual report appears The latest[15] covers 1957

The Minister of Health[16] has acted on the recommendations of a subcommittee set up to consider the control of dangerous drugs in hospitals[17] A joint subcommittee of the English and Scottish Standing Medical Advisory Committees, whose interim report appeared in 1956,[18] recommended in its final report last year that the supply of welfare orange juice should be discontinued for children over 2 years of age, and that the vitamin-D content in welfare foods and cereals should be reduced, and these recommendations have been adopted The Standing Dental Advisory Committee considered the report of the Committee on Recruitment to the Dental Profession (the McNair Committee) and informed the Minister that additional clinical teaching facilities were urgently needed

An inquiry by the Standing Tuberculosis Advisory Committee threw further light on tuberculosis in immigrants The committee found that on Sept 11, 1957, 245 temporary residents who had arrived in the previous year were being treated for pulmonary tuberculosis as in-patients, and 205 of these were presumed to have had the disease on arrival in this country, the corresponding figures on May 13, 1953, were 128 and 87 Of these 205 patients 53 were from India or Pakistan, 36 from the Irish Republic, 35 from Hungary, 33 from other countries in Europe, 23 from Commonwealth countries other than India, Pakistan, or the West Indies, 16 from the East (outside the Commonwealth), and 8 from the West Indies, the nationality of 1 was not recorded Apart from the Hungarian refugees, who constituted a special problem, the great majority (120) of the 170 immigrants suspected of having had tuberculosis on arrival were citizens of the Commonwealth or the Irish Republic The Irish medical authorities believed that few of those leaving the country were infectious, there had lately been a vigorous campaign for B C G vaccination, and it was expected that within two years almost all young people emigrating would be tuberculin-positive

The report is presented by Lord Cohen of Birkenhead, who has succeeded Sir Frederick Messer as chairman

UNCOMMON OBJECTS OF THE SEASHORE

BUCKET and spade are now out of date, but it will not be long before the folding boat, the snorkel, and the new bikini are packed into the car and away we go Those who practise by the seaside know that the English summer holiday is medically uninteresting except for drownings (many of which are avoidable) and too many feet cut by broken glass The more dramatic perils of the foreshore are rare in this country A few luckless paddlers stand on weaver fish (and know all about it) [1], but our sharks are too small, our seasnakes are extinct, and it is only rarely—and for reasons which are not very clear—that we are invaded by the highly poisonous jellyfish Last year we had warning [2] of the approach of a fleet of Portuguese men o' war (*Physalia physalis*), but as far as we know no-one was stung Glistening pink and palest blue, these are some of the most lovely things to be seen in tropical seas, but contact is likely to blind the eye to this radiant beauty Even more painful, and sometimes fatal, is the sting of the seanettle, *Cyanea capillata*, which enters home waters even more rarely but has some fame as the origin of one of Sherlock Holmes' more egregious bloomers In the tropics these and other poisonous coelenterates are not uncommon, some of them floating free and some, such as the stinging coral (*Millepora alcicornis*), fixed Most English children are warned against jellyfish and sea-anemones, such old wives' tales must not be treated lightly, but experience shows that many of our native species are seldom or never noxious An authoritative statement on this by a marine biologist would be useful

The structure of the stinging apparatus on the coelenterate tentacle is most elegant Our knowledge of the toxicology of the substance which is injected is based largely on work done many years ago and by modern standards unconvincing, but it seems likely that the most deadly of these creatures produce at least two poisons Local effects range from erythema to necrosis, and the slow healing of wounds caused by coral scratches is probably due to some toxic substance The pain may be local but more often radiates over a wide area and may be sufficient to paralyse the victim The second poison seems to act centrally, interfering with respiration and causing primary shock Drowning is the most usual cause of death, but some of those brought ashore alive die from respiratory failure Morphine (if available) alleviates the pain, but other treatment must depend more on medical art than on the sciences Prevention is limited to the avoidance of jellyfish—especially if they are unlike the familiar kinds—and it is worth remembering that the tentacles are surprisingly long The advice to wear tight-fitting long woollen underwear is unlikely to be acceptable to a generation intent on following Eve as far as the opinion of the public or the Watch Committee will permit

Those who wish to learn more of these perils should turn to an article by Halstead [3] which contains good illustrations of some of the more poisonous coelenterates

THE DOCTOR AS MARRIAGE COUNSELLOR

"AND so they got married and lived happily ever after" From our earliest years we are exposed to propaganda about the effortless bliss attained in marriage Though the experience of our adult years makes clear that there are many exceptions, the ideal stubbornly persists, however much reality diverges from it, and the serenity of the families pictured in the advertisement columns of our newspapers, clustered enthusiastically round a new washing-machine or acclaiming a breakfast cereal, often contrasts harshly with the problems and difficulties of real families described in the news columns

The publicity given to broken marriages today suggests that the institution of marriage is less stable than it was in, say, Victorian days Easier divorce, the social unrest of two wars, the emancipation of women, and Legal Aid have all tended to make the marriage tie less durable But the more durable Victorian marriage often in fact exacted a good deal of endurance, and its durability was sometimes bought at a price of unhappiness that must have been destructive of the relationship between husband, wife, and children If the community accepts divorce more readily today, it also offers marriage support that was unknown in the past The social services offer material help, while the changing climate of opinion and the spread of health education permits a franker discussion of sexual problems The Civil Judicial Statistics published a fortnight ago [4] showed a fall of 578 in the number of matrimonial petitions filed in 1957 compared with 1956, and this decrease is a hopeful sign that the community's growing concern with the breaking as well as the broken marriage may offer stability on less rigorous terms

One of the most useful and youngest of these preventive services is marriage counselling True to our national tradition, it was started by voluntary workers, and much of the work is still in the hands of a group of voluntary societies, including the Marriage Guidance Council which receive a small annual subsidy from the Government In a less formal way, and without even this modest official recognition, the family doctor was, of course, even earlier in the field, and Dr Alfred Torrie has lately suggested [5] that whatever new services the community may offer—through the marriage-guidance societies, the probation officers, or psychiatrists—he should continue with this work To do so, he is favourably placed not only by his knowledge of his patient's family background, but also because the patient can turn to him for help without explicitly admitting that she, or he, has come for a consultation about a marriage rather than a disease In the consulting-room marital problems are seldom presented directly, instead, the patient consults the doctor about some vague ailment, looking back over his own years of practice, Dr Torrie regretted lost opportunities to recognise emotional stress behind a bodily illness The doctor who undertakes this exacting work must, he suggested, avoid rigidity and dogmatism, and practise toleration and patience But his patience must have limits except in a crisis, a patient must not be allowed to take up more than her due meed of the doctor's time "The time allocated has to be presented firmly and kindly just as a dose of sleeping pills with its limited ration " The doctor must be prepared for the patient to express hostility, and must regard it, not as a vote of no confidence, but as a sign that the patient, in search for security, is testing his good will The doctor who is used to laying down regimes for physically ill patients will, Dr Torrie admitted, find it difficult to resist authoritarianism in marriage counselling But authoritarian advice and instructions only perpetuate dependence and immaturity instead the patient must be helped to help herself The doctor must listen but offer no premature advice or solution, he must encourage the patient to find her own answer to her problem and to realise that the decision is wholly her own

[5] Address to a public meeting held by the London Marriage Guidance Council on May 8

In offering these suggestions Dr Torrie readily admitted that marriage counselling is not a technique but an art, but he believes that it is one to which the general practitioner, with his detailed knowledge of family background, can make a special contribution, as a specialist in first signs and symptoms

SUBLIMATION IN SURGERY

Low-temperature evaporation of water under vacuum to produce freezing, followed by sublimation of the ice, was already well known when Wollaston [1] demonstrated a new method of applying this principle before the Royal Society in 1813 Shackell [2] in 1909 applied the method to the preservation of biological materials, by freezing substances such as serum, virus, meat, and blood in a salt-ice mixture and drying them in vacuo Reichel et al [3] used a rapid method of freezing and drying serum in bulk, and finally raised the temperature again to complete the drying process The result of such a procedure was a porous solid which redissolved with remarkable ease, while many of the properties of proteins were preserved In 1918 Ward [4] foresaw the need for supplies of plasma, but his suggestion was not implemented till 1933 when the first products for clinical use were prepared by freeze-drying [5]

In 1950 Marrangoni and Cecchini [6] used arteries that had been freeze-dried for grafts and reported satisfactory results in dogs The experimental use of dura mater similarly prepared was reported by Sewell and Koth [7] Dura mater obtained aseptically, freeze-dried, and stored in vacuo was used clinically by Campbell et al [8] The introduction of chemical sterilisation [9] by ethylene oxide has led Stern [10] to devise a more practical technique Tissue removed at routine necropsy without aseptic precautions is placed in penicillin-streptomycin solution, trimmed to size and shape, then sterilised in ethylene oxide for half an hour Freezing is accomplished in ten minutes by carbon-dioxide ice and 95% ethyl alcohol, and the material can be stored at −70°C until it is convenient to sublimate the ice at a vacuum of 0 3–0 4 μ over twenty-four hours Grafts are stored in sealed glass tubes at room temperature After reconstitution with water or saline for about twenty minutes, the dura mater is tough and pliable, "a bit more chalky in colour and a bit more leathery or 'chamoislike' but otherwise physically similar to normal dura mater in its surgical properties "

Stern reports the use of the freeze-dried homologous graft in sixteen patients, in whom it proved uniformly satisfactory The tissue was used to repair dural defects resulting from removal of tumours, from previous injury, and after removal of the orbital roof, and no infection attributable to the graft was seen Histological sections of grafted tissue eight days and four months after implantation showed only mild cellular reaction at the suture line, and no more than slight adhesions to the brain From the patient's point of view, it is obviously a great advantage to avoid a second operation site for the purpose of taking a graft of fascia lata Sublimation seems to make homologous grafts if anything more acceptable to the host than are fresh grafts, and rapid freezing to keep the crystals of ice small seems to leave a product that is acceptable in its material properties No doubt further improvements will yet be made Ethylene oxide is volatile, and the vapour is noxious β-propiolactone has been recommended as an alternative [11 12] It must be remembered in grafting a sheet of fibrous tissue that the dead sheet acts mechanically until it is replaced by living fibrous tissue If the area is large this replacement must come from a suitable tissue in contact with one surface of the graft, otherwise growth must take place slowly from the edges, and the centre is likely to break down The new source of grafted dura mater therefore will be suitable enough for laying over a small dural defect, such as a fistula into a nasal sinus This is probably its most important use, the indications for dural repair for other purposes are less certain, and the advantages of a graft over a non-reactive gelatin film are problematical

WORKING PARTY ON HOSPITAL MEDICAL STAFFING

In the House of Commons last Tuesday, Mr Derek Walker-Smith, Minister of Health, announced the names of the members of the Hospital Medical Staffing Working Party They are as follows

Dr R R Bomford, Prof John Bruce, F R C S E, Dr J D S Cameron, Prof Andrew Claye, F R C O G, Sir Kenneth Cowan, F R C P E, Mr H C Edwards, F R C S, Dr G E Godber, Mr Norman Graham, Dr T Rowland Hill, Mr J E Pater, Prof Robert Platt, F R C P, and Mr T Holmes Sellors, F R C S

The working party, which is to study the principles on which the medical staffing structure in the hospital service should be organised, was appointed jointly by the Minister of Health and the Secretary of State for Scotland and the Joint Consultants Committee

From the All India Institute of Mental Health, Bangalore, and the Departments of Medical Statistics and Experimental Psychiatry, Medical School, University of Birmingham

When one of us (W M-G) visited India for a second time, he was again impressed by the youth of the 500 patients in the Mysore Government Mental Hospital, Bangalore, as compared with patients in most mental hospitals in this country The same impression of youth, of course, is gained in the streets and bazaars of India, where gay young men and women are everywhere to be seen, instead of the prevailing middle-aged people who hastily ply their business in the cities of Great Britain

The Bangalore Hospital, opened in 1937, is the only psychiatric hospital in Mysore State, serving a population of about 2 million In the hope of throwing new light on the universal problem of chronic mental patients, a survey of the chronic patients in this hospital has been made, using the method previously applied in an English urban mental hospital (Cross et al 1957)

The earlier survey was concerned with 1096 patients who had been in hospital for more than two years and comprised 78% of the total number in residence Of these chronic patients, two-thirds of the males and three-quarters of females had been in hospital for ten years or more Only 17% of the male and 9% of the female patients were under 40 years of age and 31% of the male and 50% of the female patients were at least 60 years old The ratio of female to male chronic patients (1 5 for all ages) increased with age In spite of an increasing admission-rate over the last few years fewer patients had become chronic after first admission than in earlier years, but modern treatments had obviously not prevented chronicity altogether, especially among schizophrenics It was also found that retention in hospital not only depended on the presence of offensive behaviour but also was often due to social and other factors not directly related to the biological symptoms of the mental illness Almost a third of the chronic patients had concomitant physical disease, and the proportion for those aged 70 years and over was outstandingly high (59%)

One would naturally expect very different findings in a hospital which serves an Indian community traditionally bound to accept and tolerate the chronic psychotic in its midst. In India, those patients who cannot exist within the family live for the most part as tramps, beggars, or mystics in the precincts of temples or other holy places The psychiatrist has little difficulty in spotting catatonics and paranoids in the entourage of temples and in the streets of towns and villages More than a third of the inmates in a beggars' colony which one of us visited in 1950 were said to be chronic psychotics In our own poor-law institutions in times gone by the state of affairs may well have been the same

Observations

The Role of Age-structure

In the hospital service in India the chronic mental patient constitutes a relatively small problem At Bangalore, at the time of our survey only 132 patients had been in the hospital for two years or more, and the accompanying table shows that over two-thirds of the males and over half the females were under 40 years of age

Life tables for India (United Nations 1954) show that the expectation of life at birth was 32 years, and even at the age of 25 it was only a further 30 years Thus, not only does the Indian chronic mental patient have a much shorter life than his British counterpart, because of communicable and nutritional diseases, but also the low life-expectation in the general population makes the total exposure to risk of mental breakdown far less

Studies in the incidence of mental disorder (Rose and Stub 1956) show age to be an important factor, the highest proportional rates occurring in the highest age-groups The mental disorders of later life are but rarely observed in the Indian mental hospital But, as communicable and other diseases are brought under control in India the expectation of life will rise rapidly and with it the incidence of mental disorder Not only will there be more admissions of mental patients, but also existing patients will live longer and become chronic The increase of pressure on mental-hospital accommodation which has been going on in this country for the past century seems likely to be repeated in India in a much shorter span of time.

Sex Ratio of Chronic Patients

Although the ratio of *all* male to female patients in the Bangalore hospital on any one day was 3 2, there was a small preponderance of female chronic patients The table shows that there were almost twice as many female as male patients aged 40 or over, though the number of such patients was small One explanation of this finding may be differential life-expectation, but available life tables do not indicate that women in India live significantly longer than men The comparatively low expectation of life of Indian women is sometimes attributed to high maternal mortality, and if this is so, chronic female patients may have proportionately less risk of dying from this cause, because mental patients have relatively low marriage and fertility rates

Social and cultural factors are, however, probably more significant In contemporary India, with its predominantly agricultural economy, the joint family system undoubtedly facilitates the return of the mentally handicapped male to his family Whereas the man is able to do simple work on the land cultivated by the family, a woman's value is judged by her childbearing capacity and household skills When a wife's abilities are reduced by mental disorder, there has been, until recently, very little to prevent a husband from discarding her and remarrying Moreover in most Indian cultures parents show greater loyalty to their sons than to their daughters, and this makes it more difficult for a sick daughter to return home Another consideration is the sheltered position of women in Hindu society, which makes a hospital reluctant to discharge a recovered patient if her relatives do not come forward and accept her Male patients are more readily discharged without the assent of relatives

Diagnostic Groups Role of Schizophrenia

The table shows that four categories suffice to classify the male Indian patients as regards diagnosis, and only

DISTRIBUTION OF PATIENTS ACCORDING TO SEX, AGE, AND PRINCIPAL DIAGNOSIS

Diagnosis	Age-group (yr)				
	<30	30–39	40–49	50 or more	Total
Males					
Schizophrenia	16	17	10	4	47 (*78 3%*)
Manic depressive reaction	—	1	—	2	3 (*5 0%*)
Epilepsy with postictal confusion	5	2	—	—	7 (*11 7%*)
Mental deficiency	—	1	—	2	3 (*5 0%*)
Total	21 (*35 0%*)	21 (*35 0%*)	10 (*16 7%*)	8 (*13 3%*)	60
Females					
Schizophrenia	7	18	12	11	48 (*66 7%*)
Manic depressive reaction	1	3	3	1	8 (*11 1%*)
Epilepsy with postictal confusion	1	4	2	—	7 (*9 7%*)
Mental deficiency	2	—	2	1	5 (*6 9%*)
Other	1	1	1	1	4 (*5 6%*)
Total	12 (*16 7%*)	26 (*36 2%*)	20 (*27 7%*)	14 (*19 4%*)	72

four females had principal diagnoses other than these Schizophrenia accounts for slightly more than three-quarters of the male patients and two-thirds of the females Though one should be cautious in comparing diagnostic groups of Indian and English patients, schizophrenics occur in roughly the same proportions of the two series Such a finding may not be true of other hospitals, but it would certainly not go against the expectation of many experienced psychiatrists who have worked in both countries The relatively high proportion of epileptic psychoses is of interest, but the numbers are too small for conclusions

The vastly different social and cultural backgrounds from which the two groups are drawn suggests that these factors are not of major importance in causation or in preventing chronicity If early childhood experiences and other environmental factors are crucial in schizophrenia it seems remarkable that certain schizophrenics tend to become chronic mental patients in spite of different ethnic backgrounds, though the findings in some small closed communities would not support this view (Eaton and Weil 1956) The studies of Slater and Shields (1953) indicate the major importance of genetic endowment in predisposing to schizophrenia, but whether or not a given person develops schizophrenic illness may well be determined by environment

Discharge of Chronic Patient

Underemployment and other social and economic circumstances prevailing in India make it easier for the family to devote time and attention to the welfare of a handicapped member Though poverty and overcrowded living conditions are widespread, these factors do not seem to play as great a part as social attitudes and customs

Many chronic patients who are not visited in hospital by their relatives belong to families which have broken from the obligations of the joint family system, lack strong family ties, and have no dominant elders who think it their duty to tend sick members at home When the elders dominated the family they often sacrificed the welfare of other healthy members to keep a psychotic relative out of hospital and to maintain secrecy about the illness Once such a patient is admitted, discharge may be made difficult by the fear that his return will ruin the marriage chances of the young women in the family It is hard to foresee what would happen to the still existing family sense of responsibility for its mentally sick members if full social insurance and the Welfare State were introduced into India

The public concept of mental disorder remains somewhat primitive in India In the countryside the patient is nearly always treated for "possession" If rituals and rites fail, he is regarded as having "brain disorder", which is believed to be incurable Once such a patient is admitted to hospital, the family are very sceptical of possible recovery and reluctant to receive him back, even if there has been a good response to treatment But, considering how far away they live, and how difficult the journeys, a surprising number of relatives visit and willingly accept the patient home albeit sometimes to physical restraint in the cowshed if he relapses

Reflections

These observations have some bearing on the problem, in this country as in India, of caring for mental patients within the community, as now so often advocated While few would dispute the general desirability of family care for the mentally handicapped, the current social pattern in Britain is very much against accommodating abnormal people in the community Only well-preserved patients are acceptable Behaviour which in India would go unheeded would in this country soon be brought to the notice of the police and the duly authorised officer, with the almost certain consequence of admission to hospital Though many psychotics who do not show dangerous propensities can live harmlessly outside hospital, they can do so only if the community is prepared to be tolerant and make allowances for them Moreover, for success, community care requires an adequate and active aftercare service under psychiatric direction

With life-expectation still increasing in Britain, a continuing change in the age-structure of mental patients is inevitable Mental disorders in general will almost certainly become more prevalent, and there is likely to be an increase in non-organic psychoses, which, since they are not killing diseases, are liable to become chronic People with a tendency to develop schizophrenia or manic-depressive psychoses late in life, after the normal period of childbearing, will not be weeded out by natural selection

Our earlier survey (Cross et al 1957) showed the importance of the double handicap of mental and physical disorder in the same patient, and the frequency of this combination increases rapidly with age Even when neither mental nor physical condition is severe in itself, they may together require hospital care for long periods

The solution of this difficult problem cannot be found by pulling down chronic wards (Bickford 1955) or by adding small psychiatric units to general hospitals Existing chronic wards should be improved, and planning of psychiatric hospital accommodation should not merely be directed to the treatment of recent and acute cases Though better domiciliary care is needed, it is unlikely to solve more than a small part of our problem Recent experiments in this field have led to an unjustified degree of optimism (*Lancet* 1958) In spite of modern methods of treatment and some increased tolerance for the abnormals in the population in the West, all indications are that the demand for chronic beds will grow rather than diminish throughout the world Some of this need can, of course, be offset by providing hostels and other halfway-house accommodation, though those advocating such facilities should not blind themselves to the fact that a hostel can be just as much a chronic ward with a new name and less medical and nursing care Advances in mental health are not made by administrative dodges or by giving new names to old problems

GENERAL MEDICAL COUNCIL

SESSION JUNE 3–5

SIR DAVID CAMPBELL's presidential address at the opening of the Council's 196th session was summarised last week (p 1220)

BRITISH PHARMACOPŒIA

Dr H GUY DAIN, re-elected chairman of the Pharmacopœia Committee, reported that Prof E J Wayne had been appointed chairman of the Pharmacopœia Commission The committee had considered the problem, which had to be solved before the next *British Pharmacopœia* was published, of legal difficulties in the transfer from the Imperial to the metric system

DIPLOMA IN PUBLIC HEALTH

The Council received the annual returns of examinations for diplomas in public health in 1957 These showed that no examinations were held by ten universities, including Oxford and Cambridge, and the Scottish and Irish Conjoint Boards 202 persons passed the examinations, and 40 were rejected The largest number of candidates (60) presented themselves at London University, and the next largest (19) at Edinburgh

UNIVERSITY COLLEGE OF THE WEST INDIES

Dr E R BOLAND, moving the recognition of the University College of the West Indies for the further period 1959–61, said that great strides had been made by this University College, which had already reached quite a high standard Certain further facilities had been recommended by the University of London The provision of the money necessary for these developments had been rather held up by the formation of the Federation of the West Indies, but the university had been assured by competent authorities that the money would be forthcoming The recommendation was agreed to

Medical Disciplinary Committee

THE PRESIDENT announced that the committee were now in a position to sign the revised rules of procedure If the Privy Council approved these, they would be laid before Parliament, and unless any objection was raised they would come into operation They included a new evidence rule devised in accordance with advice given by the Judicial Committee of the Privy Council

The committee also approved a new statement to be substituted for the Warning Notice hitherto published at the front of the Medical Register As now listed, the grounds on which practitioners have been adjudged guilty of infamous conduct in a professional respect include "gross and/or prolonged neglect of duties, and disregard of personal responsibilities to patients" and "improperly obtaining or attempting to obtain payments from the National Health Service or otherwise to which they were not entitled"

RESTORATIONS AND ERASURES

The Registrar was directed to restore to the Register the names of *Ernest Benjamin Dawe* and *Patrick Laurence Lyons* *William Arthur Channugam Nason* and *George William Franklin* were unsuccessful in their applications for restoration

Arthur George Davies, registered as of 2, Four Elms Road, Cardiff, Glamorgan, M R C S (1940), was summoned on a charge of infamous conduct in a professional respect in that he committed adultery with a woman patient, of which he was found guilty by the Divorce Court He was not present and was not represented Mr G J K Widgery, solicitor to the Council, said that at the Divorce Court Dr Davies had been ordered to pay the husband £1000 damages, this had not been paid, a receiving order had been made against him, and he had now been adjudicated a bankrupt. The committee directed the Registrar to erase his name This is subject to an appeal being entered within 28 days

Robert Lindsay, registered as of 8, St Ninian Drive, Inverness, M B Glasg (1945), was charged with being convicted at Inverness of stealing a newspaper from a railway bookstall, and committing a breach of the peace He was not present and was not represented

Mr Widgery said that Dr Lindsay was drunk and creating a disturbance, challenging people to fight, he was also seen to take a newspaper from a bookstall He had appeared before the committee in May, 1955, as a result of four convictions between November, 1951, and March, 1955, for committing breaches of the peace in Inverness where he lived Judgment had been postponed for two years, and last May the case had been dismissed ' I understand he had not been practising as a doctor since 1955, but is employed by a firm of public works contractors in the North of Scotland," concluded Mr Widgery

By reason of the conviction, the committee directed the erasure of Dr Lindsav's name He can enter an appeal to the Privy Council

POSTPONED JUDGMENTS

The committee received satisfactory information concerning *David Philip Lewis-Badgett* and *Joseph John McMenemy*, for whom judgment had been postponed This concluded their cases

Last November the committee postponed judgment for six months in the case of *Hari Shankar Badve*, provisionally registered as of Central Talkies, Malegaon (Nasik), Bombay, India, M B Bombay (1953), who had been charged with submitting false certificates of experience for full registration While the committee now judged him guilty of infamous conduct in a professional respect, after considering testimony to his conduct, they did not direct the Registrar to erase his name from the Register

In May, 1956, judgment was postponed for two years in the case of *James Watson Richmond*, registered as of Rossleen, Kelty, Fife, M B Glasg (1929) Dr Richmond did not appear and was not represented. After consideration in camera, the President announced that judgment was postponed until next November

Presenting the case of *William Frank Cruickshank*, registered as of c o Milne, Broxy Cottage, Westmuir, Cruickshank, Angus, M B Glasg (1935), Mr Widgery, said that from May, 1954, the committee had three times postponed judgment The Chairman said to Dr Cruickshank

> "The Committee once again are not satisfied that the evidence concerning your habits and conduct would warrant them in discharging the case They are, however, prepared to give you one further opportunity—and may I emphasise 'one more opportunity'? —of satisfying them as to your habits and conduct They have therefore postponed judgment for a further period of six months"

Patrick Francis MacDonald, registered as of c/o A MacDonald, solicitor, Main Street, Granard, Co Longford, M B N U I (1941), had had judgment postponed for one year following convictions in 1950, 1952, and 1956 involving drink Mr Taylor, appearing in his private capacity for Mr MacDonald, said that he had again been convicted Judgment was postponed for a further year

Arthur Alfred Hill, registered as of 25, Holywood Road, Belfast, M B Belf (1926), had been convicted in 1950 of driving a motor-car when under the influence of drink and in 1957 of supplying tablets to another person with intent to procure a miscarriage (for which he was sentenced to three months' imprisonment) At the previous session the committee had deferred this case so that the Council's solicitor might obtain further information on the circumstances of the second conviction

Mr Widgery then said he had had great difficulty in obtaining any information He now told the committee that he had been unable to get any documents from Belfast except by subpœnaing a detective sergeant This detective sergeant produced statements made to the police Mr Widgery said that Dr Hill supplied some ergot tablets to a man whom he would call "Mr C" which Dr Hill knew were to terminate the pregnancy of a woman These tablets did not have the desired effect The girl did not have a miscarriage and gave birth to a baby In his evidence the detective sergeant said that a man was accused as well, he was found not guilty Dr Hill "Is it a fact that the woman concerned had not taken any tablets?" Witness "That is so" He agreed that he took a statement from the doctor at 10 o'clock at night, when the doctor, who had been ill, got out of bed to make it

The committee took a very grave view of the convictions They were prepared nevertheless to take into consideration the representations Dr Hill had made and the testimonials he had submitted, and postponed judgment for one year

John Holbrook Hill, registered as of Locks Park, Brixham, Devon, M R C S (1938), was charged with having been convicted at Brixham in 1955 of being in charge of a motor-car when under the influence of drink and at Exeter Assizes last November for driving a motor-car when under the influence of drink and causing the deaths of two persons by dangerous driving, when he was sentenced to six months' imprisonment for each offence, to run concurrently

Mr J Talbot, counsel, said that on neither occasion was Dr Hill engaged on any medical duties He now almost abstained from alcohol Mr Talbot read testimonials which, he said, showed that his client was not only a man wedded to his work but also a man of ability and some considerable value to the community where he practised

The committee postponed judgment for two years

John McGregor, registered as of Blythswood, Carronshore, Falkirk, Stirlingshire, M B Glasg (1940), had two convictions of driving a motor-car when under the influence of drink—the first in 1953 and the second in 1958 The Chairman told him that these convictions indicated habits which were not only discreditable but might be a danger to patients Judgment was postponed for a year

Mr Bayliss appeared as solicitor to the Medical and Dental Defence Union of Scotland in the case of *James Stewart MacDonald*, registered as of Knockdale, Beith, Ayrshire, M B Glasg (1925), who had been convicted in 1949 and 1957 for driving a motor-car when under the influence of drink or drugs Mr Widgery said that he had also been before the General Medical Council in 1943 following convictions in 1937 and 1942 In the light of his earlier record the committee regarded with grave concern the convictions now proved, but postponed judgment for a year

NAVAL COURT-MARTIAL NOT A "COURT"?

Fintan Anthony Lennan, registered as of Little Manor, Frittenden Green, Staplehurst, Kent, was charged with having been convicted at a Naval court-martial on two charges of gross indecency Mr N Leigh Taylor, solicitor, argued that this was not a conviction within the Medical Act, 1956, which said that "if any fully registered person (a) is convicted by any court in the United Kingdom or the Republic of Ireland of any felony, misdemeanour, crime or offence" the committee might direct his name to be erased from the Register Mr Taylor submitted that the words "by any court" must mean a court of competent criminal jurisdiction If courts martial were included, why not the benchers of Inns of Court, the Solicitors' disciplinary committee, the medical services committees, or the stewards of the Jockey Club? If a court martial was included, the committee would have to accept as offences everything which could be tried by a court-martial—e g, being improperly dressed on parade Further, a conviction by a Naval court-martial was not a conviction for any other purpose of law His client, if anyone chose, could be brought before a competent criminal court and only then would he be convicted The inclusion of courts-martial led to the absurdity that if the same officers had "convicted" his client in Malta, on the same evidence and with the same judge advocate, the "conviction" would not be within the Medical Act, whereas at Plymouth it was

Mr C P Harvey, Q C, the legal assessor, said it had always struck him as odd that the committee had to accept the decision of a bench of lay magistrates in this country but not the decision of the High Court of Australia confirmed by the Court of Appeal in Australia "There are so many absurdities," he remarked

Mr Taylor replied that there were grounds for excluding all courts which did not try cases by the law of the United Kingdom In the case of courts-martial, there could not be any grounds for excluding this offence if it was tried in Malta and including it if it was tried in Plymouth, or, as might happen in wartime, if the offence was committed in Plymouth and the trial took place in Malta

Mr Widgery, replying to the submission, said "We are dealing with offences against the law of the land It is not a matter of Naval discipline nor of the rules of the Turf" The Legal Assessor advised the committee that this was a conviction within the meaning of the Medical Act of 1956, and the Committee, accepting this advice, found the convictions proved

Mr Taylor said that Dr Lennan had the misfortune to be a homosexual It was not a crime to be a homosexual the crime was to break the law There was no suggestion that Dr Lennan had committed any other offences at other times, there was no question of seduction or abuse of his position as an officer, and to all intents and purposes these acts were committed by consenting adults in private Mr Taylor read a medical report which stated that treatment should allow Dr Lennan to control his impulse

The Chairman announced that the committee took a grave view of Dr Lennan's convictions, which they regarded as deplorable in a medical practitioner, but were prepared nevertheless to take into consideration the testimonials and representations submitted on his behalf They would postpone judgment for two years, but would expect him to appear before them at the end of one year

ADDICTION TO DRUGS

The committee had two practitioners before them who had been taking pethidine

John Galbraith Mackay Anderson, registered as of Braddons Hill House, Torquay, Devon, L M S S A, through his counsel, Mr E B McLellan, instructed by Messrs Le Brasseur and Oakley, solicitors to the Medical Protection Society, admitted a series of convictions, of which the latest was last February, when he received concurrent sentences of six months' imprisonment for driving a motor-car when under the influence of drink or drug

Mr McLellan said that as a medical student Dr Anderson had had prescribed for him substantial doses of pethidine, which relieved his asthma but laid the foundation for the addiction he had since acquired He did struggle against this, but once in a way he took the drug, and that made him more open to the influence of alcohol In 1956 he had entered hospital as a voluntary patient, but afterwards, as a locum tenens, he had had access to drugs, and their availability triggered off the addiction When he left prison he would like to enter a home for further treatment

The committee directed that Dr Anderson's name be removed from the Register This is subject to appeal

John Adams MacDougall, registered as of 34, Liberton Brae, Edinburgh 9, M B Glasg (1934), had been found guilty at Edinburgh Sheriff Court in January of procuring dangerous drugs contrary to the Dangerous Drugs Regulations In a letter he said that his psychiatrist advised him in future to avoid general medicine and general practice Since leaving hospital last March he has been working in a garage repairing motor-cars, which his psychiatrist described as "an essential part of rehabilitation from his pathological condition" The committee postponed judgment for a year

A practitioner who had morphine suppositories for a fistula later became addicted to morphine He is *James Joseph O'Reilly*, registered as of 4, Danygraig Road, Risca, Monmouthshire, M B N U I (1925), who admitted a conviction under the Dangerous Drugs Act

Mr Widgery stated that Dr O'Reilly had pleaded guilty to a number of other charges under the Dangerous Drugs Regulations, in respect of which he was put on probation for two years, with a condition that he should spend six months as an inpatient and six as an outpatient (There had been an earlier probation order, in 1954) He was at present an inpatient, and his authority had not been withdrawn by the Home Office Dr O'Reilly was represented by Mr Taylor on behalf of the Medical and Dental Defence Union of Scotland

Dr John Weir Crichton, of Chepstow, said that his junior partner and he, though not needing an assistant, were willing to take Dr O'Reilly in "if he comes to me he will have work to do and companionship" Both Dr Crichton and Dr O'Reilly would prefer that his authority should be withdrawn

The committee postponed judgment for a year

FAMILY PLANNING

AT the annual meeting of the Family Planning Association, held in London on June 7, SIR RUSSELL BRAIN, the president, surveyed the family-planning movement as it affected world population and its operation in this country

Speaking of the three scientific revolutions—in health, industry, and agriculture—Sir Russell said that, though there might be no inherent reason why the human race should not in the long run be able to solve its population problems, the complexity of the issue involved did not encourage anyone

"to think that the task of increasing the food supplies of the world until every human being has enough to eat can be carried out quickly enough to make any practical difference for a long time and we must remember that an inadequate diet means not merely being hungry or having insufficient energy for physical requirements, let alone the activity of the mind, but it often means in practice suffering from one or more of the various deficiency diseases which result from an inadequate or an unbalanced diet We are forced to the conclusion, therefore, that even if mankind, especially those in nations with power and authority, can be made aware of the problem and stimulated to seek its solution, and—a further big if—if the nations of the world can achieve a greater degree of international cooperation for the welfare of humanity than they have succeeded in achieving in most matters in the past, only the control of population growth can shorten the time which it must take for food supplies to catch up with the needs of humanity"

These facts, said Sir Russell, are forcing upon many people a reconsideration of the whole question of conception control He referred to the Warren report (*The Family in Contemporary Society*) prepared by the Church of England Moral Welfare Council for the forthcoming Lambeth Conference at the behest of the Archbishop of Canterbury As the report pointed out, there was nothing Christian in the suggestion that so-called "natural checks" should be left to exercise their own restraint upon population—that men and women and infants should be left to die and pestilence should walk unchecked, or war or abortion take their toll Sir Russell went on

"I should like to say, if I may, how encouraging it is not only to find a group of religious people prepared to examine this question afresh, but also recognising that it needs to be examined in the light of all the new knowledge which biology and psychology can throw upon it, recognising moreover that it raises questions of great difficulty in which there is room for more than one opinion"

Commenting on the historical progress in the attitude of the Church of England and other religious bodies, Sir Russell said

"It is odd that many of those who take the highest possible view of man should insist on regarding his sexual life from the lowest standpoint—that is to say, as justifiable only in terms of a biological activity which he shares with animals, namely its reproductive function Surely there is by now ample evidence in many spheres besides the sexual of how much man owes to his ability to transmute what are basically physical activities into embodiments of spiritual values It is the recognition of this which gives the Warren report such outstanding importance"

Turning to the work of the Family Planning Association in this country Sir Russell said

"But the needs of the world at large should not and do not compete with our responsibilities at home, and here we face a growing demand for our help I believe that we have a particularly valuable contribution to make to medical education of which the students unfortunately are often more aware than their teachers Why is this so important? Because family planning has come to stand for a positive ideal People have come to us not only for advice about spacing their children but because they need treatment for infertility, and because of physiological difficulties in their married lives and the psychological difficulties which are apt to spring from them Family-planning clinics, therefore, are making a most valuable contribution to the happiness and stability of married life All medical students should have the opportunity of learning how they can help their future patients in these matters, and that calls for organised and coordinated teaching in which the gynæcologist, the genito-urinary surgeon, and endocrinologist, and the psychiatrist should work together"

AWARD TO DR BAKER

Dr A S Parkes, representing the Oliver Bird Trust, presented to Dr J R Baker a special Oliver Bird medal for his contribution to research in contraception when he was associated with the Birth Control Investigation Committee Dr Parkes said the experiments Dr Baker undertook at that time were the first of their kind in a recognised laboratory in this country, and he was responsible for discovering the remarkable spermicidal powers of phenylmercuric acetate

NEEDS OF THE TEACHING HOSPITALS

Sir **Harry Platt**, at the annual meeting of the Sheffield United Hospitals on April 23, pointed out that medical science cannot stand still Diagnosis and treatment must be continuously advancing both in accuracy and in safety The "precision tools" of the laboratories, on which the practice of modern medicine is coming more and more to rely, are increasing in number and complexity "Thus we see the growing edge of knowledge on which the leading hospitals stand They cannot retreat If they are to go forward with confidence and enthusiasm they must be reassured that the sinews of war will not be withheld from them "

In the early days of the National Health Service it was hoped that the patching up of obsolescent structures would be a temporary affair, and that the epidemic of new hospital construction which has swept the North American Continent, Scandinavia, Switzerland, and more recently France and Germany, would spread to Great Britain "This has not happened, and we have been compelled to contemplate another long period practising 20th-century medicine in 19th-century structures" Despite physical and financial handicaps, British medicine so far retains a position of leadership, but a sense of frustration prolonged indefinitely must in the end handicap progress by limiting the freedom to experiment which is the lifeblood of medical science

Can we, Sir Harry asked, during the next ten years expect to see released from central Government funds, year by year, sums which will enable us both to remedy the physical defects in our hospital services and to provide for the ever-expanding needs of scientific medicine? It is estimated that for 1958–59 the gross expenditure on health services will be £736 million, of which £421 million will go to the hospitals "Will £421 million give us all that we need for our hospitals? It seems unlikely If this sum or its inflated equivalent is to represent a 'squeeze in perpetuity', what then? The difficult problem of deciding on priorities within scanty budgets will continue to dominate the picture" But there is a time-limit to the enjoyment of such austerities The Minister of Health has suggested that the upgrading of the non-teaching hospitals is an important priority "This may be good news for regional hospital boards but not so good for boards of governors, and for the universities, if they feel, as they should, an acute sense of responsibility for the structural quality of the teaching hospitals as apart from their staffs "

"We therefore face what to me is an inescapable conclusion—that for their special requirements in the future the hospitals must not only be set free, but must be encouraged, to seek additional sources of finance outside the central Government budgets of the N H S For the teaching hospitals this should be a welcome return to old practices and in keeping with their long heritage In appeals to the community, to industry, and to philanthropic individuals they would thus behave as do the universities Such efforts might enable us to see in the space of a few years several new teaching hospitals in this country, each embodying completely novel features—i e, hospitals designed specially for the purpose of teaching the undergraduate"

Addressing the meeting earlier, Alderman A Ballard, chairman of the Sheffield board of governors, quoted the remark of the House of Commons' Select Committee on Supplies that "until the standards of non-teaching hospitals reach a significantly higher level, the allocation of development and improvement money to teaching hospitals should continue to be strictly limited" It would be absurd, he said, for the teaching hospitals virtually to mark time until every other hospital caught up with them On the industrial front in Sheffield he had been seeing how the challenge of this age of *science and automation is being met* "There could easily be a catastrophic fall in our standard of living if we did not keep in the forefront in these matters It is equally true that we should fall behind in the field of medicine, surgery, nursing, and so on if the teaching hospitals had to await the raising of general standards"

Medicine and the Law

On the Soup

A WOMAN teacher of the blind, while visiting a hospital in the course of her duties, slipped at the foot of a flight of stairs on a patch of soup which had spilled from a food trolley while an orderly was pushing it to the wards She suffered severe leg injuries, and brought an action against the hospital management committee for breach of the duty owed by the occupier of premises to her as an invitee

The law as laid down in 1866 is that such a visitor is entitled to expect that the occupier will use reasonable care to prevent damage from an unusual danger of which he knows or ought to know The management committee denied negligence They admitted that soup had been spilled At the trial the orderly said that the soup, carried in a container, spilled about once or twice a week, that on this occasion, as soon as he had discovered it when he pushed the trolley aside he had gone to get a cloth to mop it up, and that the accident had happened during the 30 seconds that he was absent

The trial judge found that there had been no negligence The plaintiff appealed, and the Court of Appeal dismissed her appeal

Lord Justice **Hodson** said that the submission for the plaintiff was that the orderly ought, before going for the cloth, to have taken the obvious precaution of putting the trolley over the soup in order to comply with the legal duty owed to an invitee as laid down in Indermaur *v* Dames in 1866 The first question was whether there was here a danger, and in negligence cases it was relevant to consider the extent of the danger This was not a very acute danger, for the risk of slipping on floors was always present, and spilling a little soup occasionally could not properly be described as negligence Thus the question was whether the orderly's failure to take the obvious precaution of covering the patch with the trolley while he went to fetch the cloth could be treated as negligence If the soup had been left there a long time there would have been no doubt about the negligence But here, as soon as it was discovered, the orderly, instead of doing what the ideal citizen would do by putting the trolley over the soup, had gone straight off to get a cloth His Lordship did not think that he had fallen below the standard of care of the ordinary reasonable man The chances of accident were not very high The appeal should be dismissed

Lord Justice **Morris** said that he had felt difficulty over the case, for there was much to be said for the view that the reasonable man would have thought of the simple step of putting the trolley back over the soup once he knew it had been spilled at a place where people passed up and down fairly often and where anyone descending the stairs would put his foot But the question was one of fact and degree, and as his Lordship's brethren thought that the trial judge's conclusion was correct he would not dissent from their judgments

Lord Justice **Sellers** said that to treat this little spill of soup as if it were a hole or something of such obvious danger that it required protection would be wrong He accepted the trial judge's judgment without criticism

GRIFFITH *v* SALFORD HOSPITAL MANAGEMENT COMMITTEE *Court of Appeal* Lord Justice Hodson Lord Justice Morris, and Lord Justice Sellers June 3, 1958 Counsel and solicitors C T B Leigh (I Edwin Monks & Co, Manchester), A K Hollings (Bower Cotton & Bower for Slater Heelis & Co, Manchester)

Congresses

GASTROENTEROLOGY

The World Congress of Gastroenterology, held in Washington, D C, on May 25-31, under the chairmanship of Dr H L Bockus (Philadelphia), was attended by some 1700 delegates from 51 countries Symposium panel discussions covered five topics—peptic ulcer, malabsorption syndromes, nutrition and its effect on the liver and pancreas, intestinal infections and infestations, and gastric carcinoma—and many other original contributions covered other aspects of gastroenterology

Peptic Ulcer

Epidemiological aspects of peptic ulcer in Great Britain were described by Dr F Avery Jones, who had compared the clinical incidence of peptic ulcer after interviewing 6047 members of the public with ulcer occurrence in a survey of 7722 necropsies from nine different medical centres in the country An almost exactly similar estimate of ulcer frequency was obtained if incidental ulcers discovered in patients dying in hospital from causes other than ulcer were compared with the clinical series, while numbers of active ulcers demonstrated at necropsy closely paralleled the percentage of patients having recent clinical symptoms

In the same forward-planned concurrent necropsy survey in 1956, Dr Geoffrey Watkinson was able to demonstrate a significantly increased prevalence of most types of chronic ulcer in men and to a lesser extent in women in northern as compared with southern towns in England and Scotland where ulcers caused more deaths and were found by chance significantly more often Ulcer frequency was highest in York, Leeds, and Glasgow and lowest in Oxford and London Whether these clearcut differences reflected differing dietary, occupational, or smoking habits was not determined

Regional differences could even be demonstrated in the same district, as was shown by Dr C N Pulvertaft, who in a population survey conducted in York between 1952 and 1956 demonstrated that both gastric and duodenal ulcer, in both men and women, was commoner in the city-dweller than in the countryman from the surrounding rural area These differences did not seem to be due to social status, age differences, or smoking habits, but it was found that the sugar consumption of the ulcer patient was significantly greater than that of controls in both areas, and significantly greater in town than in country Whether this represented a causal or aggravating factor had not been established Ulcer frequency in Great Britain could be correlated with social class, lower income groups containing a significant excess of gastric-ulcer patients Familial factors seemed of importance in that ulcers occured two to three times more often in the relatives of ulcer patients—an aspect also stressed by Dr J J Dubarry (France)

Genetic factors in relation to A B O blood-groups seemed to determine ulcer site in the patient with chronic gastric ulcer, in 1500 ulcer patients analysed by Dr B P Billington (Australia), ulcers in the area occupied by the fundic glands were associated with blood-group O, whereas ulcers in the prepyloric area contained a significant excess of group-A individuals Duodenal ulcers were more likely to occur in responsible executives, and agricultural workers seemed least likely to be affected Studies undertaken by Jones and Doll incriminated smoking as a possible factor in ulcer occurrence and in delayed healing When the smoking habits of ulcer patients and controls were compared, there were substantially smaller proportions of non-smokers or of very light smokers among ulcer patients of each sex, proportions being even smaller in gastric-ulcer patients The rate of healing of gastric ulcers could be significantly accelerated if smoking was stopped

Surprisingly similar data on ulcer prevalence and disease pattern in America were presented by Dr S M Jordan, and the frequency and clinical features of ulcer in Austria (Dr R Boller), Mexico (Dr J M De La Vega), Brazil (Dr G Siffert), Switzerland (Dr B Wissmer), India (Dr P Raghavan), Japan (Dr T Kurokawa), and the Middle East (Dr J Kleeberg [Israel] and Dr D Munzer [Syria]) were enumerated Ulcer was revealed as widespread throughout the world, the disease pattern varying from place to place, in age and sex distribution, in the types of ulcer observed, and in the type of complications In this respect a report on gastroduodenal ulcer at high altitudes in the Peruvian Andes by Dr G Garrido-Klinge was of particular interest In a population of 17,500 miners working at an altitude of 12,000–16,000 feet, ulcer recurrence showed a low overall frequency of 0 7%, an increased tendency to hæmorrhage, which occurred in 53% of all ulcer patients, and an excessive preponderance of gastric ulcer, which occurred twenty-six times more commonly than did duodenal Ulcer frequency in nearby Lima at sea-level conformed more nearly to other parts of the world where the usual excess of duodenal ulcer was observed Circulatory changes and plethora induced by the high altitude were thought to be the likely explanation for this unusual pattern

Sudden changes in dietary habits were thought by Dr A Lambling to explain the increase in the prevalence of gastric ulcer in France in 1942 and 1943, when rations, particularly of protein, were at their lowest Resumption of normal feeding habits after the war led to increases in duodenal ulcer, the disease reverting to the pattern observed before the war Dr Geraldo Siffert did not feel that the "awful lot of coffee in Brazil" had affected ulcer frequency in that country

Possible hormonal factors in ulcer production were discussed by Dr S J Gray (U S A) The role of the hypothalamic-pituitary-adrenal mechanism was evaluated in relation to the peptic-ulcer reaction Steroids were shown to increase gastric acid and peptic output, to increase blood and urinary pepsinogen, to decrease the mucus protective barrier, and to impair tissue healing over a period of three to four weeks, all of which might determine ulcer formation The rarity of ulcer and the low urinary pepsinogen levels in hypofunction of adrenals or pituitary were stressed, but ulcers could be induced in these patients after steroid therapy While the urinary output of ketosteroids did not differ from normal in the ulcer patient, submaximal stimulation by corticotrophin in these patients induced a significantly greater response than in the normal, suggesting that they reacted excessively to stress

The relation of pancreatic endocrine function to peptic ulcer was elegantly described by Dr D W Elliot and Dr R M Zollinger (U S A) 75 examples of the syndrome described by these workers in 1955 had now been reported The syndrome comprised severely progressive peptic ulceration, which did not respond to surgical, medical, and radiation therapy, and gross gastric hypersecretion associated with a non-secreting β-cell adenoma of the pancreas A visible tumour in the pancreas should be locally excised and total gastrectomy performed, multiple adenomas or occult functioning metastases in a gland of normal size might make it necessary to do a partial or total pancreatectomy in cases where adequate surgery had failed to prevent ulcer

While much of the mosaic comprising the pattern of ulcer disease throughout the world was filled in, and many ætiological factors were identified, the final cause of peptic ulcer remains unclear, but it was felt that widespread epidemiological surveys would help to identify the elusive final causal factors

Malabsorption States

Causal factors in the production of the malabsorbative state were classified by Prof A C **Frazer** (Britain) as (1) conditions without enteropathy where a lack of pancreatic secretion determined defective intraluminal phase of absorption, and (2) conditions with enteropathy where the change might be induced by gluten intolerance, by folic-acid deficiency, by changes in intestinal flora, or by organic changes in the intestinal tract or wall or mesentery In gluten-induced enteropathy dietary wheat caused the syndrome, which disappeared on a wheat-gluten-free regime, only to relapse when gluten was reintroduced While acid hydrolysis and deamidation removed the deleterious effects of the compound, these persisted after peptic and tryptic digestion, and wheat gliadin and an autoclaved peptide gluten fraction would both induce the syndrome

The importance of wheat sensitivity was also stressed by Dr D H **Anderson** (U S A) and by Dr H A **Weijers** and Dr J H **Van de Kamer** (Netherlands), the latter workers had shown that patients with steatorrhœa reacted to the administration of wheat gliadin by an abnormal rise in blood-glutamine level Folic-acid deficiency was an early and prominent feature of tropical sprue, which induced temporary reversible changes in the intestine, in many patients correction of the deficiency induced permanent remission, but in others severe steatorrhœa persisted Changes in intestinal flora might determine some of the characteristics of the stools in the malabsorption syndrome, in view of the frequent dramatic responses to antibacterial therapy in patients with tropical sprue

This factor seems of little importance in the cœliac syndrome, as was beautifully demonstrated by Dr **Charlotte** M **Anderson** (Australia), who found no quantitative differences in bacterial flora in specimens obtained by intubation of the small intestine between normal children and those with malabsorption and steatorrhœa Rancid dietary fats ingested by Service personnel in Hong Kong were thought to have initiated the sprue syndrome in previously healthy young adults on a few occasions Organic enteropathies induced malabsorption in regional ileitis, Whipple's disease, scleroderma, gastrocolic fistula, and the anastomotic and loop syndrome When these various types of syndrome had been identified, few cases remained for which the term " idiopathic steatorrhœa " might be retained

The clinical behaviour of sprue in the United States was ably described by Dr E E **Wallaeger** on the basis of 400 patients seen at the Mayo Clinic since 1930 The pattern of tropical sprue in Cuba appeared to have become strikingly milder when the type of disease seen between 1927 and 1937, when a florid glosso-entero-anæmic diarrhœal disease occurred, was compared with that in the past decade, in which an incomplete mild frustrated type of disease was observed This was thought by Dr F **Milanes** (Cuba) to be due to improved individual constitutional resistance coinciding with more adequate dietary intake

One of the most significant advances in this field has been the confirmation that temporary or permanent structural changes in the intestinal mucosa frequently cause or complicate the malabsorption state This change, described by Paulley in 1952 and 1954 in fresh operative specimens, has been confirmed and its significance reassessed by the development of a small intestinal-biopsy instrument by Dr **Margot Shiner**, who in conjunction with Dr I **Doniach** (Britain) described the application of this technique to patients with non-tropical sprue. Partial or complete atrophy of the intestinal villi, with degenerative changes in the surface columnar epithelial layer and cellular infiltration, was observed This change, which inevitably accompanied idiopathic steatorrhœa and the cœliac syndrome, was irreversible even though therapy induced clinical remission The changes did not occur in symptomatic steatorrhœa complicating gastrectomy or pancreatic disease In steatorrhæas complicating the folic-acid deficiency of tropical sprue or in megaloblastic anæmia, structural changes in the intestinal mucosa were reversible by appropriate therapy

Similar changes in the distal small bowel were thought to form the basis of cyanocobalamin and folic-acid deficiency in idiopathic steatorrhoea in combined hæmatological and absorbative studies undertaken by Dr D L **Mollin** (Britain) It was now possible to demonstrate Whipple's disease by this method in place of laparotomy, which was formerly required

A perhaps more convenient device for intestinal biopsy had been developed by Dr W H **Crosby** (U S A) This consisted of a metal capsule 11 × 17 mm containing a rotating spring-activated knife which was triggered by suction when the intestinal mucosa completely occluded the biopsy orifice The capsule was held captive on a fine polyethylene catheter which served both to apply suction and to retrieve the capsule when the biopsy specimen had been taken This capsule had the advantage of being easy to swallow and of penetrating deeper into the small bowel than had been previously possible It had the disadvantage that only a single biopsy specimen could be taken, but multiple capsules could be swallowed in tandem and simultaneous biopsy specimens obtained at different levels

Several papers described the use of isotope-labelled fats, fatty acids, and protein in patients with malabsorbative states (Dr D **Sandweiss** [U S A], Dr C **Wilmer Wirts** [U S A]) This test emerged as a valuable one in the diagnosis of steatorrhœa and its distinction from pancreatic disorders

In an intensive study of normal and abnormal fat absorption by Dr R **Blomstrand** (Sweden) ^{14}C-labelled fatty acids had been fed to patients and its content simultaneously compared, in intraluminal specimens obtained by intubation, in lipids of the thoracic-duct lymph cannulated by a new technique in man and in the fæcal fats Differences in the absorption of saturated and unsaturated fatty acids were demonstrated, furthermore it was found that a part of the unabsorbed oleic acid had been hydrogenated in its passage through the alimentary tract. Diet and synthesis by intestinal microorganisms seemed quantitatively the most important sources of fæcal fatty acid

The last significant advance in this field was the introduction by Dicke in 1950 of the gluten-free diet for the treatment of the sprue syndrome While its value for cœliac disease was soon demonstrated, its value in the adult form of idiopathic steatorrhœa has only recently been established Dr J M French (Britain) discussed his experiences with the gluten-free diet in adult idiopathic steatorrhœa In 31 of 44 patients remissions had followed its use, these were characterised by weight gain, well-being, control of diarrhœa, and a return of fæcal fats and blood findings to normal Reasons for failure were hard to identify and were unrelated to sex differences, to age or duration of disease, or to previous cœliac disease. As the response to the diet was often slow, taking thirty to a hundred days, therapy should be continued for at least six months before failure was admitted Avitaminosis, anæmia, and the presence of a complicating bacterial enteritis might be further causes of failure Although varied opinions were expressed as to the merits of the diet in relation to fat restriction and to steroids, the diet seemed to be internationally accepted as a significant advance in the therapy of the sprue syndrome

Regarding the steatorrhœa complicating small-bowel resection in man, Dr M H Kalser and his co-workers (U S A) found that in patients in whom massive resections (8–10 feet) had been performed, where jejunum had been anastomosed to ileum only minimal steatorrhœa ensued, but in all cases where terminal ileum had been removed and anastomosed to colon severe steatorrhœa was observed Resections of 4–5 feet of small bowel did not cause steatorrhœa, regardless of the site of resection or type of anastomosis These findings emphasised the importance of terminal ileum and ileocæcal valve in normal fat and protein assimilation

The fact that in most instances the term " gluten-induced enteropathy " can be substituted for the term " idiopathic steatorrhœa " is a measure of the extent to which knowledge has advanced in the past decade, in which the causal factors, pathology, and effective treatment have been largely identified

Influence of Nutrition on Liver and Pancreas

The researches on the effects of lipotropic factors on liver-disease in Sir Charles Best's laboratory were reviewed by Dr G Wilgram (Canada) Although choline deficiency induced in primates fatty accumulation in the liver closely resembling kwashiorkor in man, it had not been found practicable to perform the crucial experiment which would implicate choline as the likely cause of the condition This would involve the administration of a diet with a borderline protein content, sufficient in calories, and low in choline, and it had not been found possible to devise a suitable diet for this purpose

In France Prof J Caroli has established a definite statistical relationship between the average individual consumption of alcohol and the development of cirrhosis Mortality due to cirrhosis fell by half in the period of the German occupation when alcohol was scarce A controlled investigation into the relation of individual alcohol intake to cirrhosis in three French towns revealed that wine consumption under 1 litre daily never induced cirrhosis, whereas an intake of over 2 litres daily invariably did so The fact that 1–2 litres daily induced symptoms in 40% of subjects suggested that some individual susceptibility was necessary for the development of the condition Deficient nutrition and diet were often contributory, and women seemed more likely than were men to develop symptoms Alcohol administered experimentally to animals had not consistently induced fatty change

Dr C S Davidson had found that in Boston, Mass , hepatic cirrhosis in men of 55–64 was the fourth commonest cause of death When the clinical pattern of cirrhosis in Boston, which was due most often to alcohol, was compared to that in London, England, where alcohol was rarely a cause, important differences emerged Predominantly alcoholic cirrhosis was associated with a poor dietary intake, vitamin deficiencies, jaundice, and symptoms of alcohol withdrawal were common Dupuytren's contracture and parotid enlargement were often seen, anæmia was uncommon but leucocytosis was usual The disease ran a fluctuant course but remained potentially reversible for a long time before hepatocellular failure supervened In non-alcoholic cirrhosis, by contrast, appetite was usually maintained, jaundice was rare, and a progressive course associated with anæmia and leucopenia was the rule Chances of recovery were small and the symptoms of portal hypertension were more prominent

The relation of primary liver cancer to underlying nutritional factors was described by Dr C Berman (South Africa) This form of malignant disease was one of the rarest forms of carcinoma in Europe and the Western hemisphere It was remarkably frequent among the native inhabitants of Africa and certain parts of Asia, indeed in the Bantu races and among the Indonesians it was the commonest form of internal cancer While the ultimate cause of liver cancer was unknown, it was becoming increasingly apparent that nutritional and environmental factors were important in its production Known carcinogens such as butter-yellow would readily induce liver cancer in laboratory animals, this was usually preceded by massive fatty necrosis of the liver, cirrhosis, and liver damage, and the frequency of its production could be modified by diet Indeed, in some animals liver cancer had been induced by deficient diet alone In man it seemed likely that prolonged or cyclical dietary inadequacy, so prevalent in Africa and Asia, frequently produced hepatic fibrotic lesions associated with primary liver cancer It was also possible that hepatotoxic or carcinogenic agents might be present in the food or beverages of the afflicted populations

Epidemiological aspects of acute hepatitis in Chile were described by Dr H Ducci While outbreaks of infective hepatitis in children were common in Chile, secondary infection in the adult was rare This, in conjunction with abnormal liver-function tests in apparently normal individuals, suggested that many of these patients must have had subclinical attacks of the disease in childhood, and that the majority of cases in adults were examples of inoculation hepatitis Nutrition did not seem to play a part in the spread or severity of the attacks of hepatitis

Changes in the liver and pancreas in kwashiorkor as observed in Guatemala were described by Dr N **Scrimshaw** Fat was deposited initially in the peripheral parts of the hepatic lobules, and later throughout the whole parenchyma reticulin proliferated While with appropriate therapy fatty deposits would disappear in seven to twenty-one days, reticulin proliferation persisted Pancreatic fibrosis with atrophy of the acini and collapse of the reticulin were not uncommon accompaniments of the disease, the pancreatic islets being spared until the terminal stages These pathological changes were accompanied by evidence of functional pancreatic insufficiency Although associated parasitic and dysenteric infections occurred in patients with kwashiorkor, these infections were not more prevalent than in the general child population and did not seem to be a causal factor in the production of the disease

The effects of chronic malnutrition on liver disease in Mexico and in the West Indies were reported by Dr B **Sepulveda** and Dr S **Zubian** (Mexico) and Dr J C **Waterlow** (Jamaica) Dr Waterlow had studied the behaviour of the liver enzymes in deficiency states Only cholinesterase seemed to be affected in malnutrition, levels of transaminase and dehydrogenases remaining normal

Nutritional liver and pancreatic disease in Australia was described by Dr I J **Wood** In Melbourne, although malnutrition was uncommon, it was detected in a third of all patients attending a gastrointestinal clinic Alcoholism, organic disease of the gastrointestinal tract, food fats, and psychiatric disturbances were the common causes of the deficiency Dietary inadequacies induced fatty and later cirrhotic changes, which remained reversible for long periods before hepatic coma developed Arginine seemed promising in the treatment of hepatic coma Pancreatic disease was produced when malnutrition was associated with alcoholism, and this combination had been the cause in 17 out of 90 cases of acute or chronic pancreatitis Other common causes of pancreatitis were mumps, systemic vascular disease, gallstones, hyperlipæmia, pregnancy, and hæmochromatosis Although the incidence of parasitic disease, particularly roundworms, was high it seemed unlikely that these contributed to the production of the pancreatic or liver lesions

While this symposium produced valuable information on liver disease throughout the world, much still remains to be identified—particularly the enzymatic changes in the liver cells which initiate the structural damage

Intestinal Infections and Infestations

Perhaps the most important fact that emerged from this symposium was the uncertainty as to the significance of pathogenic organisms and parasites when found in the bowel or stool

Infection

Dr **Erwin Neter** (U S A) emphasised that mere isolation of *Escherichia coli* from the fæces of children did not prove that diarrhœa was due to this organism, special serotypes—notably O 111 B 4, O 55 B 5, and O 127 B 7—could be incriminated since they were found in infants with enteritis, were rarely present in health, and would produce disease if fed to volunteers, an enterobacterial hæmagglutination test revealed antibody formation in infections of this nature, which could be controlled by neomycin Dr Neter had seen a case of diarrhœa infested with shigella and *Esch coli* which antibody reactions proved to be due to the shigella He went on to emphasise the possibility that viruses of the Echo and Coxsackie groups might be the underlying cause in some epidemics of diarrhœa in the newborn

Prof **Nanna Svartz** (Sweden), though considering ulcerative colitis to be infective in origin, did not regard dysenteric organisms, and in particular shigella, as a cause, and suggested that when these organisms had been associated with the disease, as in Felsen's series, they might have been secondary invaders She did, however, believe that an attack of dysentery could so sensitise the colon that it could later become vulnerable to its normal flora, which increase in number and virulence following dysentery

Dr **Joan Taylor** (Britain) held that the villain of the piece remains undetected in a large proportion of diarrhœal diseases, and that the serotypes of *Esch coli*, O 26, O 55, and O 111, like the poor, were always with us, and were pathogenic the world over, whereas O 127 waxed and O 128 waned in their pathogenicity, forming with others (O 117, O 86) a group only intermittently capable of causing disease No differentiation could be made on clinical grounds alone between coliform, salmonella, and shigella infections, all of which had become milder, classification could only be made bacteriologically In Britain shigella infection was almost always due to *Sh sonnei*, there being 43,000 cases each year, and few were due to *Sh flexneri*, these being in mental institutions Each year there were 6000 cases due to salmonella infection, in 75% of which the organism was *Salmonella typhimurium*, this gained access in protein foods imported for man and animals

Dr W H **Dearing** (U S A) doubted whether *Staphylococcus aureus* could be held to account for all cases of pseudomembranous enterocolitis, since of 19 deaths from this disease in 11 cases no staphylococcus could be found in the bowel at the time of death, contrariwise in 4 necropsies in patients with staphylococcal enteritis who died of other causes, no ulcerative or pseudomembranous lesions were observed in the intestines

Infestation

The mere presence of *Entamœba histolytica* in the stool must not be taken as evidence of clinical amœbiasis Dr R **Elsdon-Dew** (South Africa) pointed out that in Britain, although 10% of the population were infested with *E histolytica*, amœbiasis was virtually unseen, whereas in Durban the disease was rife though the prevalence of infestation was no higher The manifestation of disease in the presence of the parasite was in some way associated with urbanisation and industrialisation, for the incidence in Coloured South Africans was higher in towns Diet appeared important, the wheat-fed being more susceptible than those eating rice, the rural Negro on moving to town changed his diet to one based on high-extraction wheat flour and sugary drinks This caused a change in intestinal bacterial flora and permitted the amœbæ already present to become parasitic—a situation which could be reversed by attacking the bacteria with antibiotics Dr Elsdon-Dew pointed out that symptoms were commonly ascribed to amœbiasis in error, simply because *E histolytica* was found in the stools He asked Should antiamœbic treatment be given whenever the protozoan is found?, and in the panel discussion which followed it became clear that others are asking the same question

Dr R Armas Crus (Chile) raised the problem of treatment Evaluation was difficult both clinically, since many patients had no symptoms, and from the stools, since the parasites might disappear spontaneously from the stools and reappear later In a controlled investigation into the efficacy of various forms of antiamœbic therapy the control placebo had proved as effective as the best treatment, causing the trophozoites to disappear in 72 7%

Dr M M Brooke (U S A) was concerned with the difficulties of demonstrating *E histolytica*, particularly in the non-dysenteric cases and carriers when the distinctive trophozoites are absent Stool examinations must include a careful search for cysts He outlined methods of collection and examination and emphasised that the reliability of a laboratory depended on the skill of the microscopist Serological and complement fixation tests were not of value

In Cuba, said Dr J G Basnuevo, about 5% of people are infested with *E histolytica*, but there was considerable regional variation, the prevalence being inversely proportional to the density of the population White were more commonly infested than Coloured people, as were females than males, but liver abscess was far commoner in men than women and was usually seen between the ages of 30 and 50 (it had been observed under the age of 2)

Gastric Cancer

In this symposium emphasis was laid upon the need to detect the early cancerous and the precancerous lesions

Dr I S Ravdin (U S A) pointed out that only surgery could alter the course of the disease, and that a five-year-survival rate of 50% could be obtained in cases with no lymph-gland involvement. The outcome of operation depended more on cases being brought early to surgery than on the extensiveness of resection, indeed, total gastrectomy, in his opinion, was unsuitable At his clinic only 4% of patients submitted to palliative resection survived for five years, in contrast to 22% of those in whom resection was undertaken for cure These figures obtained after an overall operative mortality (death within thirty days) for resection of 2 8–5 7% in palliative operations and of 0 9% in curative operations He emphasised the persistent doubt regarding malignant change in benign gastric ulcers, and that X-ray evidence of healing in a gastric ulcer cannot be taken as evidence against malignancy

On the other hand, Dr W H Bachrach (U S A) in an original paper denied that there was good evidence that malignant ulcers had been observed radiologically to heal

Dr Leo Rigler (U S A) felt that the improvement in results to be expected from advances in surgical technique had now reached the limit, and it was incumbent on the radiologist to find means of disclosing cancer of the stomach at an early stage, indeed in an asymptomatic stage In a small series of 38 cases, 22 were revealed without symptoms and 16 were subsequently found to be node-free, 11 had mild symptoms with 3 node-free, and of 5 with frank symptoms all had node involvement It was therefore at the asymptomatic stage that surgery really had its chance to cure, and in 36 cases of this group in which resection was possible a 33% five-year-survival rate was achieved The task of universal routine check X-rays was too great to contemplate, but the problem could be approached by investigating those patients in whom cancer seemed especially likely to arise He had made a pilot study of 3510 patients who had either no or low gastric acid or addisonian anæmia, and compared them with 1098 controls with normal acid In the control group no cancer or polyp was revealed 36 (1%) of the 3168 patients with no acid had evidence of cancer and 80 had polyps, of the 271 with low acid, 2 had carcinoma and 2 polyps, and of the 71 with addisonian anæmia 4 had a growth and 6 polyps

The search for a chemical test to reveal gastric cancer continues, Dr Y Tazaki (Japan) has found an increase in serum-fibrinogen, but this is not specific Also from Japan came reports in original papers that the reducing power of gastric mucoprotein is increased in the presence of cancer together with an increase of amino-acid nitrogen, of a cancer "toxin" which on injection into mice decreases the liver-catalase (Dr Hachiro Sato), and of a complex mucoprotein or polysaccharide extracted from gastric juice in cancer patients which on injection into rabbits causes a fall in erythrocyte numbers (Dr Kaichiro Ogura)

Dr J Clemmesen (Denmark) pointed out that gastric carcinoma comprised about 20% of all cancers in England and the U S A , 30% in Denmark and most European countries, and 40% in the rest of Scandinavia In Denmark, as in England, size of income was inversely related to incidence of gastric cancer

Dr J Maisin (Belgium) suggested that certain foods might dispose to cancer, smoked foods in particular had a higher carcinogen content than other foods

The experimental induction of cancer in mice and rats by 20-methylcholanthrene 0 3 mg injected into the stomach wall was described by Dr H L Stewart (U S A) In rats gastric cancer seldom developed spontaneously, but the distribution in the stomach of experimentally induced tumours mimicked that in man

Ulcerative Colitis

Dr R A Sifre (Puerto Rico) described 81 cases of ulcerative colitis seen over a sixteen-year period Though the condition was less common in Puerto Rico than in temperate countries its natural history and complication-rate followed the usual pattern. No ætiological relation had been found between bacillary or amœbic dysentery and ulcerative colitis, though parasites had been found incidentally in the stools of 22 cases

Dr S C Truelove (Britain) assessed the therapeutic value of hydrocortisone applied rectally in ulcerative colitis Remission had followed instillation of the alcohol-free derivative (60–120 mg each night) in 14 out of 21 courses, and of the water-soluble hemisuccinate compound (100 mg each night) in 11 out of 18 In a controlled trial the hemisuccinate was effective on 11 occasions out of 20 courses, in contrast to once out of 20 for the blank.

Dr M B Goldgraber (U S A) had studied the pathology of surgical specimens from 76 patients and 46 necropsies Neither cryptitis nor vasculitis was predominant, but infiltration with histiocytes and granuloma formation were noted—suggesting a hypersensitivity reaction

In England Now

A Running Commentary by Peripatetic Correspondents

MEDICAL friends of my own age (around 50) seem so comfortably situated—highly respected G P s, living in lovely big houses, driving around in shining motor-cars, they are so opulent and confident-looking They never spare a thought for me, a poor ex-Colonial forced by political pressures to hand in my chips before my pension could even earn income-tax Back in the mother country, cap in hand, I began to look for work General practice, hospital appointments, and so on are all closed doors to the likes of me—but I found a welcome waiting for me as an assistant medical officer of health

I grumbled a bit at my starting salary, but beggars can't be choosers I set to work with a will and I am gradually getting used to the pace of life in this country with its frequent stops for tea and general easyosiness The new job has its interests, but the rehabilitation process is painful

Many of the jobs I now have to do, in my former state I would have delegated to a junior African orderly

Last week, while crouching behind a blackboard examining one of the healthiest schoolboys I've seen for many a long day, the aura of the classroom brought to mind Dryden's long-forgotten words

He chose a mournful Muse
  Soft pity to infuse
He sung Darius great and good,
  By too severe a fate
Fallen, fallen, fallen, fallen
  Fallen from his high estate

But all is not black, I have a first-rate boss and spend the day with sagacious and kindly health visitors The breathtaking beauty of the countryside as spring leads into summer is worth the loss of £1000 a year On the home front, too, there are compensations—no wifely grumbles about " these awful boys ", and my children are living a more normal life, making better progress at school, and acquiring a decent accent

So all in all, don't pity me, I'll make out—and I'd rather live in Britain, these days, than anywhere else in the world

* * *

Regular peripatetic readers who heard some years ago of the first, and as yet only, peal on eight bells rung by doctors, may be interested to hear more about medical campanology The Medical Guild recently held its third annual meeting—and very successful it was We are a small, enthusiastic, and widely scattered society, we may not go from China to Peru, but we have members working both on Vancouver Island and in Korea —the latter happily on leave we were glad to see at the meeting Students and nurses also belong to the group, and we seem to have a strong attraction for obstetricians Perhaps our grand total of three consultant obstetricians means that something in common is needed for axis-traction and turning in the tenor?

Our gatherings always end with dinner and hand-bell ringing, we have amazed the residents at several country hotels by this after-dinner exercise I am glad to report that generally our efforts are well received, and have even been known to attract hardened televiewers On this occasion, however, the inn was small, and very full, so our " touches " took place on the village green, to the wonder of the lads of the village, and the annoyance of the birds coming home to roost

* * *

Twenty-five of us G P s assembled in the board room on Monday morning, warily eyeing each other, and diffidently fixing name-tabs to our lapels We had gathered for a week from all over England and Scotland to receive " refreshment "

The refresher-in-chief was an energetic Consultant Physician, impressively erudite We felt sympathy for his loyal attempts to smooth the rough edges of the surgeon's obiter dicta

It is some achievement to hold a score of G P s spellbound in the description of a disease of which only 15 cases have been treated This our Neurologist was able to do with an ease an control of the language which confirms my view that th specialty is the preserve of the intellectual élite of the professio

There was a retinue of other specialists—a studiously kee Orthopod, a bald Dermatologist who convinced us that " skins sometimes die and can sometimes be treated, and a somewha enthusiastic Pædiatrician contemptuous of the overfeedin bogy—" feed 'em till their eyes pop " The Plastics man "before" and "after" pictures were an impressive demonstratio of modern surgical art The local Chest Physician led a usef symposium His clinic, reminiscent of the South Bank, had a array of buttons and flashing lights and is presumably ru by automation

It was a case of " early to bed " all week The tilling an sowing of fallow cerebral convolutions was a tiring proces But the stimulant of a glass of sherry on the last evening was pleasant finishing touch to an enjoyable and useful week

* * *

In my endeavours to further the cause of science, I perfor incredibly complex tests on 24-hour collections of urin Recently a dear old lady handed in a $2^{1}/_{2}$-litre bottle full to th brim Such a collection naturally arouses suspicion, and whe I next saw her I raised the question of the completeness the collection She stonewalled all questions until at long la she said· " Indeed everything went into the bottle, in fa I had to empty the bottle out to get the last lot in! "

* * *

It was nice to return after thirty years It's true that Trin Street seems too narrow even for one-way traffic, but my wi got over the difficulty of the police No Parking notice outsi the Woad Pig Hotel, where we stayed, by knocking it over an parking on top of it Exercising my dining rights, I donne my gown and square—long known by the children as " Daddy thinking cap "—and strolled up Green Street to the Colleg only to find that mortar boards are obsolescent, which is pity when one is getting thin on top Most of the members the Senior Common Room were strangers, and I chatted to particularly nice young man, evidently a junior fellow I though until the butler opened the door, bowed to him and announce " Dinner is served, Master " It was pleasant to dine at th high table next to him, under the portrait of the Lord Protecto pleasanter still to sip port and madeira in the S C R afte wards, and be waited on by the young dons It was strange be addressed by them as " Sir ", instead of the other wa round At first I felt a little disconcerted Do I really lo as old as that? But no, it isn't the respect given to age, but learning, for I was wearing a doctor's gown and none of the has risen higher than M A

* * *

Thirty-six local schoolgirls were confined at St Dunstan's Churc Cheam, on Saturday by the Bishop of Woolwich —*Epsom and Ew* *Herald*, May 24, 1958

I agree in principle to closer cooperation between th Church and the Medical Profession, but surely this is carryin things a bit too far

* * *

IT STRIKES ME

A busless London is a pleasant sight,
  No big red monsters there to block the light
And as the crowds pass by with hurried feet
  They see the full perspective of the street,
While at the stopping places where of late
  Long rows of heavy buses used to wait
The passing car will offer you a lift
  —No payment asked—a very welcome gift

The traffic problem now seems to be solved—
  What's that you say? *The deadlock is resolved?*
The men going back to work? Oh tell me when?
  I shall be glad to see them back again

Letters to the Editor

THE DANGEROUS WATER-STERILISER

SIR,—Much publicity has been given to the efficiency and testing of autoclaves in operating-theatres, but attention has seldom been drawn to the water or lotion sterilisers Most outbreaks of theatre infections are due to bacteria which are easily killed even by an inefficient autoclave, and in three different outbreaks which I have investigated the infection was traced to the water sterilisers

These have several danger points They consist of a tank in which water is heated by a steam coil and cooled by a cold-water coil The water entering the tank is controlled by a screw tap and is drawn off through a similar tap The water level is indicated in a glass tube connected to the tank at top and bottom An air vent and safety valve is fixed to the tank and usually a cotton-wool filter is inserted into this After the water in the tank has boiled for half an hour it is considered sterile and is cooled, but I have often found coliform bacilli and cocci in it, which were killed at a temperature of 60°C in a few minutes The water must therefore be contaminated after boiling, and the possible ways of entry are

(1) The air vent The filter may be absent, dirty, or inefficient

(2) The safety valve. The seating may be worn, and dirty water may be drawn into the tank as it cools

(3) The cooling coil may be leaking

(4) The inlet valve may be leaking

(5) The outlet valve may be dirty

(6) The water-level gauge may be infected The water in this tube is not boiled with the main tank water and does in fact hardly get warm As water is withdrawn from the tank the contents of the level gauge mix with it freely

The first four faults are easily remedied, but difficult to spot I have seen a new installation in which the washers in every single valve were perished, but this was not noticed until a large number of postoperative infections had occurred

Faults (5) and (6) are most difficult to rectify The outlet tap may be sterilised by directing a jet of steam over it before use, and the water-level gauge can be emptied when the water is boiling and steam from the tank allowed to pass through it It is possible to produce sterile water in this way, but it is not absolutely safe and only a bottled supply of autoclaved water can be guaranteed to be sterile

PHYSICAL CHANGES IN THE PROLAPSED DISC

SIR,—In your annotation of June 7 you outline one of the difficulties in understanding disc disorders—namely, how to reconcile the theory that pain can be caused by swelling of the disc with the observed fact that at operation the protruded disc material is stringy and desiccated

If a practitioner is to reassure his patients by explanation he must be given a working hypothesis May I suggest the following scheme?

The normal internal turgor of the disc, as well as the episodes of abnormally high tension which I believe are the cause of lumbago, depend on the presence of a mucoprotein which has a powerful affinity for water The normal process of ageing is accompanied by desiccation of the nucleus which is presumably the result of physicochemical changes in the structure of the molecule of the mucoprotein The slow physicochemical change of normal senescence in the disc is symptomless and elderly patients are much less prone to a first attack of lumbago than are those in early middle age I suggest that a disc which is the site of acute lumbago in early middle age has gone through the physicochemical changes of senescence in a matter of days or weeks The molecular change is accompanied in its early stage by a raised affinity for water, and the swelling of the disc produces the pain and spasm characteristic of lumbago When the acute phase of the episode subsides, which is usually before the end of the third week, the contents of the disc are left in the condition of senescence This process may affect an isolated disc in an otherwise normal spine The process may cause complete degeneration of the disc, in which case the patient never has another attack of lumbago or sciatica Alternatively, the degeneration may be focal and sufficient normal mucoprotein may be left to cause further episodes of lumbago before the disc becomes finally and permanently inert

We now arrive at the concept of a disc sequestrum This is the result of focal degeneration and is the symptomless residue of a previous tension episode This is what is removed when we operate on a disc protrusion The popular idea of how this sequestrum is projected through the layers of the annulus is the simple mechanical explanation that it " slips out " or is forced out by injury This mechanism most certainly can occur, and it explains those disc protrusions which happen suddenly and without premonitory symptoms But many disc protrusions are ushered in by discomfort in the back before the full violence of the attack is precipitated by a trivial movement In these cases I believe that the sequestrum is pushed out of the disc by an episode of raised internal tension affecting the mucoprotein which is as yet undegenerate This theory explains those disc protrusions which subside with the passage of time, made tolerable by simple heat Those cases which do not subside have a disc sequestrum firmly lodged in the displaced position which has failed to retract when the internal tension of the nucleus has subsided

I should be interested to know whether biochemists or biophysicists can offer any objection to this simple creed

TREATMENT OF ASTHMA AND HAYFEVER BY HYPNOSIS

SIR,—The *argumentum ad hominem* has played a declining role in scientific controversy since its heyday during the Renaissance, when forensic skill could still make up for deficiencies in other respects Science is now a discipline in which impartial inquiry may be assumed as a matter of course, and it is agreed by all concerned that if observations are accurately made and experiments are well designed as well as being capable of repetition by other workers, then their scientific validity is quite independent of the temperament, motives, religious beliefs, taste, or any personal quality of the investigator, except perhaps his sagacity His work can only be criticised on these terms, and no scientific investigator worthy of the name places any reliance on persuading his opponent with rhetoric or on driving him from the field with invective, as President Conant so aptly puts it It is possible, therefore, if not certain that the failure to understand Dr Mason and Dr Black's contribution on my part, and I was not alone in this, may be elsewhere than in my alleged emotional attitude towards hypnotism

I am sorry to see, Sir, that you number yourself among the " statistics can prove anything " school, and I am sure that this view is partly based on a misconception of the use and function of statistical methods in biological research Such a misconception is well illustrated by a remark of Dr Mason and Dr Black in their letter of May 24 where they state " it often seems that almost any *result* (my italics) can be obtained

TREATMENT OF ASTHMA AND HAYFEVER BY HYPNOSIS

SIR,—The *argumentum ad hominem* has played a declining role in scientific controversy since its heyday during the Renaissance, when forensic skill could still make up for deficiencies in other respects Science is now a discipline in which impartial inquiry may be assumed as a matter of course, and it is agreed by all concerned that if observations are accurately made and experiments are well designed as well as being capable of repetition by other workers, then their scientific validity is quite independent of the temperament, motives, religious beliefs, taste, or any personal quality of the investigator, except perhaps his sagacity His work can only be criticised on these terms, and no scientific investigator worthy of the name places any reliance on persuading his opponent with rhetoric or on driving him from the field with invective, as President Conant so aptly puts it It is possible, therefore, if not certain that the failure to understand Dr Mason and Dr Black's contribution on my part, and I was not alone in this, may be elsewhere than in my alleged emotional attitude towards hypnotism

I am sorry to see, Sir, that you number yourself among the " statistics can prove anything " school, and I am sure that this view is partly based on a misconception of the use and function of statistical methods in biological research Such a misconception is well illustrated by a remark of Dr Mason and Dr Black in their letter of May 24 where they state " it often seems that almost any *result* (my italics) can be obtained (or refuted) by statistics" The fact is, as everyone should know, that statistical methods are used to determine the significance of experimental findings or observations and to test the validity of the hypothesis on which they are based In short, they are applied to results and not to obtain a result

Statistical methods are essential in a large proportion of biological investigations, such as therapeutic trials or studies of the effects of suggestion, because of the variability of living organisms and the sheer physical impossibility of studying the whole population If we are going to learn how suggestion works, we must have controlled studies of a random sample of the population One case just will not do The chequered history of hypnotism reveals the need for such studies and until they are carried out the wise practitioner will preserve that scepticism which is one of his marks of scientific sagacity

Dr Mason and Dr Black are not quite correct in their references to von Pirquet's "original allergy" He did not coin the term "allergy" with specific reference to old tuberculin in sensitised subjects, as they state in their letter Von Pirquet first introduced the term "allergy" in a special paper entitled Allergie,[1] the purpose of which was to devise a name for a phenomenon which far from being specific to old tuberculin was of widespread biological significance, as the following extract clearly shows

> Der Geimpfte verhält sich gegenüber der Lymphe, der Luetische gegenüber dem Syphilis-virus, der Tuberkulöse gegenuber dem Tuberkulen, der mit Serum Injizierte gegenuber dem Serum anders als ein Individuum, welches mit dem betreffenden Agens noch nicht in Beruhrung gekommen ist er ist deswegen noch weit entfernt, unempfindlich zu sein Alles was wir von ihren sagen konnen, ist, dass seine Reaktionsfähigkeit gändert ist
>
> Fur diesen *allgemeinen* (my italics) Begriff der veränderten Reaktionsfahigkeit schlage ich den Ausdruck Allergie vor

He goes on to say that he inserted this name to avoid confusion and standardise the nomenclature

London, S W 1 E J Moynahan

Sir,—The article by Dr Mason and Dr Black (April 26) demonstrates rather clearly the role of the central nervous system in controlling allergic reactions in man An experiment which should more precisely characterise the mechanism of this psychic "control" would be the effect of hypnotic suggestion on the skin reaction to histamine Would it be possible to abolish the cutaneous response to injected histamine by direct hypnotic suggestion in their patient?

Laboratory of Cellular Physiology and
Metabolism, National Heart Institute,
Bethesda, Maryland
Arnold M Katz

HYPOTHERMIA BY INTERNAL COOLING IN MAN

Sir,—Dr Khalil (May 24) describes a method of producing hypothermia in man by pumping cold water through an intragastric balloon Dr Khalil used this method in two cases in which intracranial tumours were removed surgically under hypothermia One of the two patients developed auricular fibrillation which lasted for a few hours

It seems likely that intragastric cooling might cool and irritate the neighbouring myocardium and that intragastric cooling might be more likely to cause cardiac arrhythmia than, for instance, surface cooling About one year ago I saw a patient who twice developed transient auricular fibrillation while drinking large quantities of ice water

The patient was a 31-year-old physician who had previously been enjoying good health On a warm day he had been doing moderately strenuous exercising, practising soccer A few minutes after he had finished he drank a pint and a half of ice water in the course of less than ten seconds Right away he noticed palpitations and diagnosed auricular fibrillation, which lasted for ten hours and then suddenly left him Six weeks later exactly the same thing happened, the patient again developing auricular fibrillation while drinking large quantities of ice water This time the auricular fibrillation lasted for eighteen hours, an E C G proved the diagnosis, and the patient took 0 4 g of quinidine before normal sinus rhythm was restored He has now stopped his unhealthy habit of drinking large quantities of ice water in a short time, and has had no further attacks of auricular fibrillation

"THESE DYING DISEASES"

Sir,—When I noticed among my patients with gonorrhœa one with a cervicitis and another with a urethritis after penicillin treatment, a cervical smear was made and gonococci still showed in one of them

Since I could not explain this I consulted Sir Alexander Fleming after he asked me to see him, just three weeks before his untimely death He did not believe that gonococci could be resistant to penicillin and asked me to show him a culture, which I promised to do when I took a smear in both these patients after menstruation Unfortunately he died before I could deliver the cultures, but when I asked him earlier whether it would not be right to vaccinate women with live gonococci intracutaneously, when the gonococci had become resistant, his answer was, "Before one does that" (and he knew about the striking results after 10,000 of these injections in chronic female gonorrhœa) "I would like to make sure that there really are penicillin-resistant gonococci"

I believe that active immunisation with live gonococci is the treatment of choice in penicillin-resistant gonococci, and I would say more Lately, Dr Sequeira of the Royal Free Hospital has given me many gonorrhœa cultures for intracutaneous injection in these cases, as well as in rheumatoid arthritis, and the results have been very gratifying

London, W 1 A A Loeser

VEIN STRIPPERS

Sir,—I was interested to read of Mr O'Malley's "adventure" (May 31, p 1180) and also Mr Ker's account of a modified Myer's vein-stripper (May 10, p 998) I, too, have passed the small end of a vein-stripper into the femoral vein on occasions, but luckily I have never found it irretrievable Two points in technique are worth mentioning here

One is the practice of some schools to strip the vein out from above down It is rare, however, for the small end of any stripper to be passed down with ease For this method an articulated guide-wire has to be passed up first, so the potential danger still exists The guide and stripper employed is the Swanson type which has been used (optionally) in Glasgow for many years

In this way it is claimed there is less immediate anchoring effect from the tributaries alongside, and consequently less chance of the main vein tearing The steel edge of the "cup" neatly divides the branches about one inch away Mr Ker's rubber-tubing modification shows he appreciates the same principle but is unaware of the existence of the superior all-steel instrument

The other point is the type of incision used to expose the termination of the long saphenous vein I favour a vertical approach because of the greater access it affords to the tributaries Very adequate exposure is obtained using a self-retaining mastoid retractor which leaves the assistant with both hands free

The oblique skin-crease incision is in my opinion the commonest cause of failure to ligate all the tributaries This is obvious when re-operating on "recurrent" cases The vertical incision, of course, cuts across the natural skin crease, and just crosses the inguinal fold Careful closure is required with sutures not more than 1 cm apart These must also be left in for a full ten days Normally I do not use any deep sutures

---

[1] *Munch med Wschr* 1906, 53, 145

Mr O'Malley does not say what approach he employed, or whether a separate incision was required With the vertical incision it can be simply extended up or down to cope with most stripper difficulties in the vicinity of the saphenous termination

Stobhill General Hospital
Glasgow

F T CROSSLING

THIRST

SIR,—Apropos of Dr Eaton's astonishment that salt depletion can give rise to a sensation of thirst (May 10, p 1021), it must be admitted that water is almost always lost as well Nevertheless, since in severe depletion the loss of salt is greater than the loss of water, the concentration of sodium in the serum is lowered and hypotonicity results

This has been commented upon by Dr O'Shaughnessy, late of Newcastle upon Tyne, in a letter in your columns[1] He noted that in the worst cases of cholera the blood loses not only a "large proportion of its water" but a "great proportion of its neutral saline ingredients" He further states that all the salts deficient in the blood "are present in large quantities in the peculiar white dejected matters" Since Dr Schmidt of Dorpat[2] has more recently confirmed these observations (he found the sodium reduced from the normal level of 3 18 g per kg of serum to 2 69 g in cases of cholera—a decrease from 139 to 117 mEq per litre), I have no reason to doubt their accuracy

That thirst occurs in cholera despite this lowering of serum-sodium is attested by Dr Latta, late of Leith,[3] who treated his patients by infusing salt solution intravenously, noting that " the poor patient, who but a few minutes before was oppressed with sickness, vomiting, and *burning thirst*, is suddenly relieved from every distressing symptom" (italics mine)

REGIONAL DISTRIBUTION OF CONSULTANTS AND S.H.M O s

SIR,—Thank you for publishing (May 31, p 1169) the S H.M.O figures for the various regions in response to my letter in your issue of May 17 Using these figures with the previously published population figures for each region I calculated the following

Region	*Population per S H.M O (whole-time equivalents)*
Newcastle	32,000
Leeds	31,000
Sheffield	35,000
N W Metropolitan	21,000
N E ,,	28,000
S E ,,	27,000
S W ,	22,000
South Western	25,000
Welsh	24 000
Birmingham	41,000
Manchester	36,000
Liverpool	30,000

With only two exceptions the backward areas in consultant cover are also the worst off for S H M.O s—in order of backwardness, Manchester, Sheffield, Leeds, and Liverpool—which is what I suspected In other words, the lack of consultants is not even compensated by an increase in S H M O s (of the two exceptions, Newcastle has the next best consultant cover, while Birmingham is about average)

The only conclusion is that the population in the backward regions is having a poor deal in the way of Health Service facilities, whereas since they are all highly industrialised and congested parts of the country they really require better than average

As regards consultants and S H M O s in these areas, they are obviously working under conditions where they cannot give the full benefit of their knowledge and skill because the numbers they have to cope with are too large I say "obviously", because having worked in one of the best organised regions I am now working in one of the worst (according to the above figures) and therefore realise the disparity in facilities from consultants right down the line, including ancillary medical and clerical staff, almoners, health visitors, &c.

General practitioners tell me they have to wait weeks for outpatient appointments and sometimes weeks for diagnosis reports—indeed, I am surprised they get reports at all sometimes, because I find it very difficult to get a reply when I refer patients to another specialist for an opinion I feel that the basic trouble is not that of a studied discourtesy but that too few people are trying with too few facilities to do too much work for too many

As I understand that regional-board finance is on a per-capita basis, may I put in a plea for the backward areas to have a higher proportional allocation of money than the advanced regions until the medical services throughout the country are more evenly distributed?

S H.M O (EX-SENIOR-REGISTRAR)

THE NATURAL HISTORY OF CHRONIC BRONCHITIS

SIR,—We are grateful for Dr Medvei's comments last week on our paper of May 31, although, since neither of us has seen the unpublished report to which he refers, we are unable to follow his argument completely

We were aware (one of us, A.S F, from several years in the Treasury Medical Service) of some of the medical and administrative problems involved in the disposal of postmen crippled by respiratory disease and of the special circumstances in some bigger offices But we could find no evidence that any such localised anomalies in disposal materially affected the broad pattern of results in the large groupings of areas, ranked simply on the local frequency of fog, used in our study The only observations restricted wholly to the London area dealt with the timing of onset of absence because of bronchitis in relation to climate.

All occupational groups are selected but this does not mean that their experience is of no general relevance The wastage-rate because of bronchitis among postmen in different areas is quite closely related to local death-rates from that cause among all middle-aged males Nor does such selection make "controls" superfluous Without control comparisons some of the results would have been meaningless, and we believe that presumably healthy postmen are the most appropriate choice in these circumstances

It appears, however, that Dr Medvei would have us defy the usual scientific conventions by going beyond the data presented in our paper It is clear from the distribution of bronchitis frequency in adult sickness-absence records that all future invalids do not present with repeated attacks before the age of 45 Our sober assessment that these records had "some" value recognises that, taken alone, they are certainly not infallible Dr Medvei's term "exceptional" presumably derives from his experience of their use with additional clinical data—e g, on childhood disease, obtained by detailed interview

Our hesitancy about drawing conclusions on the role of smoking in chronic bronchitis resulted from the rather indirect nature of our evidence We have already referred elsewhere[1 2] to Oswald and Medvei's paper which showed that the prevalence of histories suggestive of chronic bronchitis is similar in the two sexes but only when job, place of work, and smoking habits are alike We ourselves could offer no fresh information on this important point and a further reference would have been irrelevant

A DRESSING FOR BURNS

SIR,—During the four years I spent in New Zealand I used a material known as 'Telfa' dressing on many patients with extensive burns This material is virtually non-adherent, and can in consequence be removed painlessly without an anæsthetic

As far as I can gather telfa dressing is not available in this country, and I find that most of my colleagues have never heard of it Is it too much to hope that some British manufacturer will produce a similar product?

'Telfa' dressing is made by Messrs Bauer and Black

Edinburgh, 8

MICHAEL WOODRUFF

CARDIO-CHARTING

SIR,—May I comment on the review of my book, *Cardio-charting*, in your issue of March 8, 1958?

It is true that many methods of clinical recording of heart auscultation have been suggested and that some are even used individually—but none are all-inclusive, nor universal in scope Each clinician uses his own personal method of charting his findings Consequently his records are either too long or too short, often they are incomplete or illegible, and occasionally these charts can be understood *only* by the author himself Whatever the merit of such charts, they are only personal and have not the quality of a standard system

It is true that constant progress is made in the knowledge of hæmodynamics—but this has nothing to do with a *method of charting* the clinically perceived acoustic cardiac phenomena, whatever their physiology

Moreover, as clearly indicated in my book, the limited clinical examples as well as the limited number of coloured illustrations were given (1) as a reminder for students of basic murmurs, well known and described in textbooks, (2) as samples of the way the method should be used when recording these and any other murmurs

Cardio-charting is not a textbook of physiology, nor a compilation of opinions

I welcome any criticism, provided it bears on the substance of the subject, but I was surprised, indeed, to find in *The Lancet* a review which had no relationship to the description of my method

Cardio-charting, as the title clearly indicates, is a method for registering uniformly all cardiac auscultatory findings in a practical and a useful way blue symbols for heart sounds, red symbols for heart murmurs The resulting permanent record is helpful not only for the examining physician himself to recollect his own past findings, but it is also helpful in promoting a mutual and universal understanding of chartings made by any physician in any part of the world, irrespective of language

New York

ARTHUR BRISKIER

*** Dr Briskier's book has served a useful purpose in drawing attention to the need for more accurate description of heart sounds and murmurs *In our view, however,* his system has few practical advantages over the drawing of sounds and murmurs in the way that many cardiologists already do, and his use of musical connotations and colour adds complications —ED L

DEATH OF A BOXER

SIR,—Before condemning what some of us believe to be the wholesome exercise of amateur boxing our profession must be sure of its facts

For example—if I may make a personal reference—I have been associated with schoolboy and R A F boxing for well over twenty years in the capacity of medical officer, examining candidates and observing them during contests The lads we deal with are nearly always good sporting types and largely through the art of boxing develop such qualities as courage, ability to keep good-tempered in the face of rebuffs from determined opponents, alertness, and efficient eye-muscle coordination I have not come across one case showing evidence of brain injury among these young amateurs, and it seems unlikely that either in school or Service such cases would escape notice for long Perhaps I have been specially fortunate, colleagues with similar or greater experience could perhaps enlighten us on this point

By all means let us have full investigations, accidents may accompany any form of physical activity and many people may get bangs on the head, but I venture to suggest that it is not advisable to generalise about the effects of such injuries pending impartial investigation I am inclined to doubt whether the effects of the ordinary "knock-out"—uncommon, by the way, in my experience in schoolboy boxing—are comparable to the results which Dr Byrom tells us accrue if the dura of an anæsthetised animal is opened and the surface of the brain touched

P R KEMP
Assistant Principal School Medical Officer,
City of Birmingham

Birmingham

SIR,—It is probable that the answer to Dr Byrom's question in the final paragraph of his letter last week is in the negative and that it would be about as futile to marshal the facts about boxing and to keep them before the public as it has been on the subject of cigarette-smoking, bronchitis, and bronchial carcinoma One of the reasons is that most of the medical profession seem to be indifferent to these evils and have given neither a lead nor an example to the laity the majority of doctors smoke cigarettes, and many attend boxing matches Only lonely and individual voices, like those of Dr Summerskill, Mr Doggart, and Dr Byrom, are heard crying in the wilderness of crass indifference

We live in an age as brutal, violent, vicious, and immoral as any of those in recorded history that preceded the Christian era, and with less excuse Boxing promoters, boxing journalists, and patrons of the prize-ring, lacking the courage of those who provide the "entertainment" but gloating nevertheless on knockouts, cut eyes, and pouring blood, are the ferocious and brutalised descendants of those who, in gladiatorial times, without mercy turned down their thumbs to make a Roman holiday It is as monstrous, wrong, and indefensible to cause gratuitous injury to the miraculous organs of the body as it would be to detonate an H-bomb without provocation, and it is as necessary for the Government of the country to enact legislation forbidding it as it was for the same authority to legislate against crime

When a sports writer on a well-known national daily newspaper can write that he feared a certain boxer had "lost his *killer* (my italics) instincts" and when feral cries of "kill 'im, kill 'im" can be heard at almost any prize-fight on radio or television, it is long past time for those who respect what they cannot create or repair, for the imaginative and for the fastidious, and for those who are alarmed at the continued debasement of human life and values to cry out upon a disgusting outrage against human dignity and decency that has killed some and reduced many to a state bordering upon idiocy

Folkestone, Kent

B G EDELSTON

ANTIBODY-ANTIGEN REACTIONS OBSERVED BY FLUORESCENCE

SIR,—Your annotation of May 31 gives the impression that the Coons technique has scarcely been tried in this country. This is far from the truth: the localisation of tissue antigens in the kidney[1] and the relation between autoantibodies and Hashimoto's disease[2] are but two of the recent studies using the method. Your hope that "simpler techniques will no doubt be introduced" ignores the important contribution recently published in your own columns.[3] This is carrying modesty a bit far.

Department of Bacteriology,
University of Aberdeen.
A. MACDONALD

SIR,—Your annotation reviews a very limited amount of the information which has been obtained by this technique. Studies of viruses, plasma-proteins, and tissue antigens and of antibody production have each produced more papers during the present decade than the study of bacteria or their products. Even in the field you select for detailed review, several contributions have been overlooked.[4-8] It is regrettable, too, that reference to British work is so scanty. The technique has been used in at least nine laboratories and papers from at least six of these have appeared during the last year[9-16]; Weiler's work, also, was done and published in this country.[17] The modification described by Chadwick et al.[14] has simplified the technique, introduced a reliable alternative fluorochrome, and reduced the incidence of non-specific staining. Kaplan[18] has recently described a further modification which eliminates non-specific staining with fluorescein-labelled sera.

BRUCE CRUICKSHANK

THE RUSSIAN VACCINE

SIR,—The letter of Dr. Liversedge last week was a very fair summary of the position that arises from the publicity given to the Russian vaccine for multiple sclerosis. During the recent visit of the Socialist Medical Association delegation to the Soviet Union, we endeavoured to get some information about this vaccine. Unfortunately we were not able to get in touch with Professor Shubladze, but we had a long conversation with Dr. Zhdanov, a deputy Minister of Health and himself a virologist. We did not gather from him that the vaccine is being widely used in the Soviet Union, and indeed we have been much surprised to find how much of it appears to have been made available for export. He told us that they were very well aware of what had been said about the vaccine in other countries and implied that it had been put back on an experimental basis and was now the subject of further extensive laboratory investigation. This is something, he concluded, which clearly needs testing, and when the results are available they will be published in the scientific press at once.

In these circumstances we have been answering the many queries we have had in a very cautious way and have advised doctors and patients not to be optimistic about it and not to spend large amounts of money on it until more information is available. We agree, however, with Dr. Liversedge that the attitude taken by the Ministry of Health on this is far too negative a one and if the material is to be imported it should be the subject of real scientific test and report.

ZIRCONIUM GRANULOMAS

SIR,—Your annotation (May 31), in reviewing the admirable work of Shelley and Hurley on zirconium granulomas, supported their claim to be the first to demonstrate a granulomatous reaction in the skin by experimental means. In so doing you overlooked the work on beryllium that has been carried out in this country. In 1955 I reported the production of a sarcoid-like granuloma after a positive epidermal reaction to a very dilute solution of beryllium sulphate in a case of beryllium disease.[1] This observation has been confirmed in a second case of my own reported recently,[2] and by Jordan and Darke.[3]

In all these cases the epithelioid reaction has followed the application of very dilute solutions to the skin so that no question of a foreign-body reaction can be entertained. It would appear to be a type of delayed allergic response to minute amounts of beryllium, very comparable with the reaction to zirconium.

Sheffield.

STOKES-ADAMS ATTACKS TREATED WITH CORTICOTROPHIN

SIR,—The paper by Dr. Litchfield and his colleagues in your issue of May 3 prompts us to record the following case.

A man aged 68 was admitted to this hospital on April 26 with a history of syncopal attacks for six months. Immediately before admission they were occurring, on average, four or five times daily. An attack was observed shortly after admission. There was the classical pallor, followed by flushing on recovery, of Stokes-Adams syncope. Although, on that occasion, actual cardiac standstill was not confirmed by his pulse or by auscultation, this has been observed in subsequent episodes. The only significant findings were moderate cardiomegaly, free aortic reflux, and a blood-pressure of 200/65 mm. Hg. The electrocardiogram showed a P-R interval of 0·24 seconds and a right bundle-branch block. There was no aortic calcification and the Wassermann reaction was negative.

On the first few hospital days he averaged four to five attacks daily with, however, a number of minor episodes of transient faintness without loss of consciousness. Ephedrine (gr. ½ q.d.s.) and 'Hyperduric' adrenaline (2 ml.) 12-hourly had no effect on the frequency of attacks, so, stimulated by the experiences of Dr. Litchfield and his colleagues, we stopped other drugs on May 6 and substituted prednisilone 20 mg. q.d.s. On May 7 he had forty attacks, the next day three, and he has now remained free for twelve days. His last cardiogram shows a normal P-R interval (0·2 sec.). The right bundle-branch block is unchanged. We are now gradually reducing the steroid.

It is, as Litchfield et al. point out, a matter of common experience that Stokes-Adams attacks vary in frequency

M J TEMPLER
WAVERLEY

THE TOURNIQUET

SIR,—Your leader of May 31 put the case for and against the tourniquet with clarity and balanced judgment, but I think does not answer effectively two points I made in my letter of March 15 infection is likely to establish itself more easily, and damaging effects can follow the sometimes very great œdema

Your erudite leader says there is no clear evidence on the increased liability to infection But the case for this is self-evident Whilst the tourniquet is on, the life processes of the cells, the reaction to infection, the responses to trauma are in abeyance It is on to these defenceless cells that staphylococci fall, a perfect culture medium And we must remember that they divide every half hour But when the constrictor is removed conditions still remain favourable, for the inability of the lymphatics to absorb the œdema, which may be very great and last for days, denotes severe damage to the mechanism of absorption, the permeability of the endothelium of the lymphatics and the ability of the muscles to assist mechanically Thus not only is there stagnant plasma in the tissue-spaces but also no fresh plasma containing immune bodies can exude into them The conditions are ideal for infection There is no need of experiments to prove this contention, for the facts stand out and only observation and a little thought are needed to recognise the situation

Paralysis of the hand and infection in a limb are serious risks and I doubt if these limbs are ever restored completely to normal It is small consolation to a patient suffering paralysis or a long drawn-out infection to be told that his predicament is rare and only exceptionally permanent when he knows that it could have been avoided altogether had the surgeon adopted another method of operating

Basingstoke

CHARLES A PANNETT

DISPLAYING AXILLARY LYMPHATICS

SIR,—Mr Heanley asks (May 31, p 1181) whether anyone has published data on axillary lymphatics using patent-blue dye to visualise them He will find references to it in a Hunterian lecture [1] and in other papers on the lymphatic system by Mr G W Taylor and myself describing work done at St Bartholomew's and St Thomas's Hospitals during the past decade

We found, like Mr Heanley, that the lymphatic pathways from the arm could be readily identified in the axilla during the operation of radical mastectomy It appeared to us that preservation of the lymphatic pathways from the arm was incompatible with the clearance of the axilla which is part of Halsted's radical mastectomy, because they were so intermingled with the pathways draining the breast Mr R S Murley also studied some of his patients in the same way and came to the same conclusion We have not pursued the problem further, because we abandoned the radical operation for other reasons some years ago It may well be that Mr Heanley may find by careful dissection that the two pathways can be separated and it will be interesting to hear of his results in the future

TREATMENT OF OBESITY

SIR,—Dr Jacoby (*May 31*) suggests that weight reduction by conventional methods, or by the hydrophilic-colloid method, is not enduring In the case of the colloid method my experience is that after six to eight weeks' treatment the patient has become "reconditioned" to eating sensibly and continues on the right path for a variable period thereafter This may vary from weeks or months to an indefinite period, and in any case if the patient's dietetic habits relapse this can be easily remedied by another course of treatment, which is inexpensive, non-toxic, and needs the minimum of the doctor's time

In the criteria I suggested for weight-reducing treatments (April 26) I omitted to include "economy of doctor's time" This is most desirable, but I note Dr Jacoby recommends psychotherapy as an alternative—and though I agree that psychological factors exist in some cases, the obese are many and the psychiatrists few For this reason psychotherapy seems impractical for the masses, quite apart from the fact that the professional-time factor would make the cost very high

I am grateful to another physician who, in a personal communication, pointed out that, ætiologically, it is not so much overeating as incorrect selection of food which is important Of course he is right, "incorrect eating" is a much more apt term than "overeating" In giving instructions to patients who are about to reduce I *do not* give a *definite* diet, because of the efficacy of the method, this is unnecessary, but the patient receives a written explanation of the principles of correct food selection My correspondent relied on re-educating his patients to better dietary habits, but I feel that without some effective aid to bring about the "reconditioning" it must be hard going for the doctor and hard on the patient

Harperbury Hospital,
near St Albans

JOHN N BADHAM

SIR,—Dr Jacoby (May 31) appears to have misunderstood my letter of April 5, for he accuses me of extolling the very type of treatment that my letter criticised

"It is easy", he states, "to put a patient on a diet, give appetite-reducing pills, and get considerable reduction in weight" This seems doubtful A recent examination of the records of 150 patients (average overweight 56 lb) treated for obesity along these lines showed that only 8 of them reached normal weight

"This weight is regained almost invariably once supervision is discontinued" This is borne out by work done both here and elsewhere 114 patients treated for severe obesity with satisfactory weight loss one to eight years previously were recalled to hospital Their average weight was only 1 lb less than before treatment began Only 3 had reached normal weight

Because of the poor results of previous treatment, an obesity clinic was started in this hospital The therapeutic regimen is very different from that which Dr Jacoby implies we are using He states that my letter "completely ignores the psychosomatic aspects of obesity" Yet the letter said, "time has been spent in discovering the background of each patient's obesity and the special difficulties in treating it"

The patients attend the clinic frequently (usually at intervals of two or four weeks for the first months) and see the *same* doctor at each visit All but a small proportion have had previous medical treatment which failed Yet most of them find that the personal interest taken in them and the opportunity to discuss their problems enables them to reach normal weight, often without the use of drugs 105 patients have attended regularly until discharge over the past two years 102 of them reached normal weight These have all been followed up, and none has so far relapsed

The psychological background of obesity, described by Dr Jacoby, has been known for many years In some patients it is obvious In many it is undetectable, either by patient or doctor, the fact that these patients reach and maintain normal weight without difficulty suggests that even if "unsatisfied oral needs" are the cause of the obesity, they can for practical purposes, be regarded as "within normal limits".

Stressed less often than the psychological causes of obesity are the psychological results of the condition. The improvement in outlook and mental state of many patients after losing several stones in weight is enormous. They are able to cope with their lives and their problems much more effectively than before. The improvement in health and appearance helps them to do this, and adds to their determination "never to let it happen again".

But before this stage is reached, a patient may pass through a period of difficulty, with multiple psychosomatic symptoms. Many state that these symptoms were the cause of failure of previous treatments. It is during this period that attendance at the clinic is particularly valuable. Often discussion and reassurance is all that is required, and treatment continues smoothly.

"Obese patients require psychotherapy," writes Dr Jacoby. Experience in this clinic suggests that the majority require no more than is achieved by repeated conversations with a doctor who is interested in them. But that much they do need.

I thank Dr Alexander Kahan, consultant physician at St. James' Hospital, Balham, for permission to do this work and for his frequent advice, helpful criticism, and constant encouragement. I thank him also for permission to publish this letter.

Obesity Clinic,
St. James' Hospital,
Balham, S.W.12.

A. G. MULLINS

INFLUENCE OF THE TEMPERATURE OF INGESTED SUGAR SOLUTIONS ON THE BLOOD-SUGAR LEVEL

SIR,—Bicknell[1] described a rarely mentioned and interesting difference between the action of cold and warm foods. After eating cold foods hypoglycæmia develops sooner than after the ingestion of warm foods. In those diabetic patients who got their insulin before a supper consisting of cold meat, hypoglycæmia developed sooner than in patients whose supper consisted of warm meat of the same quality and quantity.

The inner temperature of the stomach can be changed significantly by the temperature of the ingested food.[2] The activity of intestinal absorption increases in proportion to the temperature of the ingested food between 20° and 40° C.[3] Some findings suggest that cold foods leave the stomach more rapidly and peristalsis increases—that is, absorption is less efficient. On the other hand, some observations on the stomach emptying time for cold foods compared with foods of normal temperature indicate that cold food may in fact leave the stomach more slowly.[4]

The published data are thus conflicting and the further examination of the problem might be important, for changes in blood-sugar level, and the eventual change in the blood level of other nutriments, can have a decisive influence on the function of the endocrine system and so upon the whole organism.

We therefore decided to examine the difference between the effect of warm and cold foods upon the blood-sugar level in animal experiments.

12 male albino rats, fasting for twenty-four hours, received 3 g. of glucose in 6 ml. of water into the stomach through a gastric tube. The animals were paired, one receiving the solution at a temperature of 2–6° C, the other at 38–42° C. Blood samples were taken from the rats' tails before passing the gastric tube, and then every thirty minutes for two hours. At the end of the experiment the rats were sacrificed by decapitation. The intestinal tract was washed out with isotonic NaCl solution, and the sugar content of the washing fluid was determined by the Hagedorn-Jensen method.

After the ingestion of cold glucose solution the blood-sugar curve was low and drawn out, after a warm solution the curve rose steeply. The glucose content of the intestinal fluid was significantly higher in those animals who got the cold solution—that is, absorption was faster in the warm group.

The blood-sugar rise was about 68% greater after the administration of warm glucose solution than after ingestion of cold glucose solution.

This phenomenon is of importance in the dietetic treatment of diabetic patients. The consumption of a cold cream rich in sugar and protein causes a uniform and slow rise of the blood-sugar level, and this effect might be enhanced by the action of proteins in decreasing the blood-sugar.[5]

The published data and our own findings suggest that this matter needs further consideration.

TOXÆMIA IN PREGNANCY

SIR,—I read with interest and with some astonishment your account (June 7, p. 1235) of a new film on this subject which was introduced at its first showing by Professor R. J. Kellar. You describe it in the following words:

> "Skilfully photographed in colour, it points good-humouredly to the dos and don'ts relevant to toxæmia. Mrs Stout, caught during a light snack at the fish-and-chip shop, Mrs Pale, a heavy smoker and inadequate eater, and Mrs Weary, struggling for prodigious hours a day on behalf of her large family, illustrate the don'ts. The advice about diet includes the instruction to use salt in cooking but not otherwise. The tone of the film seems exactly right for its purpose, and several obstetricians who saw it last week said how much they admired it."

I am interested in toxæmia of pregnancy and would like to have references to the evidence that it is commoner in stout women. If this is true, it would seem likely that Mrs Pale, although saving up for carcinoma of the bronchus in later life, was probably protecting herself from toxæmia, or is there also evidence that it is particularly common in thin women? If so I would again like the reference. Perhaps Mrs Pale's diet was only inadequate in iron and vitamins, but I know no evidence that such inadequacy predisposes to toxæmia, and my recent survey of the incidence of toxæmia in the wives of young doctors would not lead one to suppose that it was a factor.

Finally, Mrs Weary is obviously meant to depict the unfortunate woman whose child-income ratio is too high. Does the film make it clear that she has already had toxæmia with her other pregnancies? If not she is surely the most unlikely person to develop it, for one of the few facts fully established about this mysterious condition is that it is much more common in first pregnancies and very rarely occurs for the first time in a third or fourth or subsequent pregnancy. If there is substance in my criticisms would it not have been better if the obstetricians who saw it had condemned rather than admired a film which departed so far from scientific truth?

ÆTIOLOGY OF PRE-ECLAMPTIC TOXÆMIA

SIR,—Professor Gray and Dr Rinsler in their letter of April 12 claim to have demolished the foundations of the long and widely held belief that the adrenal cortex plays a major role in the ætiology of pre-eclamptic toxæmia and eclampsia With respect I submit that their claim cannot be substantiated Nowhere in my paper of Jan 18 did I suggest that the glucocorticoids were responsible for the pre-eclamptic syndrome On the contrary, I expressly stated that the mineralocorticoids were "probably the hormones chiefly involved in pregnancy toxæmia" I also gave reasons for believing that aldosterone was not the responsible mineralocorticoid I now suggest that it may be deoxycortone acetate or a compound with similar action

It would, indeed, be rash to base an opinion regarding the secretory activity of the adrenal cortex on histological appearances alone, for they are notoriously difficult to interpret There is, however, another possible source of active hormones—namely, the placenta—which is known to contain substances that possess adrenocortical-like activity, though the yield of bioactivity is much less than that from adrenal tissue It is not yet known whether the active factors have been produced in the placenta or simply stored there after having been transported from some extraplacental source, [1] though there are certain facts that favour the adrenal as the main site of their production As to potassium excretion, which is usually increased in adrenal cortical hyperactivity, it is well known that there are circumstances in which it is not, and until more is known about it, it would be wise to refrain from basing important conclusions upon it

I thank all the correspondents who have contributed to the discussion on my paper I do not wish to support any particular theory or point or view on this difficult problem merely because it is my own, but only to arrive at the truth

Sydney F J BROWNE

SURGERY OF PARKINSONISM

SIR,—I have read Mr Oliver's communication (May 24, p 1121) describing the surgical techniques used in the treatment of Parkinson's syndrome and would offer the following comments

Whereas the postmortem lesions present in non-infective parkinsonism are well understood, the precise ætiology remains entirely unknown Surgical procedures are purely empirical and are not based on any sound physiological theory Furthermore, if some improvement in the rigidity is achieved by the various operations described, relapse is certain as the lesions in the midbrain progress

I have recently discussed with eminent American authorities the minimum indications which must be present before surgery or irradiation by multibeam ultrasonic waves is considered, and we agreed they are

(1) Unilateral rigidity and tremor, preferably in one limb only

(2) Absence of other serious disease (this means that the patients must be a good operative risk below the age of 50)

(3) Failure of drug therapy

I have recently studied in great detail the case-histories of 398 patients attending my Parkinson's clinic regularly, and only 15 were found to have these characteristics and all have responded satisfactorily to B-dimethylaminoethyl-2-methylbenzhydryl hydrochloride ('Disipal'), ethopropazine hydrochloride ('Lysivane'), 10-(1-methyl-3-piperidylmethyl)-phenothiazine (pecazine) ('Pacatal'), or benzhexol hydrochloride ('Artane'), or a combination of these drugs 3 patients suffering from unilateral tremor and rigidity were subject to pallidectomy before attending my clinic, and after the operation the disease rapidly spread to both sides It is concluded that surgery offers little hope of relief for those suffering from parkinsonism

Dudley Road Hospital,
Birmingham R O GILLHESPY

VISITING MENTAL HOSPITALS

SIR,—I have read Mr Woodley's letters of May 17 and June 7 with amazement, for I believe that medical superintendents in general welcome visitors to their mental hospitals

Here we are fortunate in that we have a very active League of Friends, who make a special feature of visiting lonely patients, and as all the wards are open they come in and go out at any convenient time as they please If Mr Woodley and his party care to visit us I shall be pleased to give them the same facilities

The Central Hospital,
nr Warwick E S STERN

RETINAL PHOTOGRAPHY

Mr A H DEGENHARDT, F B O A, a director of Degenhardt and Co Ltd, Carl Zeiss agents, writes

"Your editorial on retinal photography in the issue of May 10 says 'In this respect modern retinal cameras are less satisfactory than the original Zeiss-Nordenson camera, for with them the photograph records a smaller area of fundus and consequently ' This may be true of some modern retinal cameras but it is a criticism which certainly may not be levelled against the new Zeiss instrument In this the field of view is considerably larger than in the old Nordenson and as the magnification is less it follows that the area of fundus recorded is appreciably larger than in the earlier instrument"

Public Health

Poliomyelitis Vaccination

WITH the arrival of a further 1,000,000 doses of Canadian Salk vaccine, the initial order of 4,000,000 doses placed with the Connaught Laboratories, Toronto, last September, has been completed This final consignment was not expected until later this month, but the laboratories hastened delivery to help the current British vaccination programme All the Canadian Salk vaccine has passed the M R C tests This latest consignment brings the total of vaccine, both British type and Salk, which has been distributed throughout Great Britain, to just over $13^1/_2$ million doses, of which $9^1/_2$ million have been distributed since last January

Registration returns from the local authorities show that by April 30 just over 6,250,000 children and other priority groups had registered, of whom just over 3,640,000 had received both injections, or were awaiting their second The present position is that with the latest Canadian batch enough vaccine will have been distributed to cover all those registered and awaiting vaccination on April 30, but some allowance must be made for unavoidable wastage A statement from the Ministry of Health says "as far as we can judge" there should now be enough vaccine to cover practically all of those in the priority groups who had registered by April 30 Registrations are, of course, continuing and vaccination will also go on during the summer months Further batches of vaccine, mostly Salk, will continue to be issued to keep pace with new registrations"

Food-poisoning in Birmingham

EIGHTEEN employees at the Birmingham works of a biscuit manufacturer were taken to hospital with food-poisoning on June 6 They fell ill a few hours after a lunch of sausage-and-onion pie at the works canteen Six patients were detained in hospital for observation, but it is reported [1] that none of them is seriously ill Further inquiries into the cause of the outbreak are proceeding

X-ray Machines in Shoe Shops

REQUIREMENTS for the control of shoe-fitting fluoroscopes have been formulated by the Home Office and have been accepted on behalf of the manufacturers and users by the Pedoscope Co , Ltd , the Footwear Distributors Federation, and the Retail Distributors Association They include

(1) The dose-rate in the beam of the machine about the position occupied by the sole of the foot when the machine is in use shall not exceed 8 r per minute, and the dose-rate on the outer surface of the machine shall be such that the dose received by the fitter shall not exceed 0·03 r per week.

(2) The machine shall be fitted with a three-selector device labelled for men women, and children, and the exposure conditions shall be such that the dose-rate when the control for women is operated shall not exceed 6 r per minute, and when the control for children is operated, 4 8 r per minute

(3) The machine shall be fitted with a time-limiting device so that the X-ray beam cannot be switched on for more than 5 seconds at a time and each exposure is followed by a dead time of not less than 30 seconds before the tube can be re-excited

(4) The manufacturers shall not, after July 1, 1958, supply any machine that does not conform with these requirements, and they shall, as soon as practicable and in any event before July 1, 1963, provide for the alteration of any existing machines which the users are willing to have altered so that they comply with the requirements

(5) In each shop using a shoe-fitting fluoroscope there shall be at least one member of the staff on duty who understands the appropriate control measures to be exercised

(6) The machine shall wherever practicable be situated close to and facing a wall with the foot-aperture directed away from the normal traffic of customers and staff

(7) A notice shall be mounted on each machine near the view-screen so that it can easily be read by customers in the following terms '*Notice* —Repeated exposure to X rays may be harmful It is unwise for customers to have more than twelve shoe-fitting exposures a year", and before carrying out an X-ray examination the fitter shall draw the client s attention to the notice displayed

(8) Users of a machine supplied before July 1, 1958, shall not use it after July 1, 1963, unless it conformed with requirements 1 to 3 above at the time of delivery or is subsequently altered to conform.

Obituary

JAMES THOMPSON DUNCAN

F.R.C S I , D T.M. & H.

Dr J T Duncan, who died on June 3, was the first reader in medical mycology in the University of London He held this post at the London School of Hygiene and Tropical Medicine, where he was director of the standard mycological laboratory of this country

Before he began to study medicine he was a chartered accountant for five years, and he qualified from the Royal College of Surgeons in Ireland in 1911 After holding house-appointments at the Adelaide Hospital in Dublin he joined the staff of the King Edward VII College of Medicine in Singapore, and he also held the part-time appointment of Government pathologist in the Straits Settlements In 1916 he was appointed lecturer in clinical medicine and pathology at the college, and for two years he was also acting principal. In 1919 he returned to this country, and the following year he became lecturer in pathology at the London School of Tropical Medicine When the London School of Hygiene was established in 1927 he was appointed lecturer in the department of bacteriology and Milner fellow

Duncan had early become interested in the fungus diseases, and when the Medical Research Council's committee on medical mycology, of which he was chairman, decided during the 1939–45 war to survey the fungus diseases of Great Britain he was put in charge of the investigation Requests for material brought about 1500 specimens, and Duncan was largely responsible for their examination and identification This work was at first carried out at Winchester, where he was in charge of the war-time emergency public health laboratory, and was continued at the London School of Hygiene and Tropical Medicine after his return to his academic duties At this time he was also collaborating with Dr S P Wiltshire and Dr Charles Willcocks in editing the *Annotated Bibliography of Medical Mycology*, which was published in 1947 In that year Duncan's contribution to medical mycology was officially recognised when the University of London created a readership for him

P M -B , who has been his friend for nearly forty years, writes

Duncan was a very popular person with his modest ways, soft-spoken Irish brogue, and cheerful friendly disposition. He possessed the true and devoted scientific spirit and worked away, often with a smile and a jest, at many branches of pathology and bacteriology Although he was a good critic he was quite free from any thoughts of jealousy, hatred, malice, or uncharitableness His own work was of fundamental and lasting value. He brought order out of chaos and regularised the nomenclature of the pathogenic fungi of man. Only those familiar with this subject can realise what he did to put mycology on the map For some years he had been writing a standard book on medical mycology to which he had given all his energies and thought. It was near completion when he died, and it is to be hoped that it will soon see the light of day

Duncan was fortunate in having, as his pupil and assistant, his daughter Mrs Jacqueline Walker, who is director and lecturer in her father's old department.

JOHN FRANCIS COATES

M D Brist , M.R.C.P

Dr John Coates, consulting pædiatrician to the South Somerset clinical area, died at Bridgwater on May 24 at the age of 50

His father is Dr Richard Coates, of Burnham-on-Sea After graduating M.B with honours from the University of

Bristol in 1930, John Coates held house-appointments at Bristol General Hospital In 1935 he took the M R C P and his M D with distinction Soon afterwards he returned to Bridgwater to take over the family practice on his father's retirement Later he became honorary medical officer to Bridgwater General Hospital

During the late war he served with the R A M C He spent most of his time in the Middle East, and, with the rank of lieut -colonel, was medical adviser to the Persia and Iraq Commands After he returned to civilian life he decided to specialise in pædiatrics, and held an appointment as senior resident medical officer at the Victoria Hospital for Children in Chelsea before returning to Somerset Soon afterwards he was appointed to the staffs of Musgrove Park Hospital and Yeovil Hospital

H P writes

I first met John Coates nearly thirty years ago when we were members of the " house " at the Bristol General Hospital Already he was acquiring the great learning that marked him out He was reading deeply in the underlying philosophy of medicine at an academic standard outside the range of other housemen He was determined to lay firm foundations of a wide mastery of medicine, and to this end spent several years as a resident in general medicine and surgery and in the special departments None the less, then as through all his life, he kept the " common touch ", and was a delightful and cheery companion His room was a meeting-place where shop chatter *mixed with music, both lowbrow and classical*

After the war he specialised as a pædiatrician, and his name rapidly became identified with this specialty from Yeovil to Minehead and from Glastonbury to Taunton His centre and pride were his pædiatric wards at the Taunton and Somerset Hospital, but he was called to all the hospitals around He paid for his success in having little time to call his own It was a ready saying at social parties that if the 'phone went it was sure to be for " Jackie " His colleagues entrusted him with the postgraduate studies of their area, and the weekend courses he organised were a pleasure to both attending practitioners and lecturers He will be missed for his wise medical counsel, his care of the illnesses of the children of his colleagues, and the friendship and hospitality he and his wife provided for their many friends

Notes and News

WORLD HEALTH ASSEMBLY

At the World Health Assembly, which opened in Minneapolis, Minnesota, on May 30 after a session commemorating the tenth anniversary of the World Health Organisation,[1] Dr Leroy E Burney, surgeon-general of the U S Public Health Service, was elected president Dr Burney declared that W H O 's role should be fourfold (1) to coordinate and help strengthen research through scientific meetings and the dissemination of literature, (2) to aid in training health personnel, (3) to help reduce the lag between the discovery and the application of new methods of diagnosis and treatment, and (4) to enlist the participation of groups outside the traditional health setting—such as occupational, welfare, social, and education workers Dr Burney presented the Leon Bernard Foundation prize to Dr Thomas Parran, now dean of the Graduate School of Public Health in the University of Pennsylvania

In the debate on the Director-General's annual report for 1957 Prof V M Zhdanov (Soviet Union) indicated his delegation's approval of the emphasis on the eradication of communicable diseases such as malaria He added that the Soviet Union, with its vast facilities for the control of communicable diseases, in the form of both institutions and specialised personnel, was ready to accept medical workers from abroad for training and to send its own staff to other countries to help further such campaigns He praised the work of W H O 's influenza centres in dealing with the pandemic of 1957 and the achievements of the W H O Expert Committee on Poliomyelitis The U S S R was ready, he said, to participate in this exchange of scientific information

A budget of $14,300,000 for 1959, proposed by Dr M G Candau, director-general of W H O, was approved unanimously by the two main committees In the past ten years W H O 's income has expanded steadily from $5 million A report by W H O 's external auditor revealed that 97 08% of contributions to the 1957 regular budget had been received from active member States—the highest percentage since the Organisation's inception The Executive Board submitted a proposal to encourage contributions to the World Malaria Fund from all possible sources Dr T W Tewari said that India's malaria-control campaign had now been transformed into an eradication campaign, with 230 anti-malaria teams in the field, India would pay the entire running costs The Assembly elected Tunisia to designate a person to serve for a year on the Executive Board, to complete the three-year term of the member designated by Syria, now that that country has merged with Egypt to form the United Arab Republic At a meeting of the programme and budget committee, several delegates deplored the fact that the high cost of vaccine prevented them from organising extensive poliomyelitis-immunisation programmes

AN INJUSTICE MITIGATED

The rules governing grants to boys and girls who win State scholarships have been grossly unfair to many parents, because of ans test In principle there ought to be no
means tes who pays his required contribution to
the comm form of taxes, should be entitled to
whatever t y offers in the way of educational bene-
fits, and it that the more a parent pays into the
common c he can hope for any help out of it
But, theory has le c patent injustice
in practice test unrealistic
deciding father of olar shall pay,
only for enses borne
relation the his contri-
has y his income
—so d surtax "
professional
too large an

income to qualify for a grant but too small an income to pay for a university education for their son or daughter Few parents, unless they have capital, can now afford to send more than one, or possibly two, children to the university in the absence of any kind of grant, and in families clever enough to have several State scholars the only way in which university education could be secured for all of them has been for the father to retire from work—or from life "I could not have gone to the university if my father had not died", some students have said

The Ministry of Education is now to spend rather less than £2 million a year in raising the grants (to offset the effects of inflation) and in making the means test more tolerable The only really satisfactory way of operating such a test would be to make it depend on the amount of disposable income—i e, what is left after paying all obligatory expenses including taxes The Ministry's new arrangements do not do this they conveniently forget that payment of taxes is quite an important obligation Also the basis of the calculation remains merely the annual income—regardless of whether the parent has plenty of capital or none But unquestionably the new rules are a step in the direction of fairness, and they should make it easier for more of the clever children of medical parents to get the same education as their clever coevals from "under-privileged" homes

COST OF CHLOROTHIAZIDE

WE feel we should clarify the matter of the cost of chlorothiazide mentioned in our recent leader on oral diuretics (May 10) We put the basic cost to the N H S of 8 g at 9*s* 10½d., but Mr J H Fingerhut, of Merck, Sharp and Dohme Ltd., manufacturers of chlorothiazide ('Saluric'), wrote in our issue of May 17 (p 1078) to say that this was wrong the correct figure, he said, was 7*s* 6*d* for 8 g He did not make it clear, however, that the discrepancy between the two figures was entirely due to the removal of purchase tax as from April 1 For the purposes of pricing, the change became effective on May 1 and a prescription for saluric written on May 10 (the date of our leader) would have carried a net cost price of 7*s* 7*d* per 8 g Thus, we were ten days out of date in the price we gave But readers should know that the reduction in the price of chlorothiazide was due to the beneficence of the Treasury

The *total* cost to the N H S of 8 g of chlorothiazide is now made up as follows

Basic cost plus on-cost	9*s*	5 57*d*
Dispensing fee	1*s*	2*d.*
Container allowance		1 55*d*
Total (to nearest 1*d*)	10*s*	9*d*

University of Cambridge

Lord Adrian has been re-elected vice-chancellor for 1958–59

University of Liverpool

On July 4 the honorary degree of M CH ORTH will be conferred on Sir Walter Mercer

University of Durham

Dr J K Russell has been appointed professor of midwifery and gynæcology in the Newcastle division from Oct. 1 in succession to Prof Harvey Evers

Dr Russell, who is 39 years of age, graduated in medicine at Aberdeen in 1942 From 1943 to 1946 he served with the Royal Air Force medical branch On demobilisation he returned to Aberdeen, and after holding gynæcological and obstetrical house-appointments he became registrar at the Aberdeen Maternity Hospital He took the M R C.O G in 1949, and a year later he went to Newcastle as first assistant in obstetrics and gynæcology in the University of Durham He was appointed senior lecturer in the department in 1956, and he is also consultant obstetrician and gynæcologist to the United Newcastle Hospitals He was elected F R.C.O G last month. With colleagues in the departments of child health, pathology, and medicine, he has studied various hazards to the life of the fœtus in late pregnancy and early in the neonatal period

University of Birmingham

Dr D V Hubble has been appointed to the chair of pædiatrics in succession to Dr J M Smellie, who retires at the end of September

Dr Hubble qualified from St Bartholomew's Hospital in 1924, and after holding house-appointments there he joined Dr F G Lescher in practice in Derby Soon afterwards he was appointed to the staff of the Derbyshire Royal Infirmary, the Derby City Hospital, and the Derbyshire Children's Hospital He is an examiner in medicine in the University of Sheffield and a member of the medical committee of the Sheffield Regional Hospital Board He is also a member of the council of the Association of Physicians and of the British Pædiatric Association He was elected F R C P in 1954 His published work reflects his interest in metabolism, endocrinology, pædiatrics, and genetics and includes papers on Cushing's syndrome, homœostasis, familial cretinism, the adrenogenital syndrome, and glycogen storage disease of the liver He is also eminent as a Johnsonian and has published studies on Charles Darwin as a practising invalid

Prof R A McCance will deliver the Leonard Parsons lectures in 1959

University of Edinburgh

Mr John Boyes, professor of oral surgery in the University of Durham, has been appointed to the chair of dental surgery in succession to Prof A. C W Hutchinson, and is expected to take up his appointment in October

Professor Boyes, who is 45 years of age, was educated at George Watson's College, Edinburgh, the School of Medicine of the Royal Colleges, Edinburgh, and the Edinburgh Dental Hospital and School He took the L D S in 1934 and his medical qualification the following year After holding appointments as school dental officer to Ayr County Council and resident dental house-surgeon at the Middlesex Hospital, London, he joined the staff of the Bangour Hospital, West Lothian, where from 1940 he held the appointment of resident surgical and dental officer to the plastic and jaw injury unit In 1945 he took the F R C.S E., and the same year he became first assistant in the department of oral pathology of the Sutherland Dental Hospital, Newcastle upon Tyne He was appointed in 1946 to the Nuffield chair of oral medicine in the University of Durham He is also director of the Newcastle Dental Hospital and dental surgeon to the Royal Victoria Infirmary

Royal College of Surgeons of England

Buckston Browne Dinner—Accommodation at this dinner (tickets £2 10s) is limited and fellows or members who wish to attend should write immediately to Mr W F Davis, deputy secretary of the college, Lincoln's Inn Fields, London, W C 2

Guy's Hospital Medical School, London

On Monday, Aug 11, at 1 P M at the medical school, London Bridge, S E 1, Dr E P Cronkite of the Brookhaven National Laboratory will speak on some effects of ionising radiation on human beings

International Congress of Angiology

This congress will be held in San Remo, instead of in Venice as formerly announced, from Sept 24 to 28 Further information may be had from the secretariat of the congress, dermatological clinic, University of Pisa, Italy

Beit Fellowships for Medical Research

Prof G F Marrian has been elected a member of the advisory board in place of Dr C H Andrewes, who retires after fourteen years' membership

The following elections to junior fellowships (£900 a year) have been made

Phoebe M Cotes, M B , PH D Lond (at the medical unit, University College Hospital Medical School, London), J G Nicholls, M B , PH D Lond (at the department of physiology, University College, London), G M A Gray, PH D Lond (at the department of biochemisty, Lister Institute of Preventive Medicine, London), J B Gurdon, B A Oxon (at the department of zoology and comparative anatomy, University of Oxford), Margarethe M A Holzbauer, M D Graz, PH.D Edin (at the department of pharmacology, University of Edinburgh), F H Taylor, PH.D Lond (at the physical chemical laboratories, department of chemistry, Imperial College, London)

Bristol in 1930, John Coates held house-appointments at Bristol General Hospital In 1935 he took the M R C P and his M D with distinction Soon afterwards he returned to Bridgwater to take over the family practice on his father's retirement Later he became honorary medical officer to Bridgwater General Hospital

During the late war he served with the R A M C He spent most of his time in the Middle East, and, with the rank of lieut-colonel, was medical adviser to the Persia and Iraq Commands After he returned to civilian life he decided to specialise in pædiatrics, and held an appointment as senior resident medical officer at the Victoria Hospital for Children in Chelsea before returning to Somerset Soon afterwards he was appointed to the staffs of Musgrove Park Hospital and Yeovil Hospital

H P writes

Notes and News

WORLD HEALTH ASSEMBLY

At the World Health Assembly, which opened in Minneapolis, Minnesota, on May 30 after a session commemorating the tenth anniversary of the World Health Organisation,[1] Dr Leroy E Burney, surgeon-general of the U S Public Health Service, was elected president Dr Burney declared that W H O 's role should be fourfold (1) to coordinate and help strengthen research through scientific meetings and the dissemination of literature, (2) to aid in training health personnel, (3) to help reduce the lag between the discovery and the application of new methods of diagnosis and treatment, and (4) to enlist the participation of groups outside the traditional health setting—such as occupational, welfare, social, and education workers Dr Burney presented the Leon Bernard Foundation prize to Dr Thomas Parran, now dean of the Graduate School of Public Health in the University of Pennsylvania

In the debate on the Director-General's annual report for 1957 Prof V M Zhdanov (Soviet Union) indicated his delegation's approval of the emphasis on the eradication of communicable diseases such as malaria He added that the Soviet Union, with its vast facilities for the control of communicable diseases, in the form of both institutions and specialised personnel, was ready to accept medical workers from abroad for training and to send its own staff to other countries to help further such campaigns He praised the work of W H O 's influenza centres in dealing with the pandemic of 1957 and the achievements of the W H O Expert Committee on Poliomyelitis The U S S R was ready, he said, to participate in this exchange of scientific information

A budget of $14,300,000 for 1959, proposed by Dr M G Candau, director-general of W H O, was approved unanimously by the two main committees In the past ten years W H O 's income has expanded steadily from $5 million A report by W H O 's external auditor revealed that 97 08% of contributions to the 1957 regular budget had been received from active member States—the highest percentage since the Organisation's inception The Executive Board submitted a proposal to encourage contributions to the World Malaria Fund from all possible sources Dr T W Tewari said that India's malaria-control campaign had now been transformed into an eradication campaign, with 230 anti-malaria teams in the field, India would pay the entire running costs The Assembly elected Tunisia to designate a person to serve for a year on the Executive Board, to complete the three-year term of the member designated by Syria, now that that country has merged with Egypt to form the United Arab Republic At a meeting of the programme and budget committee, several delegates deplored the fact that the high cost of vaccine prevented them from organising extensive poliomyelitis-immunisation programmes

AN INJUSTICE MITIGATED

The rules governing grants to boys and girls who win State scholarships have been grossly unfair to many parents, because of its means test In principle there ought to be no means test any parent who pays his required contribution to the community, in the form of taxes, should be entitled to whatever the community offers in the way of educational benefits, and it is paradoxical that the more a parent pays into the common chest, the less he can hope for any help out of it But, theory apart, the system has led to quite patent injustice in practice because the means test itself has been unrealistic In deciding how much the father of a State scholar shall pay, not only have the allowances for his other expenses borne little relation to the facts, but the scale for fixing his contribution has become progressively more severe as his income increases—so that he has sometimes paid " a second surtax "

Consequently some parents—especially in the professional range of earnings—have found themselves with too large an

income to qualify for a grant but too small an income to pay for a university education for their son or daughter Few parents, unless they have capital, can now afford to send more than one, or possibly two, children to the university in the absence of any kind of grant; and in families clever enough to have several State scholars the only way in which university education could be secured for all of them has been for the father to retire from work—or from life. "I could not have gone to the university if my father had not died", some students have said.

---

[1] See *Lancet*, June 7, 1958, p 1234

The Ministry of Education is now to spend rather less than £2 million a year in raising the grants (to offset the effects of inflation) and in making the means test more tolerable. The only really satisfactory way of operating such a test would be to make it depend on the amount of disposable income—i.e., what is left after paying all obligatory expenses including taxes The Ministry's new arrangements do not do this they conveniently forget that payment of taxes is quite an important obligation. Also the basis of the calculation remains merely the annual income—regardless of whether the parent has plenty of capital or none. But unquestionably the new rules are a step in the direction of fairness, and they should make it easier for more of the clever children of medical parents to get the same education as their clever coevals from "under-privileged" homes

COST OF CHLOROTHIAZIDE

WE feel we should clarify the matter of the cost of chlorothiazide mentioned in our recent leader on oral diuretics (May 10) We put the basic cost to the N.H S of 8 g at 9s 10½d.; but Mr J H. Fingerhut, of Merck, Sharp and Dohme Ltd., manufacturers of chlorothiazide ('Saluric'), wrote in our issue of May 17 (p 1078) to say that this was wrong the correct figure, he said, was *7s 6d* for 8 g He did not make it clear, however, that the discrepancy between the two figures was entirely due to the removal of purchase tax as from April 1 For the purposes of pricing the change became effective on May 1 and a prescription for saluric written on May 10 (the date of our leader) would have carried a net cost price of *7s 7d* per 8 g Thus, we were ten days out of date in the price we gave. But readers should know that the reduction in the price of chlorothiazide was due to the beneficence of the Treasury

The *total* cost to the N.H S of 8 g of chlorothiazide is now made up as follows:

Basic cost plus on-cost	9s. 5·57d.
Dispensing fee	1s 2d.
Container allowance	1·55d.
Total (to nearest 1d.)	10s 9d.

University of Cambridge

Lord Adrian has been re-elected vice-chancellor for 1958–59

University of Liverpool

On July 4 the honorary degree of M.CH.ORTH. will be conferred on Sir Walter Mercer

University of Durham

Dr J K. Russell has been appointed professor of midwifery and gynæcology in the Newcastle division from Oct. 1 in succession to Prof Harvey Evers

Dr Russell, who is 39 years of age, graduated in medicine at Aberdeen in 1942. From 1943 to 1946 he served with the Royal Air Force medical branch. On demobilisation he returned to Aberdeen, and after holding gynæcological and obstetrical house-appointments he became registrar at the Aberdeen Maternity Hospital. He took the M.R.C.O G in 1949, and a year later he went to Newcastle as first assistant in obstetrics and gynæcology in the University of Durham. He was appointed senior lecturer in the department in 1956, and he is also consultant obstetrician and gynæcologist to the United Newcastle Hospitals. He was elected F.R.C.O G last month. With colleagues in the departments of child health, pathology, and medicine, he has studied various hazards to the life of the fœtus in late pregnancy and early in the neonatal period.

University of Birmingham

Dr. D V Hubble has been appointed to the chair of pædiatrics in succession to Dr. J M. Smellie, who retires at the end of September.

Dr Hubble qualified from St. Bartholomew's Hospital in 1924, and after holding house-appointments there he joined Dr F G Lescher in practice in Derby Soon afterwards he was appointed to the staff of the Derbyshire Royal Infirmary, the Derby City Hospital, and the Derbyshire Children's Hospital He is an examiner in medicine in the University of Sheffield and a member of the medical committee of the Sheffield Regional Hospital Board. He is also a member of the council of the Association of Physicians and of the British Pædiatric Association. He was elected F.R.C.P in 1954. His published work reflects his interest in metabolism, endocrinology, pædiatrics, and genetics and includes papers on Cushing's syndrome, homœostasis, familial cretinism, the adrenogenital syndrome, and glycogen storage disease of the liver He is also eminent as a Johnsonian and has published studies on Charles Darwin as a practising invalid

Prof R A McCance will deliver the Leonard Parsons lectures in 1959

University of Edinburgh

Mr. John Boyes, professor of oral surgery in the University of Durham, has been appointed to the chair of dental surgery in succession to Prof A. C. W Hutchinson, and is expected to take up his appointment in October

Professor Boyes, who is 45 years of age, was educated at George Watson's College, Edinburgh, the School of Medicine of the Royal Colleges, Edinburgh, and the Edinburgh Dental Hospital and School He took the L.D.S. in 1934 and his medical qualification the following year. After holding appointments as school dental officer to Ayr County Council and resident dental house-surgeon at the Middlesex Hospital London, he joined the staff of the Bangour Hospital West Lothian, where from 1940 he held the appointment of resident surgical and dental officer to the plastic and jaw injury unit. In 1945 he took the F.R C.S.E., and the same year he became first assistant in the department of oral pathology of the Sutherland Dental Hospital, Newcastle upon Tyne He was appointed in 1946 to the Nuffield chair of oral medicine in the University of Durham. He is also director of the Newcastle Dental Hospital and dental surgeon to the Royal Victoria Infirmary.

Royal College of Surgeons of England

Buckston Browne Dinner.—Accommodation at this dinner (tickets £2 10s.) is limited and fellows or members who wish to attend should write immediately to Mr W F Davis, deputy secretary of the college, Lincoln's Inn Fields, London, W C.2.

Guy's Hospital Medical School, London

On Monday, Aug. 11, at 1 P.M. at the medical school, London Bridge, S.E 1, Dr E. P Cronkite of the Brookhaven National Laboratory will speak on some effects of ionising radiation on human beings

International Congress of Angiology

This congress will be held in San Remo, instead of in Venice as formerly announced, from Sept. 24 to 28. Further information may be had from the secretariat of the congress, dermatological clinic, University of Pisa, Italy

Beit Fellowships for Medical Research

Prof G F Marrian has been elected a member of the advisory board in place of Dr C. H. Andrewes, who retires after fourteen years' membership

The following elections to junior fellowships (£900 a year) have been made

Phoebe M Cotes, M.B , PH.D Lond (at the medical unit, University College Hospital Medical School, London) J G Nicholls, M.B., PH.D Lond (at the department of physiology, University College, London), G M A. Gray, PH.D Lond (at the department of biochemistry, Lister Institute of Preventive Medicine, London), J B Gurdon, B.A. Oxon (at the department of zoology and comparative anatomy, University of Oxford), Margarethe M. A Holzbauer, M.D Graz, PH.D Edin (at the department of pharmacology, University of Edinburgh), F H Taylor, PH.D Lond (at the physical chemical laboratories, department of chemistry, Imperial College, London)

Bristol in 1930, John Coates held house-appointments at Bristol General Hospital In 1935 he took the M R C P and his M D with distinction Soon afterwards he returned to Bridgwater to take over the family practice on his father's retirement Later he became honorary medical officer to Bridgwater General Hospital

During the late war he served with the R A M C He spent most of his time in the Middle East, and, with the rank of lieut -colonel, was medical adviser to the Persia and Iraq Commands After he returned to civilian life he decided to specialise in pædiatrics, and held an appointment as senior resident medical officer at the Victoria Hospital for Children in Chelsea before returning to Somerset Soon afterwards he was appointed to the staffs of Musgrove Park Hospital and Yeovil Hospital

H P writes

I first met John Coates nearly thirty years ago when we were members of the " house " at the Bristol General Hospital Already he was acquiring the great learning that marked him out He was reading deeply in the underlying philosophy of medicine at an academic standard outside the range of other housemen He was determined to lay firm foundations of a wide mastery of medicine, and to this end spent several years as a resident in general medicine and surgery and in the special departments None the less, then as through all his life, he kept the " common touch ", and was a delightful and cheery companion His room was a meeting-place where shop chatter mixed with music, both lowbrow and classical

After the war he specialised as a pædiatrician, and his name rapidly became identified with this specialty from Yeovil to Minehead and from Glastonbury to Taunton His centre and pride were his pædiatric wards at the Taunton and Somerset Hospital, but he was called to all the hospitals around He paid for his success in having little time to call his own It was a ready saying at social parties that if the 'phone went it was sure to be for " Jackie " His colleagues entrusted him with the postgraduate studies of their area, and the weekend courses he organised were a pleasure to both attending practitioners and lecturers He will be missed for his wise medical counsel, his care of the illnesses of the children of his colleagues, and the friendship and hospitality he and his wife provided for their many friends

Appointments

CARR, G R, CH M Manc, M D Michigan, F R C S consultant surgeon, *Stockport and Buxton group of hospitals*

CHADWICK, D L, M D Manc, F R C S, D L O part-time consultant E N T surgeon, Crumpsall, Ancoats, and Manchester Ear Hospitals

Notes and News

WORLD HEALTH ASSEMBLY

AT the World Health Assembly, which opened in Minneapolis, Minnesota, on May 30 after a session commemorating the tenth anniversary of the World Health Organisation,[1] Dr Leroy E Burney, surgeon-general of the U S Public Health Service, was elected president Dr Burney declared that W H O 's role should be fourfold (1) to coordinate and help strengthen research through scientific meetings and the dissemination of literature, (2) to aid in training health personnel, (3) to help reduce the lag between the discovery and the application of new methods of diagnosis and treatment, and (4) to enlist the participation of groups outside the traditional health setting—such as occupational, welfare, social, and education workers Dr Burney presented the Leon Bernard Foundation prize to Dr Thomas Parran, now dean of the Graduate School of Public Health in the University of Pennsylvania

In the debate on the Director-General's annual report for 1957 Prof V M Zhdanov (Soviet Union) indicated his delegation's approval of the emphasis on the eradication of communicable diseases such as malaria He added that the Soviet Union, with its vast facilities for the control of communicable diseases, in the form of both institutions and specialised personnel, was ready to accept medical workers from abroad for training and to send its own staff to other countries to help further such campaigns He praised the work of W H O 's influenza centres in dealing with the pandemic of 1957 and the achievements of the W H O Expert Committee on Poliomyelitis The U S S R was ready, he said, to participate in this exchange of scientific information

A budget of $14,300,000 for 1959, proposed by Dr M G Candau, director-general of W H O, was approved unanimously by the two main committees In the past ten years W H O 's income has expanded steadily from $5 million A report by W H O 's external auditor revealed that 97 08% of contributions to the 1957 regular budget had been received from active member States—the highest percentage since the Organisation's inception The Executive Board submitted a proposal to encourage contributions to the World Malaria Fund from all possible sources Dr T W Tewari said that India's malaria-control campaign had now been transformed into an eradication campaign, with 230 anti-malaria teams in the field, India would pay the entire running costs The Assembly elected Tunisia to designate a person to serve for a year on the Executive Board, to complete the three-year term of the member designated by Syria, now that that country has merged with Egypt to form the United Arab Republic At a meeting of the programme and budget committee, several delegates deplored the fact that the high cost of vaccine prevented them from organising extensive poliomyelitis-immunisation programmes

AN INJUSTICE MITIGATED

THE rules governing grants to boys and girls who win State scholarships have been grossly unfair to many parents, because of its means test In principle there ought to be no means test any parent who pays his required contribution to the community, in the form of taxes, should be entitled to whatever the community offers in the way of educational benefits, and it is paradoxical that the more a parent pays into the common chest, the less he can hope for any help out of it But, theory apart, the system has led to quite patent injustice in practice because the means test itself has been unrealistic In deciding how much the father of a State scholar shall pay, not only have the allowances for his other expenses borne little relation to the facts, but the scale for fixing his contribution has become progressively more severe as his income increases—so that he has sometimes paid " a second surtax "

Consequently some parents—especially in the professional range of earnings—have found themselves with too large an

come to qualify for a grant but too small an income to pay r a university education for their son or daughter Few parents, less they have capital. can now afford to send more than e, or possibly two, children to the university in the absence any kind of grant; and in families clever enough to have veral State scholars the only way in which university educa- n could be secured for all of them has been for the father retire from work—or from life. "I could not have gone to e university if my father had not died", some students ve said

---

[1] See *Lancet*, June 7, 1958, p 1234

The Ministry of Education is now to spend rather less than 2 million a year in raising the grants (to offset the effects of flation) and in making the means test more tolerable. The ly really satisfactory way of operating such a test would be make it depend on the amount of disposable income— e., what is left after paying all obligatory expenses cluding taxes The Ministry's new arrangements do not do is they conveniently forget that payment of taxes is quite n important obligation. Also the basis of the calculation emains merely the annual income—regardless of whether the arent has plenty of capital or none. But unquestionably the ew rules are a step in the direction of fairness, and they hould make it easier for more of the clever children of medical arents to get the same education as their clever coevals om "under-privileged" homes

COST OF CHLOROTHIAZIDE

WE feel we should clarify the matter of the cost of chloro-hiazide mentioned in our recent leader on oral diuretics May 10) We put the basic cost to the N.H.S of 8 g at s 10½d.; but Mr J H. Fingerhut, of Merck, Sharp and Dohme Ltd., manufacturers of chlorothiazide ('Saluric'), wrote n our issue of May 17 (p 1078) to say that this was wrong. the orrect figure, he said, was *7s 6d* for 8 g He did not make it lear, however, that the discrepancy between the two figures was ntirely due to the removal of purchase tax as from April 1 or the purposes of pricing the change became effective on May 1 and a prescription for saluric written on May 10 (the late of our leader) would have carried a net cost price of *7s 7d* per 8 g Thus, we were ten days out of date in the price we gave. But readers should know that the reduction in the price of chlorothiazide was due to the beneficence of the Treasury

The *total* cost to the N.H.S of 8 g. of chlorothiazide is now made up as follows-

Basic cost plus on-cost	9s	5·57d.
Dispensing fee	1s	2d.
Container allowance		1·55d.
Total (to nearest 1d.)	10s	9d.

University of Cambridge

Lord Adrian has been re-elected vice-chancellor for 1958–59

University of Liverpool

On July 4 the honorary degree of M.CH.ORTH. will be conferred on Sir Walter Mercer

University of Durham

Dr J K. Russell has been appointed professor of midwifery and gynæcology in the Newcastle division from Oct. 1 in succession to Prof Harvey Evers

Dr Russell, who is 39 years of age, graduated in medicine at Aberdeen in 1942. From 1943 to 1946 he served with the Royal Air Force medical branch. On demobilisation he returned to Aberdeen, and after holding gynæcological and obstetrical house-appointments he became registrar at the Aberdeen Maternity Hospital. He took the M.R.C.O.G in 1949, and a year later he went to Newcastle as first assistant in obstetrics and gynæcology in the University of Durham. He was appointed senior lecturer in the department in 1956, and he is also consultant obstetrician and gynæcologist to the United Newcastle Hospitals He was elected F.R.C.O G last month. With colleagues in the departments of child health, pathology, and medicine, he has studied various hazards to the life of the fœtus in late pregnancy and early in the neonatal period.

University of Birmingham

Dr D V. Hubble has been appointed to the chair of pædiatrics in succession to Dr J. M. Smellie, who retires at the end of September

Dr Hubble qualified from St. Bartholomew's Hospital in 1924, and after holding house-appointments there he joined Dr F G Lescher in practice in Derby Soon afterwards he was appointed to the staff of the Derbyshire Royal Infirmary, the Derby City Hospital, and the Derbyshire Children's Hospital He is an examiner in medicine in the University of Sheffield and a member of the medical committee of the Sheffield Regional Hospital Board. He is also a member of the council of the Association of Physicians and of the British Pædiatric Association. He was elected F.R.C.P. in 1954 His published work reflects his interest in metabolism, endocrinology, pædiatrics, and genetics and includes papers on Cushing's syndrome, homœostasis, familial cretinism, the adrenogenital syndrome, and glycogen storage disease of the liver. He is also eminent as a Johnsonian and has published studies on Charles Darwin as a practising invalid.

Prof R A. McCance will deliver the Leonard Parsons lectures in 1959.

University of Edinburgh

Mr John Boyes professor of oral surgery in the University of Durham, has been appointed to the chair of dental surgery in succession to Prof A. C. W. Hutchinson, and is expected to take up his appointment in October

Professor Boyes. who is 45 years of age, was educated at George Watson's College, Edinburgh, the School of Medicine of the Royal Colleges, Edinburgh, and the Edinburgh Dental Hospital and School He took the L.D.S. in 1934 and his medical qualification the following year After holding appointments as school dental officer to Ayr County Council and resident dental house-surgeon at the Middlesex Hospital, London, he joined the staff of the Bangour Hospital, West Lothian, where from 1940 he held the appointment of resident surgical and dental officer to the plastic and jaw injury unit. In 1945 he took the F.R.C.S.E., and the same year he became first assistant in the department of oral pathology of the Sutherland Dental Hospital, Newcastle upon Tyne. He was appointed in 1946 to the Nuffield chair of oral medicine in the University of Durham. He is also director of the Newcastle Dental Hospital and dental surgeon to the Royal Victoria Infirmary

Royal College of Surgeons of England

Buckston Browne Dinner—Accommodation at this dinner (tickets £2 10s) is limited and fellows or members who wish to attend should write immediately to Mr. W F Davis, deputy secretary of the college, Lincoln's Inn Fields, London, W C.2.

Guy's Hospital Medical School, London

On Monday, Aug. 11, at 1 P.M. at the medical school, London Bridge, S.E 1, Dr E. P Cronkite of the Brookhaven National Laboratory will speak on some effects of ionising radiation on human beings.

International Congress of Angiology

This congress will be held in San Remo. instead of in Venice as formerly announced, from Sept. 24 to 28 Further information may be had from the secretariat of the congress, dermatological clinic. University of Pisa, Italy

Beit Fellowships for Medical Research

Prof. G. F. Marrian has been elected a member of the advisory board in place of Dr. C. H. Andrewes, who retires after fourteen years' membership

The following elections to junior fellowships (£900 a year) have been made

Phoebe M Cotes. M.B., PH.D Lond. (at the medical unit, University College Hospital Medical School, London), J G Nicholls, M.B., PH.D Lond (at the department of physiology, University College, London), G M. A. Gray, PH.D Lond (at the department of biochemistry, Lister Institute of Preventive Medicine, London), J B Gurdon, B.A. Oxon. (at the department of zoology and comparative anatomy, University of Oxford), Margarethe M A Holzbauer, M.D Graz, PH.D Edin (at the department of pharmacology, University of Edinburgh), F H. Taylor, PH.D Lond (at the physical chemical laboratories, department of chemistry, Imperial College, London)

British Medical Association

Entries are invited for the occupational health prize (£50) and the Katherine Bishop Harman prize (£75) for research into the disorders incident to maternity Further particulars may be had from the secretary of the Association, B M A House, London, W C 1

Association of Sea and Air Port Health Authorities of the British Isles

This Association will hold its annual meeting in Edinburgh, on Thursday and Friday, June 19 and 20 The speakers will include Sir Kenneth Cowan and Dr J B Maguire Further particulars may be had from the Medical Officer of Health, Health Department, Civic Centre, Southampton

Nutrition Society

This society will hold a symposium on applied nutrition, at Queen Elizabeth College, Campden Hill Road, London, W 8, on Friday, July 11 The speakers will include Sir Zachary Cope and Dr J J O'Dwyer Further particulars may be had from Miss D F Hollingsworth, c/o Ministry of Agriculture, Fisheries and Food, Great Westminster House, Horseferry Road, S W 1

Association for Radiation Research

This Association, which has grown out of the Radiation Research Visiting Club, has been formed to bring together research workers of different disciplines with a common interest in radiobiology, radiation chemistry, and radiation physics Dr L H Gray has been elected chairman, Dr C L Smith hon treasurer, and Miss T Alper (experimental radiopathology research unit, Hammersmith Hospital, Ducane Road, London, W 12) hon secretary

Margery Fry Memorial Fund

THE Howard League for Penal Reform invites donations to a trust fund which is to be created in memory of Margery Fry, one of whose chief interests was the prevention of crime and the rehabilitation of offenders It is intended that the fund shall be used for such purposes as the financing of scholarships and research and of pioneer projects for the rehabilitation of offenders, and perhaps to help in setting up an institute of criminology One of the signatories of the appeal is Dame Janet Vaughan, and the treasurer is Mr John Cole, 66, Lincoln's Inn Fields, London, W C 2

Convention on Social Security with Yugoslavia

A convention on social security between the United Kingdom and Yugoslavia has been signed The agreement will cover the benefits provided by the schemes of national insurance, industrial injuries insurance, and family allowances in this country and the corresponding benefits in Yugoslavia Medical treatment provided under the Yugoslav scheme of health insurance will be available in Yugoslavia to people insured under the United Kingdom national insurance scheme and to their dependants whether working or on holiday there The convention will come into operation when it has been ratified, and this date will be announced later

Home for Mentally Handicapped Children

THE Scottish Association of Parents of Handicapped Children is a small voluntary body which was formed four and a half years ago in Glasgow It has already set up a small day centre for mentally handicapped children whom the education authority had not accepted for admission to occupational centres It is now opening (*Glasgow Herald*, May 26) at Craigrownie Castle, Cove, Dunbartonshire, a short-stay home for these children The castle was given to the Association as a free gift, but £7000 was needed to convert it, and the Association had only £400 in cash Much of the work of conversion was done by members and their friends, who also raised enough money to enable the home to receive the first children at the of May It is planned for the home to take 25 children, years and under, for periods of up to eight weeks

Dr W M Court Brown has been awarded a David Anderson-Berry prize and medal by the Royal Society of Edinburgh

Sir Vivian Fuchs is to give an illustrated lecture on his journey to the South Pole at the London Coliseum on Sunday, Sept. 28, at 7 30 P M, in aid of the funds of the National Varicose Foundation Some tickets (5*s*, 7*s* 6*d*, 10*s* 6*d*, 15*s*, £1 1*s*, £2 2*s*) are being reserved for doctors and their families Applications, marked "doctor", should be sent with the money to the treasurer of the Foundation, York Road, S W 11

The annual dinner and dance of the Postgraduate Medical School and *Hammersmith Hospital Association will be held at the Park Lane* Hotel at 7 45 P M on Friday, July 4 Tickets may be had from *Dr D* Abelson, department of medicine, Postgraduate Medical School of London, Ducane Road, London, W 12

The summer dinner of the Oxford Graduates' Medical Club will be held in Merton College, Oxford, on Friday, July 4, at 7 30 P M Dr A M Cooke will be in the chair Members may bring medical men or women as guests Tickets (37*s* 6*d*) may be had before June 25 from Dr Ronald Macbeth, department of otolaryngology, Radcliffe Infirmary, Oxford

The Hospitals' Symphony Orchestra is giving a concert at B M A House, London, W C 1, on Wednesday, July 2, at 8 P M Tickets (3*s* 6*d*, 5*s*, 7*s* 6*d*) can be had from Miss M A Whipp, South Western Hospital, Landor Road, S W 9

The British Diabetic Association is holding an exhibition from June 25 to 28, at Central Hall, Westminster, of some of the foods, products, and equipment which are now available to help diabetics with their diet and daily routine The exhibition will be open daily from 11 A M to 9 P M

A booklet on *Nursing for Men* (No 89) has been published in the Central Youth Employment Executive's Choice of Career series Copies may be had from H M Stationery Office (1*s* 6*d*)

The Board of Registration of Medical Auxiliaries has published a new edition (1957-58) of its register of chiropodists Doctors may obtain free copies from the Board, B M A House, Tavistock Square, London, W C 1

A draft British Standard for X-ray envelopes is being circulated for technical comment to industry and others concerned Views on this document should be submitted before June 25 to the British Standards Institution

---

Diary of the Week

JUNE 15 TO 21

Monday, 16th

POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W 12
4 P M Dr Brian Ackner Attempted Suicide

Tuesday, 17th

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W C 2
5 P M Mr A J Helfet Mechanism of the Derangements of the Medial Meniscus of the Knee (Hunterian lecture)
INSTITUTE OF DERMATOLOGY, Lisle Street, W C 2
5 30 P M Dr A D Porter Light Sensitivity

Wednesday, 18th

POSTGRADUATE MEDICAL SCHOOL
2 P M Dr T M Pollock *Control of Tuberculosis by B C G* Vaccination
INSTITUTE OF DERMATOLOGY
5 30 P M Dr Henry Haber Eosinophilic Granulomata
INSTITUTE OF DISEASES OF THE CHEST, Brompton, S W 3
5 P M. Mr J R Belcher Surgery of Carcinoma of the Bronchus

Thursday, 19th

ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W 1
2 30 P.M *Urology* Dr W F Whitmore (New York) Surgical Treatment of Bladder Tumours
ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 26, Portland Place, W 1
7 30 P M Prof A W Woodruff *Medicine in China Today*
POSTGRADUATE MEDICAL SCHOOL
4 P M Prof Clifford Wilson Prognosis in Bright's Disease
CIBA FOUNDATION
5 P M (Royal Institution, 21, Albemarle Street, W 1) Prof F Bourlière (Paris) Comparative Study of Age Changes (Ciba Foundation lecture)
BRITISH ASSOCIATION OF UROLOGICAL SURGEONS HOME AND OVERSEAS, 47, Lincoln's Inn Fields, W C 2
9 30 A M *Opening of three-day meeting*
HYPNOTHERAPY GROUP
8 P M. (1, Wimpole Street W 1) Dr Louis Rose, Dr J A Hadfield Paranormal Healing

Friday, 20th

POSTGRADUATE MEDICAL SCHOOL
10 A.M Mr James Hardman Surgery of Intracranial *Hæmorrhage*

ENVIRONMENTAL FACTORS IN RESPIRATORY DISEASE *

D D Reid
M D Aberd, Ph D Lond
READER IN EPIDEMIOLOGY AND VITAL STATISTICS,
LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, LONDON, W C 1

In the study of respiratory disease in its community setting, I have followed Milroy's precepts "that more diligent and continued attention may be paid than has yet been attempted in this country to the study of the accurate *Geography of Diseases*" and that this must be combined with *Chronology*—the exact timing of the appearance, persistence, and aggravation of disease—"so that some record of its varying natural history may be preserved for the benefit of future times"

Respiratory Illness in Offices

Experience in the epidemiology of tuberculosis has taught us the hazards of the widening circle of human contacts which the child meets on leaving the sheltered environment of home and school It seems sensible, therefore, to apply the methods of collaborative inquiry already used in the schoolroom surveys to investigate environment and respiratory disease in offices where so many spend their working life Accordingly Dr Robert Williams and I set up a small pilot inquiry, designed to exploit bacteriological and clinical methods of studying the occurrence and spread of common colds in London offices of the General Post Office (Reid, Williams, and Hirch 1953)

During an epidemic season, histories of all respiratory affections were elicited by regular weekly inquiry from the staffs working in these offices At the same time, samples of the office air were taken by the slit-sampler method The resulting count both of general bacterial air contaminants and of *Strep salivarius*, which is used as an indicator of air pollution by organisms ejected from the mouth, were plotted against the incidence curve of colds among the office staff Observations of outdoor temperature and indoor humidity were made and charted in the same way

The time sequence of events thus observed was clear enough The sudden autumnal fall in outside temperature coincided with a shutting of windows to maintain a stable indoor temperature The *Strep salivarius* count rose in step with a sharp increase in the incidence of colds This in turn coincided with the outbreak of an epidemic of colds in other members of the G P O staff in the rest of London, and it was followed, about two weeks later, by a rise in the notification-rate of acute pneumonia in the the general population of London

The epidemic conundrum is—does the sudden change in climate precipitate an epidemic of colds and their major sequelæ by prompting the shutting of windows and increasing the pollution of the air by organisms from the throats of the occupants so that colds spread more readily from one to another? Or, if we discount the possibility of virus mutation, does the change, perhaps in temperature or humidity, alter host resistance to minimal infections and multiply the frequency of clinically apparent disease? The problem of the epidemic effects of temperature change has been discussed by writers back to Hippocrates, but it has been more recently studied in the present context of London by workers such as Young (1924), Woods (1928), and the Payling Wrights (1945) The Payling Wrights showed very clearly that the weekly mortality-rate from bronchopneumonia in children under 2 years of age was highly correlated with a fall in the temperature two weeks before They inclined to the view that the climatic change upset the epidemic balance more by lowering resistance than by increasing the ease of spread Our recent work supports that proposition

In the family studies, for example, colds were rather more common among the less adequately clad children Again, a seasonal increase in the secondary-attack rates within households, based on clinically obvious infections, was not paralleled by any contemporary increase in the apparent rate of passage of the indicator organisms from person to person Yet some such increase might have been expected to result from an increased rate of transmission of infection In the schools the incidence of colds was lower in classrooms which were usually kept at higher temperatures Although, in offices, the higher *Strep salivarius* content of the air certainly suggested that the *conditions of poorer ventilation in cold weather might* favour aerial transmission of disease, the whole drift of the evidence appears to minimise the importance of this means of spread in the common cold Carefully controlled observations on the immediate past history of those with acute coryza were consistent with the popular belief that being exposed to chilling was significantly related to the onset of clinically obvious infection In short, it seems likely that the sudden climatic change at the approach of winter precipitates apparent disease among the carriers of an infection which then spreads rapidly by close-range droplet spray or intimate contact through a population made susceptible both by the sudden cold and the low endemic level of infection during the summer

Climatic Change and Air Pollution

Whatever its origin, this seasonal wave of minor respiratory infections is but the forerunner of much more serious respiratory illness, which is certainly related in time to the seasonal changes in temperature and other associated aspects of climate When, however, to the more usual changes in climate are added the sudden temperature inversion and humidity of fog, the whole pattern of morbidity and mortality can alter dramatically The smog disaster of 1952 is the most recent and alarming example, but the medical statisticians at the General Register Office from Farr to Logan (1953) have reported fogs in London which have been associated with excesses in mortality ranging from a few hundreds to four thousand

Reviewing the experience of the years 1870–91, Russell (1926) concluded that the sudden rise in the respiratory-disease death-rate noted in the fogs of that period were more likely to be due to the drop in temperature which always accompanied these fogs than to any other environmental characteristic But when the temperature falls, other changes in habit and environment occur for instance, fires are stoked up and there is an increase in the atmospheric pollution The peak of mortality during the London fog of 1952 was much more closely associated with a rapid increase in air pollution, measured by the sulphur-dioxide content of the air, than with contemporary changes in temperature or humidity (Wilkins 1954)

---

* The second Milroy lecture for 1957, delivered before the Royal College of Physicians of London on Feb 7, 1957 The first lecture appeared last week.
